CALIFORNIA with its 50,000,000 acres of high mountains over 2,500 feet elevation, and 1,000 miles of ocean coast, is a paradise for the lover of the out-of-doors. As soon as schools close in the early summer, travel starts for seashore and mountain, reaches its peak on the Fourth of July, and as suddenly ends on Labor Day. In that 60 day period the highways that now penetrate the mountain canyons hum with autos of between 300,000 and 500,000 people. The great majority of vacationists congregate in established public camps and cabin tracts, numbering well over 1,000 and occupying approximately 1,000 miles on about 100 streams. Near the large cities of the South, 5,000 people may travel up the ordinary canyon on hot week-ends. In one canyon the record is 30,000. In winter, snow sports also draw huge week-end crowds to at least 3 of the mountain camp-grounds, thus making a year-round problem.

Though a few camps are located on mountain sides or ridges for vista views, most campers stay near the streams, partly for the convenience of water supply, but also because in the semi-

arid West running water is so much a rarity that the sight of it in the green mountains satisfies the soul. Perhaps this preciousness of water explains why the people have responded so readily to programs for keeping the streams and mountains clean.

Up to about 1915, mountain recreation was primitive in character and reserved for the true nature lover. Roads into the mountains were mere wagon trails, so steep, narrow and tortuous that only venturesome spirits undertook them, and one had the whole out-of-doors to choose from for a stopping place.

With the close of the World War conditions changed. Increased ownership of autos caused the fine highways of the valleys to be pushed farther into the mountains, and presently city people scattered to them. At first there was no restriction or restraint. The army of tenderfoot campers flitting here and there soon desecrated the mountains with papers, cans, and garbage.

It was fortunate, however, that nearly all the popular areas fell in the 19,000,000 acres of California National Forest, and therefore were under U. S. Forest Service with its fine body of rangers, commanding the respect and admiration of the public.

A program decided on by them with

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

the health authorities to change the dangerous habits of the campers embraced in essence, sanitary placarding of roadsides and camp sites; closing large areas to the public on the grounds of fire protection; the requirement that campers hold campfire permits issued by the Rangers; and concentrating the crowds in properly equipped camp areas.

Of the placards, the most useful read:

"Leave your camp as you would like to find it. Burn or bury all refuse. Keep the pleasure grounds of America clean.

California State Board of Health "

"Pollution of Streams is Unlawful

Violation of the *State Sanitation Laws* is a misdemeanor punishable by *Fine* or *Imprisonment*. Within the National Forests the United States Forest Service aids the State in the enforcement of these laws.

All persons on the National Forests are warned to *Commit No Nuisance* whereby a stream may be defiled. *Burn* or *Bury* all camp refuse. Keep your own camp clean and report all violations of the laws to the Forest Ranger.

California State Board of Health
United States Forest Service "

"DANGER

DO NOT DRINK THIS WATER WITHOUT
BOILING IT.

California State Board of Health "

The last sign was posted along streams that had become contaminated. It probably brought home to the campers the ruination they were committing.

Concentrating the campers in fewer places made the handling of the sanitary problem and fires economical, and in fact possible. It has been a fixed policy of the Forest Service to establish more and more of these public camp grounds at favored spots. There are now close to 500 of them in the 18 Forests comprising California.

There are, however, still about 1,500,000 acres in the higher mountains, reached only by trail, that are reserved

for primitive recreation. Here the true camper and nature lover sports as in the past, but the great crowds throng to the public camps. With each season the code of the mountains gains converts. The sanitary program has become remarkably successful. The Forest Service Officials tried putting a tactful and persuasive patrolman in several of its heavily used public camp grounds, in lieu of many maintenance crews to clean up after parties had left. His task was to go from camp to camp, putting in a word for leaving the place clean and keeping the streams pure. It was found that fewer men were needed for the clean-ups than formerly were required.

Next in point of acreage and use are the intensively used National Parks under the Department of Interior. These aggregate some 1,200,000 acres and are located in Yosemite, Sequoia, Lassen, and Grant National Forest. In addition, the Department of the Interior has a number of smaller National Monuments, where there is more or less picnicking. There are also a number of comparatively small but intensively used state parks, acquired in the past few years by the State Division of Parks.

There are about 6,000,000 acres of mountain lands in private ownership, and several thousand have recreational attraction. Here the problem of sanitation falls entirely on the health officer.

The setting aside of the public lands in the National Forests 30 to 50 years ago was purely to conserve water and timber. In the mountains just behind our present meeting place is the First National Forest created in California, the San Gabriel Timberland Reserve, proclaimed by President Harrison to conserve water, on December 20, 1892. However, until the President's Conference of 1920 on outdoor recreation and recreational resources of federal lands, the Forest Service shut its eyes

to recreation. That was the turning point. By 1931 recreation was on a plane as important as forest conservation, and the wilder and more scenic portions of canyon and mountain have been set aside for recreation.

The slogan is "The Greatest Good for the Greatest Number." In the South, watershed, stream protection, and recreation come first. The principle is guiding, even into the detailed use of a recreational area. Thus priority of use is given to public camps, municipal camps, charitable organizations, schools, stores, and cabins, in substantially that order.

The use of the National Forests for summer cabins began in a small way along about 1910, when individuals secured permission to use small plots of ground for that purpose. With the swell of travel into the mountains after the war, there came a great demand for these cabin sites. To reduce the fire hazard, the Forest Service became a subdivider and set aside tracts which it has surveyed into plots of approximately $\frac{1}{2}$ acre each.

These lots are leased under "Special Use Permits," at a charge of \$15 to \$40 a year, depending on the use and the term of the permit. There are now over 6,000 permittees. Each permittee does all his own building, and associations do more or less of the development work. The tendency is to put permits on a yearly term and to get away from commercial permits. Furthermore, the Forest Service is more particular to go into the experience and finances of the permittees, to avoid "shoestring" enterprises.

Apparently it was never anticipated that this cabin development in the mountains would assume large proportions or create a sanitary menace. Even now setback requirements from streams and roads are not specified, though the permits specify a 10 foot setback from exterior boundaries of the lot so as to

avoid congestion. Sanitary programs for the protection of streams have been very much handicapped on this account. Often the cabins will be found at the water's edge.

The permits are terminable, and termination is not contestable. However, the Forest Service aims to terminate them only for good cause or violation of the numerous conditions contained in the permits. Certain of the sections specify the minimum cost of the cabin, usually \$500; others regulate garbage disposal and latrines, and require all possible precautions to prevent pollution of waters in the tract. Because camp grounds are being increased and they clash with the cabin sites, and because eastern congressmen and the public look askance at "Special Use Permits," it seems cabin and commercial use will decline.

The cabin and commercial problem of the future is more apt to be found on the privately owned lands within or adjacent to the National Forests. In San Bernardino County mountains alone, it is understood there are some 9,000 cabins on private lands as against 3,000 on Forest Service land.

One finds wide extremes in the conveniences provided in the different mountain recreation areas. As a rule the National and State Parks, all of which happen to be in the northern or central part of the state, are the best equipped, having water under pressure in cabins and camp, camp garbage collection and water flushed sewerage except where outlying camps may use some other methods, usually chemical toilets.

Sanitary requirements vary widely in the National Forest, as each district has its own supervisor with much local authority. Those near the large cities in the South are generally the best equipped, while Forests farther away are primitive.

In the best developed camps and

cabin tracts in the National Forests, piped water is brought to convenient places. But generally water must be carried from its source, which, in the northern and central portions of the state, is a natural spring or side creek, and in the South is generally the main stream through the camp. A common device in the camp is to dig a small hole along the stream and dip water from it.

Since showers are almost unknown, and water-flushed toilets are usually restricted or not allowed, water requirements are not much over 5 gallons per head per day.

In order to control water resources for future development, the Forest Service now files on all water it can get, and holds to land leading to water-bearing ground. Associations of cabin owners are encouraged by the Service, to help put over programs for piping the water. At one time the Service encouraged the Associations to do their own filing, but this is now regarded as unwise.

Garbage disposal is well done. It is rare now to find cans and refuse along the streams and camp grounds. Cabin owners and primitive camps bury the garbage and feed the edible portion to the "birds and bears." A few of the better equipped camps are provided with garbage cans and garbage is collected by the Forest Rangers. The Rangers find, however, that it is almost impossible to have enough cans to take care of heavy week-end crowds, and people will drop their refuse on the ground. The majority of the camps have large garbage pits, which are provided with tight board covers and periscope inlets. When a pit fills up it is abandoned and a new pit is dug.

The point of the title of this paper relates to the disposal of refuse and human excreta and the effect on mountain streams. Next to fire prevention, protection of streams is probably the highest requirement that has been set.

Not only do the streams in the regions that are popular with the public suggest by their pristine clearness a purity that should be preserved, but they are all used for irrigation and town purposes by some 3,000,000 people. Probably 500,000 people receive the water inside of 10 to 20 miles of flow from recreation areas. Even closer at hand the streams are many times the water supply of the vacationists themselves.

Canyons are narrow and sides are precipitous, so that space for sewage disposal is at a premium. Cabins are often close to streams or perched on hillsides.

Soil conditions do not vary as much as one might suppose. The prevailing types are fine-grained, loose and ashy, or more or less coarse decomposed granite. The latter is found mainly in canyon bottoms. If not too cemented it makes an excellent medium to absorb sewage. Bedrock is of course variable in depth and fissuring, but is generally shallow, and the soil may be interlaid with huge boulders. Depth to subterranean water is also variable. In meadow spots the ground may be springy or waterlogged at certain seasons, and of course cesspools, or almost all sewerage devices, are dangerous. In one such area chemical toilets are required and contents must be hauled away.

Leaving out Yosemite Park, Arrowhead Lake, and a couple of small parks, there are no sewer systems and no streams of sewage to be thought of. Under such circumstances, Forest Rangers and health officers go to extremes to preserve the streams safe enough to drink. In the South, evidently simply through fear of underground pollution, wated flushed toilets have not been allowed in the canyons belonging to the Forest Service, and one district does not allow them anywhere on its lands for fear of water-shed pollution. In one of the counties they are

forbidden by ordinance, if disposal is less than 100 feet from any stream, spring, or vein of water, but may be installed under permit for the next 400 feet. In these areas swimming in streams is also forbidden.

Elsewhere in the National Forests the Rangers allow a good deal of latitude in particular cases where it is felt there is no danger to streams. So far as possible, local health officers try to hold private lands to the same restrictions as prevail on adjacent National Forests, but they can go only so far as the law allows in refusing the right to a water flushed system in the absence of actual menace. The public resorts frequently have water flushed systems. Kitchen slops and lavatory water are run into cesspools or scattered on the ground, and appear to create no problem.

In place of water flushed systems, dry vault privies or chemical toilets are accepted or even required. One of the National Forests has devised a unique vault privy, using an upright elliptical can support for the seat, and an ingenious cross-flue at the head of the upright vent better to utilize natural draft and improve ventilation. It is said to remove practically all odors.

Chemical toilets are reported as not measuring up to expectations, but those who advocate them contend that they are still the best method of disposal of dry excreta, and that they require the least supervision, and of course no water. The principal difficulty is that they require more attention than can be reasonably expected, to accomplish the theoretically perfect results claimed for them. In heavily used camps the container soon fills and a nasty juice leaks out on the ground. The cesspools to receive cleanings have received woefully inadequate care as to location and operating conditions. Some people complain bitterly of odors from the bowls and use them only under compulsion.

What the future holds for sewage disposal methods in the mountains is a question. It is expected that people will want their water flushed fixtures in their vacation places. This means more liberal water supply and undoubtedly a higher degree of supervision of operation than at present, greater care in the location of camps and cabins and of the sewage disposal, and utilization of all safeguards against stream pollution.

Sanitary supervision is now extremely meager and non-technical in the mountains, considering the populations and interests involved. The best is probably to be found in the National Parks where the Public Health Service gives engineering supervision in policies, design and operation. The National Forests must depend on state and local health authorities and on its Rangers. The Forest Ranger aims to give each cabin an examination for fire-proofing, garbage disposal, and condition of toilets, before June 1, and again at the close of the season, to decide on any changes necessary before the next year. During the rush season there is little time for inspection except on receipt of complaints.

The state and local health departments are not even able to do as much inspection as the Rangers. In this respect Los Angeles County fares best. It has the most complete local health service, and the county building department checks plans for cabins and buildings. Also in the canyons used for water supply of Pasadena, a coöperative arrangement between the city and county health departments has recently provided a special inspector. He has made a systematic survey to map premises, and has taken occasional samples of creeks and wells. Comparing National Forests, North and South, the latter have many more full-time health departments to draw upon. All commercial auto camps are under the State Immigration and Housing

TABULAR COMPARISON OF *B. Coli* ANALYSES OF STREAMS IN MOUNTAIN RECREATION AREAS

Commission which makes occasional inspection for general sanitation as well as housing.

Considering the fact that the whole sanitary program revolves around keeping the streams clean, it is strange that so little time is spent on noting and studying the performance of leaching methods of disposal in the few places where they are used, and that practically no analytical work, and none that is systematic, has been done to determine the actual state of purity of the streams. The most convincing evidence of which I am aware is from the brief but systematic sampling by this Bureau in the summers of 1930, 1932, and 1933, of 20 mountain streams popular with vacationists, in which 102 samples were taken. By accident, half the streams and practically half the

samples were taken from streams in the highly protected National Forests in the South and along the southeast slope of the Sierras. The others were in the somewhat larger streams of the Sierras from Bakersfield to Placerville, where leaching methods of sewage disposal, and swimming are not objected to *per se*.

A comparison of the results shows that there is substantially no difference in the cleanliness of the two sets of streams, nor do the analyses by streams show any significant difference one from another. Even the few somewhat higher values probably signify merely poor sampling, as a high result did not carry to lower sampling points. Indications are that the higher results signify *B. aerogenes*. It is doubtful if at any place the water was really at a "danger point" for drinking.

Public Health Education Technics of Special Experiences*

Newspapers

WILLIAM FORD HIGBY, F.A.P.H.A.

Secretary, California Tuberculosis Association, San Francisco, Calif.

DURING the last half century the format and character of the American newspaper has completely changed. Personal journalism has passed. The newspaper, even in a city of 20,000, is a highly capitalized industry.

There was a time when any person filled with enthusiasm could start a newspaper with a capital of a thousand dollars. Today a metropolitan paper is worth millions. In the days of personal journalism, newspapers were financed by their subscribers; today they are financed by their advertisers, and depend upon advertising for their existence.

Frequently we hear the railings of the uninformed against the policy of newspapers. They say: "Newspapers stress arson, rape, and murder. They pump up the filth from the sewers of the world and dump it on their front pages. They should print educational matter, the things people should read, the things that would make a better world in which to live."

In every city of any size such papers have been started and have perished because they could not get the circulation to get the ads to pay for the cir-

culation to bring sweetness and light into the American home.

Before there were any educational psychologists the editors of our daily press caught that intangible moving mood of the American people and printed what the people wanted to read.

In San Francisco a hot 8 column line will increase street sales by 10,000. Consistent failure to make the front page play that will capture the interest of the people, will cost circulation, and circulation is the life blood of a paper. The play of the news reflects the desires of a given population. We may resent the charge but the facts remain.

Banner lines, heads, sub-heads and picture captions have deservedly received adverse criticism from our sensitive health administrators as well as others occupying for a brief moment the spotlight in the daily parade.

But there are mechanical and verbal difficulties interposed between a good story and its head. Some day, when you have finished what you think is a particularly brilliant speech or paper, try to describe all you have said in 3 lines of 12 letters, and spaces in each—no more, no less—and include a verb that ties it together perfectly. The wonder is that headlines reflect so well the contents of stories. It is readily apparent why it is that a good copy desk man can solve a cross-word puzzle as fast as he can write, and why 90

* Read before the Public Health Education Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 4, 1934.

per cent of all such puzzles, during the height of the craze, were dashed off by these men while they were waiting for copy.

Factors other than mechanical difficulties stand between the head lines and the story. Scientific men seldom commit themselves to definite statements. Like lawyers, they always have a trap door from which they can crawl and file a new brief. News can be stated in categorical affirmatives, and whether they like it or not, it will be so stated.

Once an epidemiologist was interviewed on the efficiency of health work in rural counties. Every sentence was carefully qualified, but he was unquestionably pointing out weaknesses in the health work of his state. After eagerly awaiting the appearance of the paper, he was mortified to read:

RURAL HEALTH
CHIEFS SHOWN
FLAT FAILURE

Health authority shows peril to citizens who pay taxes for health protection.

When you use the newspaper to send out health information, you must remember you are using a rifle and not a shot gun. You must use a sharp nosed bullet fired with high powered ammunition and aimed with telescopic sights at a specific target. You must learn to hit the bull's-eye. Unlike the marksman on the rifle range, it is difficult to determine how accurate the shots are.

A press clipping bureau is only the record of the ammunition used. It is no indication of the accuracy of the shot fired; it simply shows that the copy has passed the editor and in his judgment may hit the target, but a published story is by no means an indication that you have made a bull's-eye. Publicity directors, I know, will pardon me for betraying a trade secret.

Too many of us write copy as we prepare circular letters. If we want

our material to get the best chance possible in the competition of the news of the world, I suggest that all copy be prepared as either exclusive or unduplicated for all papers. Most of us prepare a story, mimeograph it, and send it to all the papers of our city, county, or state. This method brings results, but experience has proved that greater results can be produced if each paper is treated as an individual.

Newspapers vary with the community, and as between city and county, as do mercantile establishments. In the leading city of a rural county you will find the newspaper corresponding to the general store, where the proprietor and his clerks sell everything from a spool of thread to a tractor. In the metropolis you will find the newspaper which corresponds to the department store where lingerie for young ladies up to 14 years is sold on the fifth floor, and for those above that age, on the first floor. In hundreds of communities where the only evidence of gregarious life is a wide place in the road, we have the Weekly, unquestionably the most influential paper of them all.

In the large communities we have a further obstacle to general copy, the evening paper and the morning paper. This difference is often overlooked. We might liken the evening paper to the emergency hospital, where the patient is rushed for first aid, and the morning paper to the general hospital where there is time for proper diagnosis and treatment. As many people die in the emergency hospital, so many stories die in the evening paper. The evening paper is a flash, the morning paper a controlled flame. Complicating the task of the copy writer is the foreign language press, district papers, and class publications.

Avenues for health information are open in metropolitan papers to carefully prepared copy in Sunday and special editions, newspaper magazine sections,

rotogravure, and illustrated feature pages, in book review pages, and in the auto and sports and society sections.

A good picture will carry a poor story. Learn to use a camera and always have it with you. Cultivate young amateurs who are clever at taking pictures. Frequently, the posed picture is a flop. Generally speaking the picture of either a malnourished health official with a bald head, or a fat one with flat feet, is not the best method of promoting, by graphic art, the principles of health education. These pictures are appropriate only in the de luxe annual report, printed at the expense of the tax payer.

There are no rules about newspaper art which I have the temerity to outline before a scientific gathering. One rule only will I give. Clip all the 2, 3 and 4 column art in a given paper for a week. Analyze their appeal and if you wish to take a postgraduate course, study Freud.

Many standard texts are available which give the mechanics of preparing copy. Mechanical structure of newspaper copy must be fully understood. It must not be neglected, but given a sound background, there is no guarantee of success any more than a brilliant career is assured the graduate of an art school who has mastered form, color, and the technic of mixing paints.

Copy must have a punch. As the reader quickly passes his eye over the pages of his paper, the lead of your story must signal his brain to stop, look, read. When your copy reaches print you have entered a contest for a prize—the attention of the reader. It is a contest between champions, and 5 minutes after tossing aside the paper only the winners are remembered. The field is forgotten. Someone has said, "Nothing is as dead as yesterday's paper."

We are discussing, this afternoon, the various avenues open for the dissemina-

tion of health education. We must never forget the limitations of each of our media. Devise ways to use every one of these avenues systematically; do not make the mistake of thinking that the newspaper is your only medium or that all messages can be given through its columns. The newspaper should be the mirror which reflects your public relations campaign. A newspaper story must be news, and news is something that has just happened or is about to happen. The life span of a news story is very brief. Many of us try to make octogenarians of something whose life span does not exceed 6 hours.

No editor ever turns down a good news story, but he prints your propaganda with a frown on his face and a curse in his heart. It is his way of trying to be a good fellow, but he loses respect for you.

We have given one rule for the preparation of copy—it must have what the editors call punch. The only other rule we shall give is that it must be short. If a man is drowning he cries, "Help!" That is all that is necessary.

Julius Caesar would have been a great newspaper man had he lived today. In describing his Gallic campaign he wrote: "Veni, Vidi, Vici." It took the Victorian historians 6 volumes to describe the same campaign. A reporter once sent by his city editor to cover an address, returned flushed with enthusiasm: "Hot stuff, worth a column." The city editor held up his thumb and index finger about an inch apart and said: "Fifty words." The reporter bubbling over started to protest. He was rudely interrupted by the editor who said, "Kid, the biggest story that ever broke in the history of the world was the Crucifixion of Jesus Christ, and John reported it in 350 words."

We said before that unduplicated and exclusive copy produced the best results; of course, it takes more labor,

time, and thought, but if we are looking for efficiency, it is worth the effort. We have attempted to show that newspapers of the same class have different personalities, and that there are many differences between different types of papers and departments of the same paper.

Copy should be written with these interests, differences, and prejudices in mind.

A good newspaper man can hang up his hat in any shop in the country and in a few days get the feel of the paper,

instinctively grasp the S.O.B. list and identify himself like a chameleon with his surroundings.

The copywriter of health information should so identify himself with the intangible personality which is represented by the paper for which he is writing, that when his name appears on the upper left hand corner of the copy, the editor knows he need go no further but in the rush of the day can shoot the story to the copy desk without re-write or slash. In other words, he accepts you as a member of his staff.

Local Boy Makes Good in a Big Way

THIS traditional headline of the country paper seems to apply to a son of up-state New York. He is Dr. Sylvester Maxwell Lambert, of Ellen-ville, who now has a practice of some 1,000,000 patients in 8,000,000 square miles of sea and land in the Pacific Ocean. As related in the *American Magazine*, he is director of the medical work of the Rockefeller Foundation in the islands of the Pacific Ocean—a roving commission with a variety of duties. Treatment, by internal medicine and injections, of hookworm and yaws, two of the worst scourges of the tropics, comes first. Then he teaches the principles of hygiene and sanitation to the natives and assists the various island governments to coördinate their medical departments into one service.

Dr. Lambert reports that the natives of the Pacific islands, formerly reported dying out, are now increasing. He said to John W. Vandercook, writer of the article:

Hookworm happens to be easily curable.

It didn't used to be. In 1921 Dr. Maurice C. Hall, zoölogist of the Bureau of Animal Industry of the U. S. Department of Agriculture, found that a small dose of carbon tetrachloride, one of the cheapest, simplest things on earth (dry cleaners use it instead of gasoline), would clean out, at once, 90 per cent of a patient's hookworm parasites.

Having something like that to peddle, believe me, makes travel easy. The work of the Foundation and the government—this health business is done on a partnership basis, of course—did more to civilize Malaita, I think, than all the missionaries and punitive expeditions of 50 years.

I suppose you don't care a darn about the Native Medical School! But it's more important than all this stuff put together. It's the first of its kind in the world—a school where natives receive a full course in modern medicine so they can go back and teach their own people. It's located here in Suva.

All the students are Pacific Island natives. Forty students are enrolled. In exchange for their tuition they must serve their own people. It's a tough job we're giving them—to apply modern medicine, in some cases to people just emerging from the Stone Age. But these boys can do it.

New York State J. Med. 35, 2:55 (Jan. 15), 1935.

Virulence Tests for Typhoid Bacilli and Antibody Relationships in Antityphoid Sera*

JOHN F. NORTON, PH.D., F.A.P.H.A., AND JOHN H. DINGLE, Sc.D.

The Upjohn Company, Kalamazoo, Mich.

VARIATION and dissociation in the enteric group of bacteria are accompanied by changes in antigenic properties^{1, 2, 3}; and such changes may, in turn, affect the value of these variants or dissociants for prophylactic purposes. Relative virulence of these organisms also may be associated with dissociation and correlated with antigenic activity.

The lack of sensitive and convenient methods for determination of virulence and of antibody relationships in antisera produced against typhoid bacilli of established virulence has led to the following experimental work. Particular emphasis has been placed on the measurement of protective action of the antisera in an attempt to determine whether there is a correlation of such activity with some known and easily determinable property of the antisera and whether this property may be correlated with antigenic components of the organisms being studied. Methods for determination of virulence of typhoid bacilli and for measurement of protective action of antityphoid sera are presented, together with preliminary data obtained by these methods.

I. VIRULENCE TESTS

In the early work with typhoid bacilli it was found that large numbers of living bacilli would kill the common laboratory animals—mice, guinea pigs, and rabbits—but that strains of the bacillus varied in this respect. Pfeiffer and Kolle⁴ found that freshly isolated strains of typhoid bacilli had a lethal power for guinea pigs 2 to 10 times that of old laboratory strains. Kutscher and Meinicke⁵ obtained one highly virulent culture which killed guinea pigs in a dose of 1/100–1/200 loop.

Goyle⁶ in a study of the normal and rough strains of *Salmonella enteritidis*, found that the normal form was the more virulent for mice, and also that the filtrate of an autolysed culture of the normal strain was more toxic than that prepared from the rough strain.

Arkwright,⁷ in studying paratyphoid and typhoid organisms, showed that smooth strains were considerably more virulent than rough, but that there was little difference in virulence between the smooth-non-motile and the smooth-motile forms. He further pointed out that the somatic O or S (stable) antigen of normal and smooth forms was common to virulent and absent from avirulent types, and that the H antigen, associated with flagella, and present in SM and RM forms appeared to have little influence on virulence.

* Read before the Laboratory Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 4, 1934.

Balteanu,⁸ in his work on *Vibrio cholerae*, obtained a non-flagellated variant of the vibrio which showed apparently the same virulence as the normal flagellated organism.

Ledingham⁹ noted that the intraperitoneal injection of 2 c.c. of a 48 hour broth culture of an "avirulent" typhoid bacillus failed to kill guinea pigs, whereas 1 c.c. of a recently isolated smooth strain was lethal.

Webster and Burn,¹⁰ in a study of the relative virulence of smooth, mucoid, and rough strains of *B. enteritidis*, concluded that the smooth type was of relatively high pathogenicity for mice and that the mucoid and rough variants were markedly less virulent. Furthermore, the phage-resistant variants (S, mucoid, or R) were all less virulent than the usual smooth-susceptible strains.

Larkum,¹¹ in a study of 6 strains of *B. typhosus* Rawlins obtained from different sources, found only one of these strains to be typically smooth in its reactions. Three of the remaining 5 cultures, together with known R and S cultures were tested for virulence in guinea pigs by intraperitoneal injection of growth from two 18 hour slants. Only one strain and the R control failed to kill.

Shwartzman³ attempted unsuccessfully to raise the virulence of a strain of *B. typhosus* by 53 mouse passages. He noted, however, that rough strains were less virulent than their parent stock strains, and that mouse passage caused a change in reacting powers and antigenicity, as evidenced by the local skin reactivity, with or without loss in agglutinability.

Grinnell¹² found that both smooth motile and smooth non-motile strains of *B. typhosus* were approximately 100 to 1,000 times more virulent for mice, as judged by intraperitoneal killing power and resistance to bactericidal action, than motile or non-motile rough strains. He concluded that it was impossible to

express accurately the difference in the virulence of various strains as a difference in m.l.d. since the per cent mortality with smooth strains decreased very slowly as the dose was reduced.

Perry, Findlay, and Bensted,¹³ however, obtained strikingly consistent results in mice by intraperitoneal inoculation of 18 hour broth cultures. The m.l.d. (amount to kill 100 per cent of mice in 48 hours) of the Rawlins strain was ascertained to be 500 millions, and that of 2 recently (2 years) isolated smooth strains to be 40 millions. In a rough condition, however, one of these latter strains killed only 14 per cent of the mice with such dosage. The virulence and smoothness of the Rawlins strain was found to be markedly increased by 3 mouse passages and the m.l.d. was reduced from 500 millions to 40 millions, accompanied by the development of a pure smooth strain.

Maltaner¹⁴ injected living rough and smooth variants of *B. typhosus* intravenously into rabbits and demonstrated that only smooth variants possessed invasive properties as determined by development of the carrier state, whereas no difference could be detected in toxicity or power to produce rapid death by this method.

Felix and Pitt²⁴ concluded from their work that the intraperitoneal virulence of *B. typhosus* for mice was intimately associated with resistance to the action of the O antibody. Inagglutinable smooth strains were highly virulent, while agglutinable smooth strains were of low virulence. Rough strains were found to be of low virulence.

In earlier experiments, we made an attempt to develop a virulence test for typhoid bacilli by intraperitoneal injection of mice. A counted suspension of the growth from an 18 hour agar culture was used. The m.l.d. for our culture of the Rawlins strain was found to be approximately 1,600 million organisms, and that for a recently isolated

smooth strain, No. 99, to vary between 300 and 500 million organisms. The m.l.d. of our culture of the 0901 strain was slightly greater than 400 million organisms.

These results led to the conclusion that, although this method showed wide difference in virulence, the large number of organisms required for an m.l.d. indicated insufficient sensitivity for the detection of relatively slight differences in virulence. It seemed desirable to secure a method which would produce death with fewer organisms than is required by the intraperitoneal route. Intracerebral injection seemed to provide such a method.¹⁵

Technic of Test—The organisms used were (1) *B. typhosus* No. 99, a recently isolated smooth, motile strain, (2) *B. typhosus*, Rawlins, the Public Health Service strain obtained by us in 1919, an intermediate type with colonies irregular in outline but not typically rough, and (3) *B. typhosus*, 0901, the Felix strain, from which we obtained a smooth, non-motile culture.

The bacterial suspensions were prepared as follows: Growth from an 18 hour agar slant was suspended in 10–20 c.c. of physiological saline and the number of organisms per c.c. determined by direct count in a Helber counting chamber. The suspension was then diluted so as to contain 2,000 million organisms per c.c. Serial dilutions, designed to give the desired number of organisms in the infecting dose, were prepared just prior to injection.

Adult white mice of 15–20 gm. average weight were used. Intracerebral injections of mice were performed under ether anesthesia. Although the mice could tolerate an intracerebral dose having a volume of 0.1 c.c., the infecting dose chosen was contained in a volume of 0.05 c.c., so as to minimize physical injury and yet retain reasonable accuracy in measuring the volume.

The results obtained in terms of

m.l.d. by intracerebral administration of organisms were as follows: The m.l.d. for *B. typhosus* No. 99 was fixed at 20,000 organisms. Below this figure death occurred in varying percentages of the mice inoculated. For *B. typhosus*, Rawlins, an m.l.d. of 20,000,–000 organisms was obtained. *B. typhosus*, 0901, gave an m.l.d. of 2,000,–000 organisms.

Symptoms and Autopsy Findings *—

A constant syndrome was produced in the mice following the intracerebral injection of organisms. Recovery from the anesthesia and shock of injection was ordinarily quite rapid. Symptoms of infection—lassitude, roughing of fur, anorexia, tendency to lean against cage or lie down, diarrhea in some animals—usually appeared within 6 to 8 hours or not until 24 hours. For a few hours prior to the animals' death, a markedly increased response to stimuli was noted. If recovery took place, either no symptoms were observed or they were of a day's duration, seldom lasting beyond 24–36 hours. The majority of the mice died within 48–72 hours, but occasional deaths occurred up to 7 days. With one exception, mice surviving this period have not succumbed to the infection at a later date.

On autopsy, some subcutaneous hemorrhage was occasionally seen at the site of injection. Upon removal of the skull, the surface of the brain tissue usually appeared congested and somewhat hemorrhagic. Gross dissection of the brain tissue showed a definite congestion and generalized or localized hemorrhage, and there was a noticeable softening of the tissue itself. Microscopically, the picture was one of acute disseminated encephalitis. Multiple microscopic foci of acute inflammatory infiltration were found, both within the cerebral hemispheres and within the

* We are indebted to Dr. N. W. Larkum and to Dr. Hazel R. Prentice for aid in the pathological examinations.

cerebellum. Some of these foci showed marked hemorrhage. Beneath the meninges there was a similar exudate. No marked evidence of degeneration in tissue apart from the foci of infection was present. Other organs and tissues showed no gross pathological changes.

Smears of the brain tissue from fatally infected mice showed relatively large numbers of bacilli, and a considerable number of white blood cells. Phagocytosis of bacilli was usually present to some degree. Gram stains showed characteristic short Gram-negative rods, usually occurring singly.

Culture of the brain yielded profuse growth of typhoid bacilli in pure culture. The organism also was isolated from the spinal cord in the lower thoracic and lumbar regions. Heart blood cultures were negative—only 1 of more than 100 autopsied mice yielded positive results.

In order to determine whether or not multiplication had taken place, one group of mice was killed by etherization at intervals up to 2 hours following injection and compared with a second group allowed to succumb to the infection. Equivalent quantities of the brain tissue from each group of mice were streaked on agar plates. Only occasional colonies were obtained from the brain tissue of etherized mice in contrast to the profuse growth obtained from the mice expiring as a result of the infection. The same contrast was noted in stained smears.

Strains after mouse passage gave typical fermentation reactions, agglutinated with anti-typhoid serum (although in some cases to a lower titer than the original), and showed little change in colony morphology. After 3 passages through mice, using injections corresponding to the m.l.d., no detectable changes in colony morphology were noted in the 0901 and No. 99 strains. The surface of the Rawlins colonies seemed somewhat smoother but were still irregular in outline. The titer of O antibody in immune rabbit serum

produced with this organism after 3 mouse passages, however, was 8 times higher than that produced with the original strain.

Mice which survived the injections, either naturally or as a result of the protective action of immune serum, were killed and autopsied at weekly intervals. Cultures from the brain contained typhoid bacilli up to 5 or 6 weeks following the injection. Beyond this period, the results so far have been negative. Some of the strains so obtained were quite rough in character; others had not changed, at least in colony morphology. Further study of these cultures, as well as the pathological reactions involved, if any, is in progress. It is possible that a carrier condition has been encountered.

A series of mice were injected intracerebrally with 0.05 c.c. of physiological saline, a second series with killed organisms, and a third series with saline intracerebrally and living organisms intraperitoneally. Neither saline nor killed organisms (100 million) had any apparent effect upon the mice. The injection of 0.025 c.c. of saline intracerebrally did not increase the susceptibility of the mice to living organisms administered intraperitoneally.

Virulence of the typhoid bacillus for laboratory animals is judged by its ability to invade and multiply in the tissues of the animal, and to cause disease or death by toxic action. In both the intraperitoneal and intracerebral methods the organisms are introduced parenterally into the mouse. In the former, invasiveness and multiplication can be demonstrated by the presence of the organism in the blood stream and organs¹⁶ in increased numbers; in the latter, by the presence of the organism in the entire central nervous system, including the spinal cord, in increased numbers. A blood brain barrier is apparently effective in preventing the organisms from producing a bacteremia

and generalized invasion of the animal following intracerebral administration. In both cases, death is presumably caused by the toxicity of the growing and disintegrating organisms in the animal, since killed cultures and filtrates in equivalent quantities do not cause death.

No correlation was obtained between weight of the mice and resistance to the infecting dose; in fact, the average weight of animals surviving was slightly less than that of animals succumbing.

This method of determining virulence has yielded more satisfactory results in our hands than has the method of intraperitoneal inoculation used by Grinnell and by Perry, Findlay, and Bensted. Not only were we able to produce death with smaller numbers of organisms, but a greater difference could be detected in the virulence of different strains.

A summary is given in Table I of the m.l.d. determinations with these strains by both intracerebral and intraperitoneal inoculation. By the intracerebral method the recently isolated strain (No. 99) was 1,000 times more virulent than our Rawlins strain; by the intraperitoneal method it was 4 times more virulent. By the intracerebral method, No. 99 was 100 times more virulent than the 0901 strain; whereas it was but slightly more virulent by the intraperitoneal method. The 0901 culture was 10 times more virulent than the Rawlins by the intracerebral method and less than 4 times more virulent by the intraperitoneal method.

In a comparison of the results obtained in the two methods with each culture, the intracerebral route was 80 times more sensitive than the intraperitoneal route in the case of the Rawlins culture, more than 200 times in the case of the 0901 culture, and 20,000 times in the case of the No. 99 culture.

From these results it appears that the method is more favorable to the virulent culture and shows a greater sensitivity as the virulence of the culture becomes greater. However, the number of cultures examined so far has been small. Further work is being carried on with a larger number of cultures obtained from various sources and of varying degrees of virulence.

II. PROTECTION TESTS

The immunological significance of H and O antigens and rough and smooth forms of the enteric group of organisms is becoming more important as the knowledge of these factors increases. The work of Felix,¹⁷ and Felix and Olitski¹⁸ indicated that the bactericidal, opsonic, and complement-binding activities of immune serum are produced by the action of the smooth somatic antigen. Braun and Nodake,¹⁹ and Balteanu⁸ believe, however, that both flagellar and somatic antigens (ectoplasm and endoplasm of Braun) are involved in these reactions. Hofmeier²⁰ believes that both antibodies are important for complement-fixation and phagocytosis, but that only the somatic or endoplasmic antibody is of importance in the bactericidal action of immune serum.

TABLE I

<i>Method of Inoculation</i>	<i>Strain</i>	<i>m.l.d.</i>
Intracerebral	Old culture, intermediate colonies (Rawlins)	20,000,000
	Recently isolated culture, smooth colonies (No. 99)	20,000
	Old culture, smooth colonies (0901)	2,000,000
Intraperitoneal	Old culture, intermediate colonies (Rawlins)	1,600,000,000
	Recently isolated culture, smooth colonies (No. 99)	400,000,000
	Old culture, smooth colonies (0901)	> 400,000,000

In a study of the prophylactic value of vaccines prepared from rough and smooth forms of organisms, Ledingham²¹ found that guinea pigs immunized with either living or killed avirulent (rough) typhoid bacilli (unable to kill a guinea pig by intraperitoneal injection of 2 c.c. of a 48 hour broth culture) were not protected against the inoculation of 1 c.c. of a recently isolated smooth, virulent strain. In passive protection experiments with guinea pigs, he found that guinea pig serum prepared against either living or dead organisms showed protective action in the highest concentration (1 c.c. of undiluted serum) when the guinea pigs were injected with 1 c.c. of a 48 hour living broth culture of virulent *B. typhosus*.

Arkwright⁷ found that when guinea pigs were immunized with smooth and rough strains of *B. paratyphosus* A, the smooth vaccine gave protection, the rough did not in all cases and to a much less extent. Moreover, heating the S vaccine at 100° C. did not diminish its protective value. The same results were obtained with *B. typhosus* although to a lesser degree—the S vaccine, either motile or non-motile gave decidedly more immunity than the R motile.

Ibrahim and Schütze,²² in a study of the prophylactic value of the H, O, and R antigens of *Salmonella aertrycke*, and of the toxicity of its smooth and rough variants, found that a vaccine containing both H and O antigen gave the best and most prolonged protection in mice; whereas a vaccine from the rough variant, whether it contained H or not, was ineffective. He further noted, however, that heating an S vaccine to 100° C. in order to destroy the thermolabile H antigen reduced the prophylactic value of the vaccine, and he believes that this may be due to a coincidental damaging of the vaccine as an immunizing agent. He further found that autolyzed filtrates of the rough variant

were approximately one-fourth as toxic as those of the smooth variant.

Grinnell,²³ in a study of the bactericidal action of human serum after vaccination with rough and smooth strains of *B. typhosus*, found that vaccination with a smooth virulent strain caused a considerable increase in the bactericidal antibodies; whereas vaccination with a rough strain of *B. typhosus* Rawlins produced little or no increase in the bactericidal power of the blood, although agglutinins for the virulent strain were present. In further studies¹² he found that after immunization of mice with a smooth virulent strain, a mortality of only 5.4 per cent occurred following intraperitoneal injection of a smooth strain in a dose which killed 95 per cent of the control mice. After a similar immunization with a rough Rawlins culture, 91.6 per cent of the mice died.

Perry, Findlay, and Bensted,¹³ in a study of active immunization of mice with vaccines prepared from a Rawlins strain, and from smooth and rough variants of a virulent strain, found that the Rawlins vaccine gave little protection; whereas the vaccines from both the rough and the smooth variants gave marked protection although the smooth vaccine appeared somewhat more effective. Two minimum lethal doses of a smooth virulent strain constituted the test dose. In further studies of the protective power of undiluted rabbit antiserum for mice, these authors concluded that within the limits of the test there was evidence of relationship between the O titer and the protective power of the serum. Owing to the nature of the test, they found that it was not possible to judge the comparative values of sera having O titers of 1–250 and less. They also found that active immunity, judged by protection, could be produced in mice without agglutinin response. From these results they concluded that the bactericidal

property of the blood appeared to be the sole laboratory test that could be employed with any prospect of success. The results of bactericidal tests showed that the smooth vaccine was markedly superior in raising the bactericidal power of human blood, but that little difference could be noted between partially rough and markedly rough vaccines.

Maltaner,¹⁴ in a study of the prophylactic value of rough and smooth strains and the resultant immunity, found that vaccination of rabbits by the intravenous method with either rough or smooth variants gave protection against approximately 14 times the minimal invasive dose of smooth living bacilli as indicated by blood and bile cultures. The rough vaccines protected distinctly better than the smooth, although antisera prepared from flagellated and non-flagellated rough vaccines possessed no specific agglutinins for the smooth infecting strain, with the exception of flagellar agglutinins in the case of the flagellated vaccine. In both rabbits and guinea pigs, vaccination with either rough or smooth variants was found to produce marked phagocytic response to subsequent injection of living smooth organisms, whereas the response in control animals was slight.

Felix and Pitt,²⁴ in their latest work, have presented evidence of a new antigen, termed "Vi," which was present only in inagglutinable, smooth *B. typhosus* strains of high virulence. Antiserum produced by immunizing rabbits with living inagglutinable strains was capable of specifically clumping the inagglutinable organisms to a varying titer (1-100 to 1-400) depending upon the organism used. This titer was independent of the H and O titers; the antibody could not be removed by absorption with agglutinable strains, but was absorbed by inagglutinable ones. The virulent inagglutinable strains were markedly superior as antigens for active immuniza-

tion of mice. In passive protection experiments with mice the "Vi" antibody content seemed to determine the protective action of the antiserum, but was apparently unable to neutralize the toxicity of killed organisms. Neutralization of toxicity was attributed to the action of the O antibody.

The discordant results in the literature and the lack of an adequate method of measuring the protective action of antisera against typhoid bacilli of established virulence and antigenic composition have led to the following experimental work.

Attempts to measure the protective action of two antisera containing high titers in H and O agglutinins respectively were carried out using intraperitoneal injection into mice of both organisms and antisera. Marked protection was shown with both the antisera when low dilutions or relatively large amounts of antiserum were used for protection. When higher dilutions of the antisera were used, however, satisfactory comparisons could not be made, in confirmation of the results obtained by Perry, Findlay, and Binsted. It seemed likely that the inability of serum dilutions to protect might be due, in part at least, to the large numbers of organisms required for a minimum lethal dose by intraperitoneal injection. For this reason, experiments were carried out using the intracerebral injection of organisms to test the degree of protection afforded by the various antisera under examination.

Preparation of Immune Sera—Antityphoid sera were prepared in rabbits by two methods: (1) three intradermal injections of 0.1 c.c. of the bacterial suspension, standardized to contain 1,000 million organisms per c.c., were made at 7 day intervals; and (2) repeated intravenous injections of killed organisms and, finally, of living organisms, were given at 4 to 6 day intervals until a high agglutinin titer had de-

veloped. Bleedings were made 7 days following the last injection.

Agglutinin Titrations of Antisera—The H and O antibody content of the antisera was determined by titration with a rough variant of the Rawlins culture and a smooth non-motile variant of the 0901 culture. Typical flocculent and granular agglutinations were obtained with these suspensions. The usual agglutination technic was employed in these tests.

Bacterial Suspensions—The suspensions of smooth virulent typhoid bacilli for the test dose were prepared and standardized as described in the preceding section. The recently isolated smooth strain, No. 99, was used as the test organism.

Mouse Protection Tests Using Intracerebral Injection of Both Organisms and Antisera—Protection tests were carried out by injecting both organisms and antiserum, mixed just prior to injection. Inconsistent results were obtained, however, which were found to be due in part to a primary toxicity which some of the antisera exerted when administered by this route.

Preliminary experiments showed that protection against intracerebral injections of organisms could be obtained by intraperitoneal injection of antisera. Experiments were then carried out to determine the most satisfactory time interval between the injection of antiserum and the test dose of organisms.

Effect of Time Interval between Injection of Antiserum and Organisms—Antiserum was administered intraperitoneally to different groups of mice at intervals of 5 and 2 hours before the intracerebral injection of organisms, simultaneously with the organism injection, and 5 hours after the organism injection. No significant difference in the protective action could be noted when the antiserum was given before or simultaneously with the organisms, but somewhat less protection occurred when

the antiserum was administered 5 hours after the intracerebral injection of the organisms. An interval of $2\frac{1}{2}$ hours between the injection of antiserum and organisms was arbitrarily selected for the following experiments.

Effect of Complement upon Protection—The effect of complement upon the protective action of antisera was determined by comparison of 4 antisera in fresh and inactivated states and with the addition of guinea pig complement to the inactivated serum. The amount of complement arbitrarily chosen was 2 units as determined by hemolytic titration with a standard amboceptor. In this dose complement had no apparent effect upon the protective activity of inactivated serum. Furthermore, no significant difference in protective activity could be noted between fresh and inactivated antisera.

Mouse Protection Tests Using Intraperitoneal Injection of Antiserum and Intracerebral Injection of Organisms—In preliminary experiments using intraperitoneal injection of antiserum and intracerebral injection of organisms the following results have been obtained: An antiserum prepared against an organism of moderate virulence, 0901, and giving an H agglutinin titer of 1–2,560 and an O titer of 1–20,480, gave definite protection against 10 m.l.d. even in dilution of 1–100; whereas an antiserum against the same organism with an H titer of 1–80 and an O titer of 1–640 showed little significant protection.

No difference was observed in the protective action of two antisera prepared respectively from relatively avirulent and virulent organisms and having H agglutinin titers of 1–80 and 1–5,120 and O titers of 1–5,120 and 1–2,560. Both antisera protected against 2 m.l.d. of the test culture.

No conclusions can be drawn from these preliminary experiments. Further work is in progress.

SUMMARY

Intracerebral injection into mice is recommended for measurement of the relative virulence of strains of the typhoid bacillus. In our hands this method of injection has given more satisfactory results than the intraperitoneal route.

Intracerebral injection of organisms combined with intraperitoneal injection of antisera is suggested as a method for measuring the protective value of these sera against typhoid bacilli. The data so far obtained do not justify definite conclusions, but serve to indicate the feasibility of the technic and a possible correlation between virulence, H and O agglutinins, and protective activity of the antityphoid sera.

Dangers to Health of Uninterrupted Working Periods

THE medical committee of the German Society for Industrial Hygiene has set up "principles for regulating the hours of work and of recesses from the standpoint of health." These principles state that the uninterrupted working period is detrimental to health, and they reject it. They recommend the introduction of a divided working time

wherever the management of the establishment and the transportation permit it. They recommend a noon recess of 2 hours, so that the worker may be enabled to go to his home. When this is impossible there should be suitable recesses so that the workers may take a warm meal at their place of work at noon.—*Penn. M. J.* 38, 6:426 (Mar.), 1935.

A Semi-Automatic Bacteriological Dilution Bottle Filler

PAUL S. PRICKETT, PH.D.

Bacteriological Laboratory, Mead Johnson & Co., Evansville, Ind.

THIS apparatus* has been designed and in use for several years in the author's laboratory where it has invariably attracted the attention of visiting laboratory workers. Because of their enthusiasm and their frequent admonitions to publish a description of the apparatus, this note is offered in the hope that it may help to solve problems in other laboratories as well as it has in this one.

The photograph is largely self-explanatory. The filler is designed to fill two dilution bottles (A.P.H.A. type) simultaneously. A slightly modified design perhaps would be necessary for other types of dilution bottles. In use, a number of empty bottles are stood at the filler's right (the operator's left as he stands facing the filler), which is mounted in this laboratory on the drain-board of a sink. With his left hand the operator places two bottles at A while his right hand moves the valve-actuating lever B which sets the synchronized, two-way valves so as to fill the measuring cylinders C. When they are full, that is, containing the required amount of water, any excess overflows at D and is carried away by the drain E. As soon as the measuring cylinders C are full, the lever or valve handle B is moved to set the valves so that the supply is shut off and the measured volumes of water are dis-

charged through the nozzles F into the bottles. Immediately after the water runs into the bottles, the lever is moved back to the filling position and, while the measuring cylinders are refilling, the filled bottles are removed to the left of the filler, and two empty bottles put in place.

The water inlet, shown at G, may be connected with either the tap or a distilled water supply. Distilled water is used in the author's laboratory and consists of a 5 gallon bottle on an overhead shelf. The overflow from the drain can be collected and saved, if distilled water is used, or it can be run into the sink. It is our experience that with a little practice not enough water is wasted to pay to save it.

The set screws H hold movable sleeves J within the measuring cylinders C that are adjustable. Since these sleeves form the lip of the overflow the amount of water held and delivered by the measuring cylinders is governed by raising or lowering the sleeves.

In this laboratory 45 c.c., 90 c.c., and 99 c.c. dilution blanks are used extensively, hence the filler was made so that all three volumes are easily obtained. To obtain 45 c.c. dilution blanks the solid cylinders K are put in the measuring cylinders C to displace the necessary amount of water. The solid cylinders L are used in the same way to secure 90 c.c. dilution blanks, while to obtain 99 c.c. dilution blanks no displacement cylinders are used in

* Built by George Koch Sons, Evansville, Ind., who also aided in designing it.

the measuring cylinders. The filler is set to deliver a slight excess of water to each bottle to compensate for the water evaporated during sterilization.¹

The etched marks on the bottles, shown in the picture, are 45 c.c., 90 c.c., and 99 c.c. calibrations. *Standard Methods of Milk Analysis*² recommends a 99 c.c. calibration mark. Since we use large numbers of the three different water blanks we find it helpful to calibrate our bottles as it assures greater accuracy in the volumes of dilution water and also prevents confusion of the different dilution blanks.

Numerous tests and checks have

shown that this dilution bottle filler delivers accurate volumes of water. Being made of nickel plated brass and monel metal it does not corrode and its cost of upkeep has been nil. We previously filled our dilution blanks from a 100 c.c. burette equipped with a side arm attached to a distilled water supply. We find that we can fill dilution bottles as accurately and in one-fourth to one-fifth the time previously required.

Use of Toxoid Unprecipitated, Toxoid Precipitated and Toxin-Antitoxin Flocculi

WILLIAM H. PARK, M.D., F.A.P.H.A.

Director of Laboratories, New York, N. Y.

THE toxoid precipitate because of its very slight solubility is by far the most immunizing of the toxoid products. Its disadvantages are that it causes much greater local and constitutional reactions in older children and adults than does the toxoid-antitoxin flocculi and somewhat more than the same quantity of toxoid in the fluid form. Also when care is not taken to keep the amount of alum in the vaccine under 5/10 per cent, there is a tendency for the injection to produce an abscess. When the precipitate is concentrated it is apt to contain an excessive amount of alum. The federal regulations therefore require that the amount of salt solution with the precipitated toxoid should equal the original amount of broth.

Unprecipitated diphtheria toxoid either with or without the addition of 2/10 per cent alum is a much more efficient immunizing agent than toxin-antitoxin although much less than an equal number of units of the toxoid precipitate. Abscesses almost never follow the injections of toxoid in solution. When we consider the percentages of successful immunization in small groups of children, we should remember that the majority of them react readily in producing antitoxin from the injected toxoid, and of the minority only 2 to 5 per cent are much more resistant. Different groups of children necessarily

have different proportions of the more resistant children. For this reason when small groups are vaccinated a rather weak preparation may occasionally give as good or better figures than a strong one in another small group. We also realize that a month after immunization, fewer children have become Schick negative than at the end of 2 months, and, unless all have become negative by that time, than at the end of 3 or more months. One very important thing to consider is that it is the potency of the toxoid as well as the quantity of the fluid injected, which is of importance. The potency is determined by testing the number of antigenic units present which under most conditions can be considered the same as the flocculation units. Therefore, $\frac{1}{4}$ c.c. of one preparation may have all the antigenic value of 1 c.c. of another preparation. Until a year ago 10 or 15 antigenic units in 1 c.c. of toxoid solution were about the best that could be regularly made. If, therefore, the flocculation or antigenic units are not given, we have no way of knowing the immunizing value of the preparation except through the results obtained in immunizing children.

In closing, I want to give some statistics which bring out the fact that the majority of very young children are readily immunized by any fairly potent

preparation, and that there is an unknown minority in any given group who are more resistant. The first is a group of 269 children about equally divided in ages between the first 4 years of life. Of these, 269 received a single injection of $\frac{1}{2}$ c.c. of a 40 antigenic units per c.c. preparation. The 20 units of toxoid were in the form of the alum precipitate. At the end of 1 month 264 gave a negative Schick reaction and 7 remained positive, and at 2 months 268 gave negative and 1 a positive reaction, a percentage of success of 97.3 and 99.6. At the end of 1 month 66 per cent of the children still showed locally at the point of the deposit of the precipitate, gradually disappearing nodules some of which at first were from $\frac{1}{2}$ to 1 cm. in diameter. No abscesses developed.

As a contrast, I give the results of an early test using an alum precipitate containing but $8\frac{1}{2}$ flocculation units in each c.c. One hundred sixty-one children received a dose of 1 c.c. of this toxoid. At the end of 1 month 105 had become negative while 56 remained positive; at the end of 2 months 140 children gave negative Schick tests and 21 positive, and at the end of 3 months, all were negative. Here we see that a comparatively small amount of the toxoid precipitate gave 100 per cent of immunity at the end of 3 months but a large percentage had not changed in 1 month.

The results obtained from the use of a preparation of toxoid in the fluid form both with and without the addition of 0.2 per cent of alum. Two injections of 1 c.c. of a preparation of about 9 flocculation units given at intervals of 2 weeks, gave the following results at the end of a year. First a preparation having no alum added having about 500 school children injected, gave at the end of the year 93 per cent of negative tests. A second test was done with toxoid with 0.2 per cent of

alum added. In this case 95 per cent gave negative reactions at the end of a year. These tests were carried out by Dr. Volk of Pontiac, Mich., with toxoid made in this laboratory.

In another test of the fluid toxoid without alum, 71 small children aged from 9 months to 4 years were given a single injection of 1 c.c. of 40 flocculation units. At the end of 1 month 77.4 were negative; at 2 months 88.7, and at 3 months 90 per cent. This is a fairly average result.

The final preparation that I wish to speak of is the toxin-antitoxin flocculi. This as you know was developed by Dr. Povitzky in our laboratory. The flocculi formed by the union of a suitable amount of antitoxin to the toxoid are washed, resuspended, and heated to 80° for $\frac{1}{2}$ hour. This destroys the antitoxin but hardly affects the toxoid. In 42 nurses given an injection of a preparation containing over 40 flocculation units per dose, 78 per cent had developed a negative Schick test at the end of 1 month, and 94 per cent at the end of 3 months. Before we used the flocculi the nurses complained of the severe reactions, but not after we began to use the toxoid-antitoxin flocculi.

In New York City, at the present time we are using the toxoid precipitate in all children under 5, giving a single dose of 1 c.c. containing from 20 to 40 antigenic units. Undoubtedly doses of $\frac{1}{2}$ c.c. would give nearly the same results so far as the percentage of children becoming Schick negative is concerned; but the average amount of antitoxin developed in the children and its duration in them would of course be less. In the older children and adults we are giving a fluid toxoid either with or without $\frac{2}{10}$ per cent of alum or the precipitate. The first injection is $\frac{1}{10}$ c.c., the second injection given at an interval of either 2 or 4 weeks has from $\frac{1}{10}$ to 1 c.c., according to the

local reaction of the first dose. It seemed to us unwise to produce the occasional annoying but not otherwise harmful reaction which sometimes follows injections in school children of a first large dose as these disturb the parents. It seemed better to give a testing dose of a small amount to be followed according to the reaction by a larger or full dose. Even 1/10 c.c. of a good preparation contains about 3 antigenic units which is one-third the size of what was a full dose 1 year ago. We certainly have in these 3 preparations, suitable immunizing material for all infants, children and adults.

What Is Public Health?

IS not public health merely a matter of water supplies, ventilation, sewage, clinics, drains, street cleaning, garbage, infectious diseases, public health nurses, flies, dirt, slums, and serums? True it is that these items are all in it. But they no more constitute public health than mere paint, canvas, and brushes constitute art; or mere iron ore and smelters constitute architecture; or rods, lines, and nets constitute the fishing industry; or axes and wire rope constitute lumbering; or schoolhouses and textbooks constitute education. All these items are merely the tools of the arts. The tools of an art are essential to the art; but they do not constitute the art. Art is the result achieved; it is that object toward which tools merely perform the shaping of the path. . . .

That public health originated in the attempt to relieve crude physical suffering and especially to achieve this only by preventing disease, does not take

from its present or future immensely greater importance. That it has reached already its present outstanding influence is proof enough of its inherent strength, a strength derived wholly from its truth—that is, its correspondence with, not things just dreamed about, but things that are—not with just some things in the universe but with all things. . . .

The common objective of medicine and of public health is the reduction of human misery due to disease and death. The one devoted itself to the relief and cure of those already suffering, the other to prevention. Since neither fully succeeds, each must continue to supplement the other. Each in its own field has made enormous advances from each its own angle. Coöperation is increasing as each understands the other's problems better.—H. W. Hill, M.D. *California & West. Med.* 42, 2:139 (Feb.), 1935.

Diphtheria Studies II

Use of Intradermal Injections of Toxin-Toxoid Mixtures in Diphtheria Immunization *

WILLIAM EDWARD BUNNEY, PH.D.

*Associate Director, Bureau of Laboratories, Michigan Department of Health,
Lansing, Mich.*

THE purpose of this investigation has been to determine whether or not it would be possible to use an intradermal injection of a toxin-toxoid mixture for the dual purpose of immunizing and testing for immunity against diphtheria.

The ideal mixture would be one which functioned as a Schick test and at the same time always conferred immunity. This ideal has not yet been achieved, but some interesting immunologic observations have been made.

Several theories led us to study this problem. It seemed possible that the addition of a slight, standardized amount of the toxic principle to diphtheria toxoid might increase its antigenicity. The work of Ramon¹ with tapioca and calcium chloride, and of Glenny² with alum, suggests the possibility that part of the increased immunologic response to toxoid when these substances are added may be due to the local irritation which they induce. It seemed possible to us that the toxic effect of the free toxin might function similarly. Also the fact that it requires roughly 50 times as much toxin to pro-

duce a toxoid of antigenic value equal to a 0.1 L+ toxin-antitoxin mixture suggests that the greater efficiency of the toxin in the toxin-antitoxin mixture may in part be due to the free toxicity present. Another explanation for the increased immunologic response when tapioca, calcium chloride, or alum is used, is that they delay absorption of the toxoid, spreading its stimulus over a period of time and so in effect obtaining multiple stimuli with a single injection. Since absorption of material injected intradermally is known to be slower than that of material injected subcutaneously or intramuscularly it seemed that this slower absorption might increase the effectiveness of an intradermal injection. Finally, the work^{3,4} showing an increase in circulating antitoxin from repeated Schick tests gave added evidence of the possibilities in the study.

The first step was to determine whether toxoid could be made sufficiently formaldehyde-free to give a stabile mixture when added to toxin. The optimum concentration of toxoid also had to be determined and the efficacy of the mixtures established as accurately as possible on guinea pigs before human use.

* Read before the Laboratory Section of the American Public Health Association at the Sixty-third Annual Meeting at Pasadena, Calif., September 6, 1934.

12	21	8.4	0.5	" "	5

The work falls into 3 parts: (1) Study on guinea pigs to determine stability of the toxin-toxoid mixtures, and dosage and antigenicity. (2) Results in immunizing infants, children of school age, and adults. (3) Interpretation of the reaction in adults by comparison with the blood antitoxin content.

METHODS

The toxoid was purified by precipitation with alcohol and hydrochloric acid⁵ followed by solution in the borax-boric acid diluent of Glenny, Pope and Waddington.⁶

The mixtures of toxin and toxoid were diluted with 0.05 per cent protone⁷ solution containing 0.85 per cent NaCl and adjusted to pH 8.0. For preservative, merthiolate was added to make a 1-10,000 dilution. The final concentration of the toxin was always Schick strength (1/50 m.l.d. per 0.1 c.c.), only the toxoid concentration being varied in different preparations.

The method of drawing the bloods from adults and of titrating the serum has been described.⁸ Blood was drawn not more than 24 hours before doing the Schick test.

RESULTS AND DISCUSSION

Stability of toxin-toxoid mixtures and their antigenicity for guinea pigs:

Previous work⁹ substantiated the results of Glenny, Pope and Waddington⁵

in showing that if a toxin diluted to Schick strength is stable for 24 hours at 37.5° C., it will be stable for at least 6 months at room temperature. Using this method for comparing stability, toxin-toxoid mixtures with various concentrations of toxoid were tested as shown in Table I. To test the toxicity of the incubated preparations 5 c.c. (1 m.l.d. if it was a completely toxic Schick preparation) were injected subcutaneously into 250 gm. guinea pigs. If the pigs lived longer than 4 days the preparation was considered to be no longer completely toxic. It is interesting to note that 4.0 L_t's of purified toxoid per 0.1 c.c. contained sufficient stabilizing material to maintain the toxicity of the diluted toxin during 3 weeks of incubation when diluted in the borax-boric acid buffer of Glenny, Pope, and Waddington. For concentrations of 1.5 L_t's or less per 0.1 c.c., it seemed advisable to add 0.05 per cent protone in order to stabilize the toxin. The resulting preparations were remarkably stable with the three diphtheria toxin preparations tried, as shown in Table I. Evidently purification of the toxoid removed sufficient of the detoxifying formaldehyde used in preparation.

Having a stable preparation, our next concern was to investigate the comparative antigenicity in guinea pigs of subcutaneous and intradermal injections, and of toxic and non-toxic injec-

COMPARISON OF METHODS OF IMMUNIZATION

<i>Preparation</i>	<i>Lt's per 0.1 c.c.</i>	<i>Method of Administration</i>	<i>No. of Guinea Pigs Injected</i>	<i>Per Cent Surviving 5 m.l.d.'s 16 Days After Immunizing Injection</i>
Toxin-Toxoid Mixture No. 2	4.0	Subcutaneously	9	70
	4.0	Intradermally	10	90
Conc. Toxoid No. 29	4.0	Subcutaneously	8	40
	4.0	Intradermally	10	50

tions. Table II shows the results. Guinea pigs weighing from 275 to 350 gm. were used in each test. The results seem to indicate an advantage, in immunizing guinea pigs, of a toxic intradermal injection over a toxic or non-toxic subcutaneous injection containing identical amounts of toxoid.

We next determined the ability of the preparations to meet the requirements of the National Institute of Health antigenicity test for toxoids. This test requires that at least 8 of 10 pigs (weighing from 275 to 350 gm.) which have 6 weeks previously received a single injection of the toxoid must survive for 10 days after an injection of 5 m.l.d.'s of toxin. All the pigs were given a single 0.1 c.c. intradermal injection of the mixtures as shown in Table III. The survival of all the pigs encouraged us to try the preparations on humans.

Antigenicity of toxin-toxoid preparations for humans:

Preliminary study on volunteer medical students showed that the reactions from a preparation containing 4.0 Lt's per 0.1 c.c. were too severe. Like-

wise the reactions from preparations containing 1.5 Lt's per 0.1 c.c., although not serious, were too large to be satisfactory for Schick use. However, preparations containing 0.5 Lt per 0.1 c.c. seemed to give reactions in children, especially those of preschool age, which were satisfactory from the standpoint of size and lack of undesirable swelling or soreness.

In Table IV are compared several immunizing procedures in infants. The median age of this group was 2-4/12, the average, 2-5/12. All children positive at the end of 1 month received additional toxoid injections but the results are not used because of the possible antigenic effect of the Schick retest. It is interesting to note the quick response of those children receiving the intradermal injection of the toxin-toxoid mixture followed by concentrated toxoid given subcutaneously (Group 1). It seems likely that the 90 per cent immunity at the end of 1 month is not due solely to the concentrated toxoid since when only concentrated toxoid was given; all 4 remained positive (Group

3	10 L _t 's regular Toxoid with no pre-Schick.....	1 month	32	81
4	40 L _t 's conc. Toxoid with no pre-Schick.....	1 month	0	4

4). This last is too small a series to be conclusive but seems significant since only 4 of the 42 babies who also received the intradermal injection remained positive. The comparatively poor results with 2 doses of concentrated toxoid given to children of school age, shown in Table V (Group 2) is additional evidence that the intradermal injection was important in the quick response and the high percentage immunized.

The results in Table V indicate that in children of school age intradermal injections of toxin-toxoid mixtures increase the antigenic response. The first 2

The study of the value of intradermal injections of toxin-toxoid mixtures in immunization of the adult was made in 2 Michigan hospitals for the insane. In the first hospital a toxin-toxoid mixture containing 0.5 L_t per 0.1 c.c. was used, controlled with the heated control of a regular Schick preparation. The results as a Schick test were obviously not reliable since 82 per cent of the persons had positive reactions of whom 42 per cent had more than 0.03 unit of antitoxin per c.c. of serum.*

These false positive reactions bring up the question of the significance of the immunization figures in Tables IV

TABLE V

COMPARISON OF DIFFERENT IMMUNIZING PROCEDURES IN CHILDREN OF SCHOOL AGE

Group	Procedure	Interval Between Last Injection and Re-Schick	Per Cent Negative	Number in Group
1	0.1 c.c. = 1.5 L _t Toxin-Toxoid mixture followed by 30 L _t 's concentrated Toxoid in 1 week and another 30 L _t 's 2 weeks later.....	1 month	95	48
2	Schick test followed by 30 L _t 's concentrated Toxoid in 1 week and another 30 L _t 's 2 weeks later.....	1 month	64	229
3	0.1 c.c. = 0.5 L _t Toxin-Toxoid mixture intradermally	6 weeks	72	18

groups which received the subcutaneous concentrated toxoid were free-living urban children, those receiving only the intradermal injection of toxin-toxoid (Group 3) were inmates of a state hospital for the feeble-minded. These last are too few for the results to be conclusive, but their significance is augmented by the fact that to start with they were all Schick positive to a regular test given at the same time as the injection of the toxin-toxoid mixture. This regular Schick test may have increased the antigenic response.

and V. Of the infants receiving intradermal injections of toxin-toxoid mixtures containing 0.5 L_t per 0.1 c.c., 95 per cent gave positive reactions. However, comparison of the results in those with no pre-Schick test (Group 3) with those in the toxin-toxoid injected group (Group 1) show the figures to be significant, especially since of necessity the toxin-toxoid group contains fewer

* The 0.03 unit was chosen as the "Schick level" because, as shown,⁸ the study of the Schick reaction in adults indicated this to be a practical dividing point.

originally negative children, only the positive reactors being injected and studied. As to the first 2 groups in Table V, if the 48 children who originally had been positive to the toxin-toxoid mixture should have been only 30 per cent positive, the per cent immunized would be 85, still a significant increase over the 64 per cent immune with the regular Schick test. Therefore it seems that in both groups, regardless of the reliability of the reactions from the toxin-toxoid injections as Schick tests, the immunity results show a definite advantage in the use of the toxin-toxoid mixtures.

In an attempt to obtain a preparation that would function as a Schick test material in the adult, the content of the toxin-toxoid mixture was reduced to 0.25 L_t per 0.1 c.c. and a control mixture prepared which was identical in every respect except that the Schick toxin was heated to atoxicity. Controlled injections were given with these preparations to alternate individuals at the second hospital, the others receiving a regular Schick test and control. The

results are shown in Table VI. The close agreement in proportion of reactions was surprising.

A comparison of the effect of the injection of 0.5 L_t of toxoid equally divided between the Schick material and its control in different immunizing procedures is shown in Table VII. Evidently the toxin-toxoid mixture raised the antigenic response in each instance. The injection of only 0.5 L_t of toxoid plus 1/50 m.l.d. of toxin followed in 1 week by 5 L_t's of toxoid subcutaneously, was at least as good an immunizing procedure as 2 doses of 5 L_t's of toxoid alone given subcutaneously with an interval of 3 weeks. It would seem that 0.5 of an L_t of toxoid plus 1/50 m.l.d. of toxin as administered here in a toxin-toxoid mixture and control is at least as efficient an antigen for the initial stimulation in a 2 injection immunizing procedure as 10 times this amount of toxoid given subcutaneously. It seems possible that either the presence of the 1/50 m.l.d. of toxin or the use of an intradermal injection, or both, has increased the antigenic response.

The significance of the reactions caused by toxin-toxoid mixtures in adults:

Determination of the increase of circulating antitoxin resulting from the different antigenic stimuli gives an additional measure of the response to the intradermal toxin-toxoid injection. In Table VIII is analyzed the relationship between the antitoxin concentration before and after various antigenic stimuli. In Table IX is compared the average increase in antitoxin concentration in the toxin-toxoid procedure with the average increase when the regular

Schick test was used. A definitely larger increase in antitoxin follows the use of the toxin-toxoid mixture. The response as measured by antitoxin increase confirms the response as measured by the Schick test.

It seems noteworthy that the antitoxin response of the Schick negative individuals having less than 0.002 unit of antitoxin originally was far greater than that of the positive reactors with the same scarcity of antitoxin, and that the response of the pseudo reactors fell between these 2 groups (as shown in Table VIII). The fact that the nega-

INJECTION OF TOXIN-TOXOID MIXTURE

		Average	Final Antitoxin	Increase Factor Due to Toxin- Toxoid Mixture
			Original Antitoxin	
Original negatives	Regular Schick		248	
	Toxin-Toxoid mixture		571	2.3
Original positives 1 dose of Toxoid	Regular Schick		129	
	Toxin-Toxoid mixture		237	1.8
2 doses of Toxoid	Regular Schick		201	
	Toxin-Toxoid mixture		426	2.1
3 doses of Toxoid	Regular Schick		161	
	Toxin-Toxoid mixture		373	2.3

tive and pseudo reactors had the greater increase in antitoxin in spite of receiving the least amount of antigen gives further evidence, in addition to their Schick negativity, that their immunologic condition differs from that of Schick positive persons. It seems possible that the explanation for the antitoxin response of the pseudos being somewhat less than that of the negative reactors was that a portion of the pseudos were really combined reactors impossible to differentiate. These individuals would be expected to give the response of a Schick positive person and so lower the average increase of the pseudo group. It is interesting to note that in the negatives a considerable response to the regular Schick test was obtained but that the toxin-toxoid mixture gave a greater stimulus.

When we first considered using a toxin-toxoid mixture as Schick test material it seemed logical to expect that false-positive reactions would occur. We would expect this to result from neutralization of the antitoxin at the site of injection by the toxin and toxoid contained in the mixture, leaving some toxin free to damage the tissue, resulting in a positive reaction. At least a

50-fold increase of antitoxin combining power over that of a regular Schick test due to addition of 0.5 L₁ of toxoid made such a result seem likely. The high percentage of positive reactions from the inadequately controlled injections given in the first hospital mentioned seemed to bear out this theory. We were interested to note that this was not the case in the second hospital where more adequately controlled injections were given. Here there was not a significant increase in false positives (Table X) but only a large increase in the percentage of pseudo reactions, there being 37 per cent of these with the toxin-toxoid mixture as against 13 per cent with the regular Schick test. This group of pseudo reactors invites closer analysis. With the regular Schick test they would have been negative. When combined with the straight negatives as in Table VII the similarity of the percentages with those obtained on alternate individuals with the regular Schick test leaves little doubt of this, yet they are different immunologically. They have a sensitivity to the toxoid which is greater than that of the straight negative individuals and less than those who would be pseudo

TABLE X

COMPARISON OF REACTIONS TO TOXIN-TOXOID INJECTIONS WITH REGULAR SCHICK TEST AS TO DISCREPANCY BETWEEN SCHICK SIZE AND ANTITOXIN CONCENTRATION BEFORE ANTIGENIC STIMULATION

	Kind of Schick and Size of Reactions						Remarks	
	Neg.	Pseudo	Comb.	Positives *				
				1-2	1-3	1-4		Total
Toxin-Toxoid Reactions per cent with less than 0.03 unit...	15	17	59	60	81	100	83	364 persons in the series
Regular Schick Reaction per cent with less than 0.03 unit...	13	13	58	76	92	96	90	559 persons in the series

* The complete Schick reading was represented by two numbers, the first giving the size of the control, the second the size of the test. The symbols represented diameters as follows:

Symbol	Diameter in Millimeters
1	0-9
2	10-19
3	20-34
4	35-44
5	45+

Thus a 1-2 reaction represents a negative control and a 10-19 mm. reaction from the test injection.

reactors with the regular Schick test. According to these results they do not seem to be any more responsive, at least, to the injection of antigen than are the straight negative individuals. The pseudo reactors averaged a 445-fold increase in antitoxin as contrasted with a 571-fold increase for the straight negatives.

The age distribution of the pseudo reactors is shown in Table XI. The marked diminution in the percentage of pseudos in the oldest age group is of interest.

relation between Schick size and antitoxin content shown in these 4 small samples seems to us to be significant. Of course these results may be applicable only to the adult.

This adequately controlled toxin-toxoid mixture seemed to give promise of being a usable Schick test preparation. There were no objectionable reactions and the size of the reactions compared very well with those obtained with regular Schick test material, 67 per cent of the positive reactions being 1-3's with the toxin-toxoid mixture and

TABLE XI

RELATION BETWEEN AGE AND PSEUDO REACTIONS TO TOXIN-TOXOID MIXTURE AND CONTROL

Age Group	No. Persons in Each Age Group	No. of Pseudos	Per Cent of Pseudos Each Age Group	Corrected * Percentage Distribution of Pseudos
15-39	102	37	36.3	37
40-64	210	87	41.4	42
65-89	51	10	19.6	21

* Corrected for variations in size of groups

Is the size of the Schick test any indication of the amount of circulating antitoxin? The results in Table XII indicate that it is. The fact that a 1-2 Schick test is only a 60-70 per cent certain indication that the individual has less than 0.03 unit of antitoxin per c.c. of serum is interesting. This places a 1-2 Schick test in the same category as a combined reaction, which, as in a previous study,⁸ is about as likely to be associated with more than 0.03 unit as it is with less. The approximate cor-

65 per cent with the regular Schick test. It is interesting, however, that the toxin-toxoid mixture used in the first hospital, containing twice as much toxoid (0.5 L_r per 0.1 c.c.) did give undesirable swelling in some instances and too large reactions in many. The age distribution of the reactions with swelling is shown in Table XIII. They seem to parallel the distribution of the pseudo reactions from the controlled preparation containing half as much toxoid in the injection. Here again the oldest

TABLE XII

COMPARISON OF ANTITOXIN CONCENTRATION WITH SIZE OF POSITIVE SCHICK TESTS

	Size of Positives				Total Number in Analysis
	1-2	1-3	1-4	1-5	
Before antigenic stimulation					
P.S.H. and T.C.S.H. pos. to regular Schick tests— per cent under 0.03 unit.....	76	92	96	90	200
P.S.H. pos. to Toxin-Toxoid mixture—per cent under 0.03 unit	60	81	100	100	91
After antigenic stimulation					
P.S.H. pos. to regular Schick test—per cent under 0.03 unit	60	95	100	...	30
T.C.S.H. pos. to regular Schick test—per cent under 0.03 unit	57	100	100	100	29

NOTE: P.S.H. and T.C.S.H. refer to Pontiac and Traverse City State Hospitals respectively.

TABLE XIII

RELATION OF AGE TO REACTIONS WITH SWELLING FROM INTRADERMAL INJECTION OF TOXIN-TOXOID MIXTURES CONTAINING 0.5 L_t PER 0.1 C.C.

Age	No. of Persons in Each Age Group	Reactors in Each Age Group	Per Cent of Each Age Group Reacting	Corrected * Per Cent of Reactors in Each Age Group
15-39	65	18	27.7	44.8
45-64	101	25	25.0	40.4
65-89	33	3	9.1	14.8

* Corrected for variation in size of groups

age group is the least likely to give the sensitivity reaction. How nearly comparable as to age are the groups from the two hospitals is shown by the fact that in one the mean age was 47.6 and the median 46, while in the other the mean was 47.5 and the median 46.

A preliminary study such as this can do little more than determine whether the results merit further investigation. It seems to us that they do. Even if a "single injection" antigen is developed which immunizes 95 per cent of those injected, it will still be desirable to do a Schick re-test as a check on the product used and for the sake of the 5 per cent still susceptible. If this Schick re-test would not only determine the susceptible 5 per cent but would also immunize them it would be valuable.

Although we realize that the important group for immunization is that of preschool age, in which group a pre-Schick is perhaps a waste of time, nevertheless considerable immunization of older children will have to be done for some time to come. The increasing of the circulating antitoxin of the Schick negatives in this group by the use of a toxin-toxoid mixture for the pre-Schick test seems logical, and an increase in the percentage immunized of those subsequently injected with toxoid certainly would be desirable. Another argument for the use of such a preparation is in clinic work. The child who comes for the Schick test and fails to return for a reading and immunizing treatment will have received considerable antigenic stimulation nevertheless.

The comment of those who carried out the study on babies is interesting. They observed no objectionable reactions but preferred to use the toxin-toxoid mixture because on children whose return was delayed for from 10 days to 2 weeks the reactions could still be read.

One of the promising points about the effect of intradermal injection of toxin-toxoid mixtures is the speed with which immunity is attained. The results with preschool children Schick tested 1 month after treatment we feel to be distinctly encouraging.

A final possible advantage to the use of toxin-toxoid mixtures such as described here is that in addition to functioning as an antigen and a Schick test they might serve as a toxoid reaction test as well. This possibility deserves further study.

SUMMARY

The properties of mixtures containing diphtheria toxin diluted to Schick strength in a diluent containing purified toxoid in various concentrations were studied. The following observations were made:

1. Tests on guinea pigs showed that mixtures containing as little as 0.5 L_t per 0.1 c.c. were stable for at least 7 days' incubation at 37.5° C. if 0.05 per cent protone was present in the mixture.

2. Tests for antigenicity on guinea pigs demonstrated that a mixture containing 0.5 L_t per 0.1 c.c. can meet the requirements of the National Institute of Health test for the antigenicity of toxoids if the 0.1 c.c. injection is given intradermally.

3. Studies on immunization of children of preschool age, of children of school age, or of adults, showed that the use of an intradermal injection of a toxin-toxoid mixture in place of the pre-Schick test increased the percentage immunized to Schick negativity by any of the procedures tried.

4. A comparison in adults of the reactions from an intradermal injection of a toxin-toxoid mixture containing 0.25 L_t per 0.1 c.c. with the antitoxin in the blood showed:

a. When a control injection was used with material identical except that the toxin was heated to atoxicity, the reactions were as satisfactory indicators of the blood antitoxin in adults as those from the regular Schick test.

b. The only difference from the regular Schick reactions was an increase in the percentage of pseudo reactions.

c. The effect of the intradermal injections of the toxin-toxoid mixture on immunization to Schick negativity was confirmed by the increase in the blood antitoxin.

5. The age group 65-89 contained a definitely smaller proportion of pseudo reactors to the controlled toxin-toxoid mixture injections than did the age groups 15-39 and 40-64.

NOTE: Our thanks are due:

Dr. C. C. Young for the preliminary tests on medical students.

Drs. Charles F. Church and Rae V. Nicholas of the Department for Prevention of Disease, Children's Hospital of Philadelphia, for the studies on infants of preschool age.

Dr. Edmund A. Christian, Medical Superintendent of Pontiac State Hospital and Dr. R. Phillip Sheets, Medical Superintendent of Traverse City State Hospital, for their coöperation and assistance in the studies on adults.

Dr. John D. Monroe and Dr. V. K. Volk of the Oakland County Department of Health, Pontiac, Michigan, for the studies on free living children of school age.

Minna Crooks, G. D. Cummings, and F. C. Forsbeck for assistance in the studies on adults.

J. W. Glassen, H. C. Hollon, H. Kibbe, and A. W. Tallman for assistance in the blood titrations in the studies on adults.

The 1934 Health Conservation Contests

THE Awards for the sixth annual City Health Conservation Contest and for the first Rural Health Conservation Contest were announced by the Chamber of Commerce of the United States at its Annual Meeting in Washington on April 29. Both Contests are conducted by the Chamber of Commerce of the United States in coöperation with the American Public Health Association. The Contest for cities is financed by a group of insurance companies and one philanthropic organization. It is open to any city anywhere in the United States, provided it has a local chamber of commerce or similar organization having affiliation with the Chamber of Commerce of the United States.

The Contest for counties or districts is supported by the W. K. Kellogg Foundation of Battle Creek, Mich. It is open to any county or district with full-time health service, provided it has a local chamber of commerce or similar organization having affiliation with the Chamber of Commerce of the United States.

Together the Contests had enrollment in 1934 from 45 states, the Islands of Hawaii, and Alaska. In all, 214 cities and 104 counties or health districts were entered embracing a population of between 29 and 30 million people.

The City Contest is in effect 6 contests, 1 for each of 6 population groups ranging from cities of over 500,000 population to those of under 20,000 population. One first award and as many honorable mentions as scores justify are given in each group. In the City Contest, there is also a Special Group composed of cities which have twice won the Contest in their respec-

tive population groups and have for this reason been excluded from the contest proper. Special Awards were given to those of this group which maintained their previous high standards during 1934. For 1934, there were 35 awards in the Contest proper and 5 special awards.

For purposes of the Rural Contest the country has been divided into 6 geographical areas, 3 east and 3 west of the Mississippi. These are:

Northeastern: Connecticut, Illinois, Indiana, Maine, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Ohio, Pennsylvania, Rhode Island, Vermont and Wisconsin.

Eastern: Delaware, Kentucky, Maryland, North Carolina, Tennessee, Virginia and West Virginia.

Southeastern: Alabama, Florida, Georgia, Mississippi, and South Carolina.

North Central: Colorado, Iowa, Kansas, Minnesota, Missouri, Montana, Nebraska, North Dakota, South Dakota and Wyoming.

South Central: Arkansas, Louisiana, New Mexico, Oklahoma and Texas.

Western: Arizona, California, Idaho, Nevada, Oregon, Utah and Washington.

One first prize and as many honorable mention awards as scores justify are given in each geographical division.

CITY CONTEST AWARDS

The awards for the 1934 City Health Conservation Contest are:

For the largest cities of *over 500,000* population, the first award goes to Baltimore, Md., and honorable mention to Buffalo, N. Y.

In cities of *between 250,000 and 500,000* population, Newark, N. J., attains the first award, and honorable mention goes to Minneapolis, Minn., Toledo, Ohio, and Dallas, Tex.

In cities *between 100,000 and 250,-*

000 population, Honolulu, Hawaii, wins first place, and honorable mention goes to Hartford, Conn., Grand Rapids, Mich., Springfield, Mass., Duluth, Minn., Yonkers, N. Y., Reading, Pa., and Utica, N. Y.

In cities of between 50,000 and 100,000 population, Pasadena, Calif., receives the first award, and honorable mention goes to Kalamazoo, Mich., Schenectady, N. Y., Evanston, Ill., Waterbury, Conn., Sacramento, Calif., Binghamton, N. Y., San José, Calif., New Rochelle, N. Y., and Greensboro, N. C.

In cities of between 20,000 and 50,000 population, the winner is Hackensack, N. J., and honorable mention goes to Watertown, N. Y., Pittsfield, Mass., Auburn, N. Y., Greenwich, Conn., and Santa Barbara, Calif.

In cities under 20,000 population, Palo Alto, Calif., obtains the first prize, and honorable mention goes to Englewood, N. J., Cliffside Park, N. J., Hibbing, Minn., and Miami Beach, Fla.

Special Awards were granted to Brookline, Mass., Detroit, Mich., Milwaukee, Wis., New Haven, Conn., and Syracuse, N. Y.

RURAL CONTEST AWARDS

The awards for the 1934, the first Rural Health Conservation Contest, are as follows:

In the *Northeastern Division* two first places are awarded to Cattaraugus Co., N. Y., and Westchester Co., N. Y.; honorable mention goes to Columbia County, N. Y., Barry Co., Mich., Southern Berkshire District, Mass., Allegan Co., Mich., and Eaton Co., Mich.

In the *Eastern Division* first place goes to Kent County, Md., and honorable mention to Davidson Co., Tenn., Ohio Co., W. Va., Rutherford Co., Tenn., Washington Co., Md., Forsyth Co., N. C., and Sullivan Co., Tenn.

In the *Southeastern Division* first

prize is won by Glynn Co., Ga., and honorable mention goes to Charleston Co., S. C., Lauderdale Co., Miss., Pike Co., Miss., and Leon Co., Fla.

In the *North Central Division* first place is awarded to Woodbury Co., Iowa, and honorable mention to Lyon Co., Kans.

In the *South Central Division*, the winner is El Paso Co., Tex.

In the *Western Division* first prize is awarded to San Joaquin Health District, Calif., and honorable mention is attained by Los Angeles Co., Calif., Santa Barbara Co., Calif., Spokane Co., Wash., and Yakima Co., Wash.

SIXTY-EIGHT AWARDS GIVEN

Between the City Contest, the Special Awards, and the Rural Contest, there were 68 awards given. In all 25 states were represented in these awards. New York led all the states with 12 awards; California came next with 8; followed by Michigan with 6. Connecticut, Massachusetts, and New Jersey had 4 each; and Maryland, Minnesota, and Tennessee had 3 each. Two awards each went to Florida, Mississippi, North Carolina, Texas, and Washington. Georgia, Hawaii, Iowa, Illinois, Kansas, New Mexico, Ohio, South Carolina, Pennsylvania, West Virginia, and Wisconsin each received one award.

Including the Special Awards for cities which had won the City Contest twice, there were 17 first prizes. Among the first awards, California led with 3, followed by Maryland, New Jersey, and New York with 2 each. Georgia, Hawaii, Iowa, Massachusetts, Michigan, Connecticut, Texas, and Wisconsin each received 1 first prize.

FREE HEALTH SURVEYS

The purpose of these Contests is to promote basically sound public health work in this country to the end that untimely and premature deaths shall be

eliminated and economic losses from unnecessary illness reduced to a minimum. It is hoped that Contests will accomplish this purpose by enlisting the active intelligent interest of business men in the value of public health as an asset and by stimulating a more unified and better coördinated program on the part of the various groups and organizations interested or engaged in the protection and promotion of the public health.

It is believed that every unit city or county entered on the Contests derives benefit from its participation whether it wins or even attains a high score. The Contests assist every participant in that:

1. They provide an opportunity for a self-appraisal of the community's public health program.

2. The backing and intelligent interest of a well formulated Public Health Committee of the Chamber of Commerce results in increased public health interest and knowledge of sound public health work.

3. The fact that these are community-wide rather than health department contests is conducive to obtaining a more complete picture of public health facilities and programs than might otherwise be obtained.

4. The incentive of the Contests being a competition in which all interested organizations and groups participate, generally results in a more unified community interest and, therefore, in a better coördination and integration of the work of the various groups interested and engaged in public health work.

5. They foster a spirit of coöperation between the public health workers and the medical and dental professions in that specific credit is given for preventive work done by private physicians and dentists.

6. The Contests provide useful publicity in that the results of the analysis of the information submitted call attention to the strong features of the community's public health program and likewise point out its apparent needs. (These analyses are sent only to the health officers and chambers of commerce secretaries, and any public use of these is made by them.)

That the Health Conservation Contests are thought of real value by outstanding people in the field of public health is attested to by the following comments:

Dr. W. S. Rankin, a Director of the Duke Foundation and former Commissioner of Health of the State of North Carolina said: "It is my opinion that these annual health conservation contests have already done more to promote basically sound public health work in this country than anything which has happened during the past decade."

T. F. Cunneen, Manager of the Insurance Department of the Chamber of Commerce of the United States, said: "It is particularly gratifying to realize that over 3,000 business men have, through these contests, become actively identified in promoting public health protection as a business and economic asset. This important interest should prove of ever-increasing value to the future health of our people. Insurance companies recognizing the value of sound health promotion have been largely responsible for the financing of the city contests."

Dr. A. J. Chesley, Commissioner of Health of the State of Minnesota, said: "These health contests provide the most effective means available anywhere for bringing public health problems and the need for their solution forcibly to public attention, particularly locally."

Dr. C.-E. A. Winslow, Professor of Public Health at Yale, said: "A very significant index that the health conservation contests are accomplishing their purpose is the fact that over 90 per cent of all those cities competing for two or more years have shown appreciable advances in their public health practices and records."

THE MALARIA EPIDEMIC IN CEYLON

DURING several months there have been repeated notices in the daily press of an epidemic of malaria in Ceylon of unusual severity. It has also been commented on in a number of scientific journals. Recently what appear to be reliable reports have reached us.¹

No authentic information of the number of deaths from malaria during this epidemic is available, though it is believed that from November, 1934, to January, 1935, more than 30,000 have occurred. In January, 1935, 5,468 of the 7,038 victims were children under 14. In about two-thirds of the area of the Island, conditions are favorable to the breeding of anopheles. Here the endemicity is high and the spleen rate runs from 40 to 60 per cent, and even rates of 80-90 per cent occur. There is considerable relative immunity, and epidemics of malaria do not occur. In the healthful part of the Island, about one-third of the area, the rains failed to supply the usual amount of water, which varies from 100 to 200 inches a year, giving an abundant flow which flushes the channels and prevents the formation of quiet pools favorable for mosquito breeding. In 1933, the rains failed, leaving many pools suitable for the development of mosquitoes in the beds of streams in the healthful third of the island. The inhabitants, having very little acquired immunity, became an easy prey to the malaria carrying mosquito, *Anopheles culicifacies*. This hitherto healthy area has felt the full force of the epidemic.

The death rate is rather hard to understand, since it is stated, on the basis of earlier surveys, that 57 per cent of the cases are benign tertian, 33 per cent quartan, and 10 per cent malignant tertian.

The failure of the rains already mentioned produced a drought which greatly reduced the food supply, and undernourishment was quite widespread; in fact, many of the population were on the verge of starvation. In India it is known

that famine almost invariably predisposes to epidemic conditions, so much so that in the Punjab and in Bengal, climatic conditions which are known to precede a famine usually are used by malariologists as an indicator in selecting the areas in which quinine treatment should be concentrated.

In spite of the high morbidity and high mortality there does not seem to be anything remarkable when judged by the standards of that part of the world. Epidemic outbreaks in India are usually accompanied by a fatality of 20 to 35 per cent. The area of Ceylon in which the epidemic is said to have been worst, has a population of approximately $3\frac{1}{2}$ million. There have been 500,000 cases, with 60,000 deaths, a fatality rate of 12 per cent, which is lower than one might expect. The normal fatality rate in India is 5 per cent, and therefore there seems no good reason for the excitement which the present outbreak has occasioned.

It has been suggested that a new type of the malarial parasite has been responsible. The daily press has spoken of "green germ" malaria, and *Science News Letter*, for February 16, 1935, has commented upon this. There does not seem to be any good ground for this supposition; certainly none, if the figures collected for the three known types of malaria can be accepted, as it at present seems they should be.

There is a lesson for us, however, in this outbreak. In spite of recent supposedly authentic statements to the contrary,³ malaria is very far from having been banished from our own country, much less from the world in general. For approximately 70 years the trend in the United States has been downward, with some fluctuations. During the summer of 1934, there was a very sharp rise with reinvasions of portions of territory formerly malarious but which were believed to have been cleaned up. In these areas an increase of virulence was noticed following the rule of most contagious diseases when invading new territory. In 1934 the rate reached a higher stage than at any time during the last 20 years, and appeared in 3 states which have been at the northern limits of endemic malaria, and in one which has been outside of the malaria district for 10 years. Indeed, in one instance an outbreak occurred in a northern state where malaria had never been reported before.⁴ It is for these reasons that the work of the CWA in ditching and drainage have been of such value to the country.

TUBERCULOUS INFECTION OF NURSES AND MEDICAL STUDENTS

IN spite of the fact that many of our universities and schools now have organized health services and require a physical examination of students before entrance, tuberculosis still takes its toll, and the evidence seems fairly clear that quite a number of students are infected during attendance. This is especially true of medical schools and schools for nursing. A review of the matter, especially in regard to nurses, is given by the *J.A.M.A.*,¹ from which we take a number of facts.

In 1933, Heimbeck, of Oslo, gave the result of several years of observation in the Ulleval Hospital. On entrance, approximately 50 per cent of the girls who

entered as probationers were negative to the tuberculin test, but before graduation all reacted positively, demonstrating that infection had occurred during their duties. Heimbeck was able to observe the time when the negative reactors became positive. An attempt was made to determine the focus of infection, though in the majority of cases it escaped detection, while in others it was in the lung. Some cases were evidently reinfection, the students having gone through their preliminary manifestations before they entered the hospital.

In St. Paul, Geer showed that from 60 to 75 per cent of the probationers in the Ancker Hospital had not been infected on entrance, but all reacted positively to tuberculin after a tuberculosis service and before graduation. In approximately 5 per cent, pleurisy with effusion occurred or other lesions were demonstrated.

In 1934, Myers, Diehl, and Lees showed that of the probationers in hospitals in Minneapolis, from 13 to 40 per cent react positively to tuberculin, while in those hospitals which require tuberculosis service, approximately 100 per cent react positively during the senior year. In other schools where there is no tuberculosis service and only occasional cases of the disease are admitted, there is still a definite increase in the incidence of positive reactors among the nurses, but it is not nearly so marked as in those schools in which tuberculosis nursing is required. A comparison of schools of nursing with schools of education showed that in the latter only 23 per cent of the entering students reacted positively, whereas after 4 years there had been only a 4 per cent increase in the positive reactors. In other words, 27 per cent reacted positively to tuberculin on graduation in the school of education against 100 per cent in the school of nursing.

In 1933, Shipman and Davis published their results after nearly 10 years of observation among students of nursing. They found that between 6 and 7 per cent of the students at the University of California Hospital developed clinical tuberculosis during training, while an additional 4 per cent developed the disease between graduation and the time the study was reported. The majority of nurses who reacted negatively as probationists remained negative through training, a fact which they attribute to the very small number of tuberculous patients in the hospital.

In 1930, Ross demonstrated that about 6 per cent of the nurses in Manitoba fell ill with tuberculosis during their training or within a year after graduation, and this figure is much greater than the proportion in which women in the Province in general, or any other class, show tuberculosis.

In New Zealand, Jones has shown that approximately 3 per cent of the girls in training fall ill each year. In teacher training colleges he found very little tuberculosis and concluded that girls from 19 to 25 remain in excellent health when subjected to healthful conditions, but when exposed to cases of tuberculosis, all became positive reactors to tuberculin and 3 per cent developed tuberculosis.

In Saskatchewan, Ferguson has shown that the incidence of tuberculosis among nurses in training is 12 times that found among the general population and 8 times that found among normal school students of approximately the same age.

A study² covering 8 years, during which 300 medical students and 380 nurses at the Boucicault Hospital were examined with the idea of weeding out the unfit as early as possible, showed that among the 300 students there was only 1 case of pulmonary tuberculosis with bacilli in the sputum, while 5 others showed unmistakable signs of having had pleurisy, and 6 others showed radiological

abnormalities some of which proved to be tuberculous. The 380 nurses had already undergone a comb-out but in spite of that, 1 case of pulmonary tuberculosis with bacilli in the sputum, and 1 of old pleurisy were found, while 6 other nurses showed some abnormality of the lung. The authors have been struck by the development of tuberculosis in persons who seemed perfectly well at the first examination. Suspecting that they were primary infections, during the last 2 years they included tuberculin skin tests in their routine examinations. Among the students 37 of 48, and among the nurses 161 of 205 gave positive reactions. Most of the negative reactors were town dwellers, and only 2 students and 10 nurses who were negative had homes in the country. In the course of the following 8 months, 7 of 9 negative reactors became positive and 4 of them showed other signs of tuberculosis. The authors wondered how these results could be correlated with those of Hamburger and Monti in Vienna, where 94 per cent of the children between 11 and 14 gave positive reactions. They believe that it was due to differences in the surroundings and to the effect of the antituberculosis measures at present. They concluded that their results prove that primary infections of young adults is common and that the onset may be sudden and even violent.

In commenting on this paper, Bezançon held that these observations tended to refute the idea that tuberculosis is a hereditary disease, an idea which, in France at least, seems to be again coming into fashion.

The review¹ referred to goes into the difference between first infection and reinfection to a considerable extent, and points out that the type of tuberculosis seen among the student nurses belongs to that formerly prevalent among children, but owing to antituberculosis measures, is now escaped by many who reach adult life free from tuberculous infection. When later they become infected, as many students of nursing do, the result is very much the same as that shown in childhood during the first infection. A curious result in a number of cases is the development of erythema nodosum, which is now regarded as an allergic manifestation which should always lead to looking for a tuberculous first infection type. In the majority of such cases there is no external manifestation except the positive reaction. Only recently has the close association between this condition and the first infection type of tuberculosis been recognized. It is probably due to a high degree of allergy.

After the first infection type of tuberculosis has produced an allergic reaction there is no way of determining how much additional infection occurs. It may be concluded therefore that if all the uncontaminated students become infected during training those who are already contaminated when they enter are reinfected. Tubercle bacilli are not rapidly destroyed in the body and may survive over long periods and eventually produce tuberculosis which becomes evident years after graduation. Shipman and Davis state that most of the nurses who developed clinical tuberculosis during training reacted positively on entrance.

After many pathological examinations, Sweany suggests that nature may defeat her purpose when she encapsulates bacilli and in later years reabsorbs the capsule, setting the tubercle bacilli free. This seems a fair explanation of some cases of tuberculosis in which the immediate origin is not clear.

To all of those who believe, as many have done and still do, that practically all tuberculous infection takes place in childhood, these recent studies give pause. However, they have brought about good results in that a greater number of examinations are being made and that more care is taken of students in our

schools. The study of Myers running over a number of years in which cases have been followed from childhood infection to adult tuberculosis are extremely suggestive. His results give a negative answer to our ideas that early tuberculous infection has a vaccinating effect and protects against adult tuberculosis.

-

SIXTH ANNUAL MEETING, WESTERN BRANCH A.P.H.A. HELENA, MONT., JULY 1-3

AT the Sixth Annual Meeting of the Western Branch of the American Public Health Association, public health matters of special interest to the West will be discussed, and a program of unusual value is being arranged by Dr. W. F. Cogswell, State Health Officer of Montana, President-Elect of the Western Branch, and Chairman of the Committee on Meetings and Publications.

Public health problems among western Indians; peculiarities of western water and sewage disposal systems; new plans for public health developments by the federal government; latest advances in the control of Rocky Mountain spotted fever, undulant fever, tularemia, silicosis, psittacosis; home nursing of communicable diseases; various aspects of tuberculosis; and modern advances in health education are among the subjects to be discussed. Among the distinguished guests expected are Katherine Lenroot, U. S. Children's Bureau; Josephine Roche, Third Assistant Secretary of the Treasury; Dr. Thomas R. Crowder, Chief Surgeon of the Pullman Company; Dr. A. J. Chesley, State Health Officer of Minnesota; Dr. Thomas A. Parran, Health Commissioner of New York; Dr. E. L. Bishop, Medical Director of the Tennessee Valley Authority; Helen LaMalle, Superintendent of Nursing, Metropolitan Life Insurance Company, New York City; and others.

The meeting will be held in conjunction with the annual meeting of the Montana State Medical Association.

W. P. S.

THE OPEN FORUM

REGINALD M. ATWATER, M.D.

Executive Secretary, American Public Health Association

THROUGH the courtesy of the Editor of the *Journal* and the Chairman of the Committee on Meetings and Publications, this space has been set aside for the use of the Executive Secretary. Dr. Atwater intends from time to time to communicate with the membership through this page and to bring to their attention affairs which are of importance to the professional public health workers of North America.

It is also intended that questions of general interest, from among the many received by the Association office, will be answered through these columns, and opportunity afforded for the expression of opinion pro and con among the readers of the *Journal*. The Executive Secretary will welcome suggestions of timely subjects for discussion here and will make use of the wide and distinguished membership of the Association for counsel in connection with the Forum material.

THE SOCIAL SECURITY BILL

ARE you familiar with the provisions of the Bill as now before the House of Representatives (H.R. 7260)? This bill differs in several respects from previous drafts, and it is worth study. The provision for unemployment and for old age security represent very substantial efforts in these directions. They provide for this load to be undertaken gradually by the public, and eventually to be shared by the employer and employee on a basis which is said to be sound from the actuarial viewpoint and in line with the opinions of many

advocates of these social safeguards who have studied the subject for years.

It is encouraging to note that the provisions for expansion of the federal public health service, for aid to states in maternal and child health and for crippled children are among the portions of the Bill toward which Congress at this time seems most favorably inclined. There are signs which indicate that the principle of federal aid to states for these purposes is now rather well accepted.

Although it remains to be seen whether this Social Security Bill can pass in its omnibus form at the present session, there are many indications that a new attitude toward federal responsibility is abroad, and it is well to think through the implications of this Bill for each locality so that, if it does become effective, adequate local provisions may be already under way.

MEASLES PREVENTION

THERE has come to the attention of the Executive Secretary a chart published in 1935 by the Michigan State Department of Health on measles prevention. Believing that many health officers will welcome such a clear and simple illustration of a rather complex affair, the chart is republished herewith by kind permission of Dr. C. C. Young.

If parental blood or immune serum is to be useful in actually reducing measles mortality, experience indicates that the practising physician needs encouragement and information on the technic of administration. The use-

USUAL COURSE OF MEASLES

fulness of such immune serum is greatly affected by the time at which it is given. The chart has been designed to make it easy for the busy practitioner to choose a date for this procedure so that it will be most useful to the child whom he desires to protect.

In view of the limited effectiveness of all our measles measures, is it not incumbent on health officers to make the really dependable procedures as simple and clear for the physician as possible?

HEALTH OFFICERS' INSTITUTE

THE suggestion has been made that at some future Annual Meeting there should be set up an Institute for Health Officers at which some competent instruction may be offered on such matters as planning the program, making up the budget, selecting personnel, and balancing the effort most intelligently—matters of great importance to all health officers, and especially to young workers in the field

who may profit by the accumulated experience of those who know how.

A somewhat similar Institute has been held for several years for workers in health education, and those who attend the three day sessions preceding the Annual Meeting can testify to the value of the Health Education Institute. What do you think? Do you recommend this matter for consideration by the Health Officers Section? If there is sentiment in favor, it may be discussed in this space again.

EPIGRAMS

WHAT are your favorite epigrams on health? Believing that there is room for more and that a collection of good quotations would be helpful to many workers in the field, it is intended to carry such epigrams in this column. Send in your own list.

"In nothing do men more nearly approach the gods than in giving health to mankind."—Cicero

PUBLIC HEALTH EDUCATION *

We Are Corrected—Most important is a letter from Norah March, editor of *Mother and Child*, London, which periodical was quoted in the April issue, under "Flamboyant and Not Polite" (page 490) as seeming to be critical of health education methods in the United States. Miss March says:

May we protest that we do not wish to express dislike of Public Health Education methods in the United States, but rather admiration! I only wish we could apply them here!

The American Dietetic Assn., mentioned under "Exhibit of Food Fads and Fallacies" (page 492), should now be addressed at 185 N. Wabash Ave., Chicago, Ill.

Education By Radio, as issued, will be sent free by National Committee on Education By Radio, 1201 16th St., Washington, D. C. (under "Radio," page 495).

Illinois Dept. of Public Health, Springfield, will be glad to supply copies of radio talks (under "Radio," page 496).

Motion Pictures at Milwaukee—It is probable that the space at Milwaukee will enable us to show health pictures. What have you in 16 mm.?

Syphilis Is News in New York State—Back in December Horace H. Hughes of State Committee on Tuberculosis and Public Health, S.C.A.A., New York, N. Y., prepared an office memorandum from which we quote:

The newspapers in New York State are beginning to shoulder their responsibility for the publication of news about syphilis control. During the past year our State Committee has a record of 50 papers which have printed one or more stories using either the word "syphilis," or venereal disease. In some of these papers, such as the *Utica Press*, and the *Syracuse Post-Standard*, the word "syphilis" has been printed in their headlines and as captions for photographs.

A large number of papers in the above list published only the story regarding Dr. Parran's resignation from the Public Health Committee of the National Advisory Council on Radio in Education, following the barring of a radio talk which he was scheduled to make, unless he removed all mention of syphilis from the manuscript. This is proof that if the syphilis news can be made emphatic enough and yet handled in a discreet manner, there is no reason why it should not be published by a great majority of papers in the state.

During the past 2 weeks I wrote to our executive secretaries in Niagara, Oneida, Onondaga, and Schenectady Counties and to Paul Benjamin in Buffalo—these are the places where the newspapers have not been averse to regular publication of syphilis news. I asked them to find out if their local editors had received any complaints from the readers of these newspapers on the publication of syphilis news. Replies have been received from all but Mr. Benjamin and all report that no objections have been recorded.

I also inquired from Mr. Greenman in Rochester whether there had been any objections from listeners-in over Station WHAM where a broadcast was made by Dr. Joseph Earle Moore on "Syphilis in Marriage." The reply again was negative.

These facts are conclusive evidence that the public is not greatly shocked or perturbed over the publication of this type of material. Editors and radio program directors have steadily maintained that such was the case.

I am, therefore, convinced that when the editors of the state are fully acquainted with the facts about the menace of syphilis, with the need for calling this menace to the attention of the people, we can break down among the newspapers, the so-called "conspiracy of silence."

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

Do They Mention Syphilis?—Do newspapers in your state or city ever mention syphilis or venereal diseases? Do broadcasting stations allow mention of the same?

Good use can be made of any information you may send to the editor of this department. Please send all clippings or specific information. If your information is incomplete please check details and send them as early as possible.

In April, 1935, *Journal*—This issue contained various references to health education.

In "Clinical Amebiasis in Relation to Public Health" (page 403):

The old struggle to develop a sanitary sense in the general public must go along with the education of physicians. A popular demand for clean food, clean dishes and utensils, clean kitchens, clean waiters and other food handlers, safe water supplies, absence of flies and insects where food is handled, clean hands and fingers, and the availability and enforced use of sanitary toilets and wash-bowls—such a demand would go far to control the amebiasis problem and with it many other related problems. . . .

This program should consist of (1) education of physicians, (2) education of the public. . . .

In "Potential Problems of Industrial Hygiene in a Typical Industrial Area" (page 423):

In order to acquaint industry, the medical profession, and others interested in such a program, it may be necessary that the personnel carry on an educational campaign, designed to instruct and interest the various groups involved, as to the importance of the problem, in an effort to further the program.

In "The City Health Officer Looks at Diphtheria Prevention" (page 425) see description of a movie talkie trailer, and other paragraphs.

In "Occupational Hazards in the Agricultural Industries" (page 462):

Every state board of health, workmen's compensation commission, state and agricultural college, farm advisory board, etc., should

use its offices and bulletins to spread information concerning the methods by which the occupational hazards of the agriculturist may be decreased.

In "Generalized Public Health Nursing Service in Cities" (page 478):

The rôle of the adequately prepared and supervised public health nurse as the interpreter of scientific knowledge in performing family health service under the direction of a generalized public health nursing agency should be of great assistance toward attaining the goals of preventive medicine and public health.

"A Selected Public Health Bibliography With Annotations" (page 515) is the concealing title of material in every issue to be read carefully for source material, leads for timely topics, for titles. Note "While Colds Go Merrily On," title of comment on a medical journal article on "The Common Cold."

"Too Much Pathology?"—A committee of Social Work Publicity Council, looking over some health education material, asked one of its number to comment on a series of weekly releases from a state health department. Here is the result:

This is a worthy effort at health education that should be emulated by state and local health departments throughout the country. As a weekly newspaper release it is a great advance over the limited distribution of weekly or monthly health department bulletins. And emanating, as it does, from an official health source, it has considerably more value, it seems to me, than the average syndicated health column conducted by the individual physician. Better still would be a column, signed or unsigned, to which various health authorities in the state might contribute, under the aegis of the state health department. My point is that such a column representing group thinking and sanctioned by the state health authority would carry more weight and be apt to be sounder, on the whole, than the usual syndicated article which represents only the knowledge, opinion and point of view of the individual writing the column.

The only question as to the series of

articles under consideration is their merit from a journalistic standpoint. They are instructive, clear and even interesting—a good, honest, and solid piece of health education work, but could be more vigorous, stimulating and colorful. They lack a certain “punch” and need more emotional appeal. They sound a bit text-bookish, go too much into the pathology of the diseases they discuss, and are too detailed in their exposition of immunity tests and immunizing procedures. The vocabulary is heavy in spots.—Paul Komora.

Does this comment offer a tentative yard stick for testing our own output?

Health Education in Saskatchewan—A program of education and publicity is outlined in “Activities in a Province-wide Programme for the Control of Tuberculosis,” by R. G. Ferguson, in *Canadian Public Health Journal*, 105 Bond St., Toronto 2, Ont. March, 1935. 35 cents. Says Dr. Ferguson:

However fundamental the facilities for treatment, diagnosis, and follow-up care, of equal importance and much more difficult of attainment is the education of the mass of the people. To the extent that the public are convinced that tuberculosis is curable and preventable, just so far will they avail themselves of facilities for its early diagnosis and care, and will they be willing to pay for the cost of maintaining the programme for its control and eradication.

Dramatization by Girls—In the April, 1935, *Guardian*, Camp Fire Girls, 41 Union Square, New York, N. Y., “Promoting Interest in Health” suggests use of their “Health Chart.”

They will enjoy working out their own dramatization of the points of the chart, presenting brief plays and skits with the health idea for the theme. A few suggestions for such skits are: History of Health Through the Ages, Making Our Own Health Insurance, and How the Doctor Gives a Health Exam.

Care should be exercised in the choice of material for these skits. Be sure the facts are true, worthwhile, up-to-date, and sufficiently interesting to hold the attention of the girls. Such statements as “If you drink coffee you

will not grow up to be a strong healthy woman” should be avoided. Someone will immediately say “Mrs. Smith drank coffee all her life and she is as strong and healthy as anyone in this town.” Make it clear that Mrs. Smith is strong and healthy in spite of having drunk coffee because of her fine healthful heritage and that not all of us are fortunate enough to have had such sturdy, healthy parents and grandparents as Mrs. Smith.

Fads and Superstitions—A fad is said to be “a hobby; freak; whim.” One phase of superstition is “an excessive reverence for, or fear of, the unknown or mysterious.” Both definitions seem to apply to situations met in health education. Attacking those situations expressed in beliefs or emotions may get attention for sound health ideas and information.

“Facts for Food Faddists” in *Consumer's Guide*, Consumer's Council, A.A.A., Washington, D. C. March 25, 1935. Free. Includes paragraphs on acid fruits and milk, roughage, ice cream and sea food, protein and starches, iron in raisins, etc. Food fads

... can be expensive when you are trying to make your food money go far. Getting rid of fads that are false, foolish, or half true may help you plan, buy, and prepare your food more economically.

“Food Fads and Fallacies Relating to Milk.” *Dairy Council Digest*, National Dairy Council, Chicago, Ill. Feb., 1935, gives more detail on some of the points mentioned above.

And Montreal Comes Next—The National Conference of Social Work meets next in Montreal, June 9–16, 1935.

In addition to sessions on social security and other topics, there will be gatherings of health workers, and national health agencies will be represented at Consultation Center, the headquarters grouping of both Canadian and United States national welfare and

health agencies. This will afford opportunities for examining publications and meeting leaders and specialists.

The Social Work Publicity Council will have an extensive display and technical sessions of interest to health workers.

For program information address the National Conference, 82 North High St., Columbus, Ohio.

Milwaukee in October—The Scientific Exhibits should be bigger and better since the idea is getting understood more generally.

The Public Health Education Section will have an interesting and profitable program.

Public Health Education Headquarters will offer a wealth of materials on a wide range of methods and problems.

It is hoped that there will be a modest projection hall for motion pictures and other presentations.

And we will have a chance to meet those in the Health Department and the Wisconsin Anti-Tuberculosis Association who have such a long and interesting record of work in health education.

Regional Round Tables—Staff members of the National Organization for Public Health Nursing are offered for regional groups for the study of administrative and technical problems. Says *Listening In*:

The regional round tables will be tried out in a few selected localities this spring, and in the fall we will be ready to arrange, as far as staff personnel will stretch, to conduct regional round tables at the request of local groups on questions especially related to organization and administration aspects of your jobs in contradistinction to institutes on any one subject. This does not mean that we would not touch on the content of programs or such practical questions as to how to keep records and statistics, but we would not attempt through such round tables to handle just one subject. The discussion rather than

the lecture method will be used so that the group itself will participate and thereby gain from a pooling of experience.

The round tables may be divided into sessions for executives (including supervisors), field nurses, board members—official, non-official—rural or urban, large or small agencies, as seem to fit your need. They might cover from 1 to 3 days with a special time allotment for each group. The N.O.P.H.N. staff member would be available throughout the time when not in conference, for individual interviews. It is hoped that the area covered by these round tables will be fairly large to insure attendance of 30 or 40 people and a widely representative number of agencies. A small fee, maybe 50 cents per person, for any or all of the sessions will be charged to help meet incidental local expenses.

There are a lot of hopeful possibilities in this method in the public health field. Of course we are particularly interested in its application to adult health education.

There might be great gain in getting together representatives from public and private agencies, including the non-health groups doing something in health education in their own constituencies. The editor of this department would like to learn of any who are interested in this idea.

Milwaukee's Report to the Public—"Milwaukee's Health" and "1934" near the top of the cover page of greenish gray, heavy paper; text on fairly heavy rough finished paper; a center spread of 4 pages of full-page photographs that "bleed" on all four sides and the following text made up the Milwaukee, Wis., Health Dept. report:

Health Conservation Contest certificate; Executive Staff; Favorable Health Criteria (2 of them); Some Reasons for the Above Results (one of the 6 is "Accumulative effect of educational measures"); Unfavorable Results (2 of these), with 3 Explanations; Miscellaneous Achievements; General Information; Immediate Needs; Costs (6 items); Comparative Health Statistics (cities over 500,000); a page of Vital Statistics; a page on

Health Department Service to the Community, 1934 (recorded statistically); a page of Expenditures; a page organization diagram.

The Public Seeks the Easy Way—The public always wants to believe in an easy way—a direct method—a *sure* cure. Referring to a recent announcement of some experimental work *The Chaser*, State Tuberculosis Sanatorium, Sanatorium, Texas, says:

It would be a Godsend should the experiment prove satisfactory, but let us not lose sight of the fact that we already know how to prevent and cure tuberculosis. To accomplish this end requires a little more effort than the average person cares to put forth. We, the public, would like to have a vaccine or "shot in the arm" that would immunize us against tuberculosis. Then our troubles and worries would be over. But this so-called vaccine is not available and until it is, let us not drop our hands in our laps in disgust. Let us acquire the knowledge that science has to offer to prevent the spread of this insidious disease and use it in a continuous program for the eradication of tuberculosis. Should such a program be carefully carried out in each community we should soon forget the vaccine idea, for it really would be unnecessary to our health and to the future health of our children.

Copies of what any one has said or has printed to meet such situations would be welcomed by the editor.

Dr. Kleinschmidt Is Abroad—Through the courtesy of the Oberlaender Trust of Philadelphia, which is financing the trip, Dr. H. E. Kleinschmidt sailed on the S.S. New York, March 28 to study exhibit building in Germany, the Netherlands, and Austria. He will also visit Czechoslovakia, Switzerland, France, and England before returning about the end of May.

Hygeia, April, 1935—"Health Pursuits in Pictures," one or more pages in the monthly issues of *Hygeia*, offer possibilities of use in state and local health material. And those in *Hygeia*

may suggest other usable pictures. Any health worker will receive a free copy by writing to *Hygeia*, 535 N. Dearborn St., Chicago, Ill.

Plans for economic security. Guaranteed—but how (cure frauds)? The more common skin infections. Heart diseases of middle life. The childhood type of tuberculosis. Antony Van Leeuwenhoek: first of the microbe hunters (1162-1723). Harvest-mites and ticks (11th parasite). Tooth decay. Shadows (a play). Reëducation of the blind. William Henry Welch. Medicine in ancient America. Eye diseases in adults. Facts and fallacies about milk. The housewife looks at coffee and cerebral beverages. New books on health. Healthgrams. Questions and answers.

"School and Health" this month includes:

The schoolhouse and grounds suggest health teaching. Health teaching in April. Solving health educational problems. How I use *Hygeia* in my health teachings. Adventures in charm: a health program for adolescent girls. A health peep-show. New books for teachers and pupils.

What Is Needed—"What this country needs" more than a good 5-cent cigar, is more talking back by those doing health education.

This department of the *Journal* would mean vastly more to public health education if readers would say more—for or against something or other.

Why don't we hear from those who have held offices in the Section? Those who have been on Section programs? And those who are doing the job but who seldom or never get to the annual meetings?

Speak up, ladies and gentlemen!

As Done by Others—The first value in learning about what others have done is the spur to our own thinking. What some one else has done may do more than to shake one loose from a method or an idea—a no mean help to the health educator. Here is an assortment of what they have done.

"Dialogue-of-the-Day," a series in *Public Health Nursing*, a form of presentation usable in several ways. In the March, 1935, issue "Trichinosis" and "Public Health Nurse" conduct the dialogue. Both characters have one or two needlessly long parts. Broken up more fully by questions and answers the dialogue would gain liveliness. Address 50 West 50th St., New York, N. Y. 35 cents.

"Have You Read?" is a mimeographed page-a-week of reading references issued by Public Health Division of Municipal Reference Library, 139 Centre St., New York, N. Y.

"Health in a Milk Bottle" by Mamie E. Rice of Prince Edward Co. Health Dept., Farmville, Va., describes a county fair exhibit, and illustrates a use of the widely available emergency labor. Illustrated. *Public Health Nursing*, 50 West 50th St., New York, N. Y. Jan., 1935. 35 cents.

The whole exhibit included a fly trap; a manure bin with a fly trap window; a miniature bath room equipped with porcelain built-in tub, stool, and basin all connected up with a septic tank and drainage field; a mosquito exhibit; dental posters and the equipment for a dental clinic in school. In preparing the exhibit of the work of the Nursing Service, I called the VERA to my rescue and was offered the service of an expert workman to build the milk bottle that had been planned, and a local manufacturing company offered the use of their equipment in building the bottle—8 feet tall and 3 feet in diameter. The workman was allowed 3 days in which to do the job. He became so interested that time meant nothing to him and when the bottle was completed it not only was a work of art, but it was generally known that the Health Department was going to have an exhibit at the Fair and Mr. Haga was building a milk bottle at Taylor's to be used in the health exhibit!

With the assistance of the VERA workers, we finally developed what many said was the "most attractive exhibit at the Fair." Food for the family was emphasized. The bottle was divided into four sections—daily food supply for the infant, for the preschool and school child and the family of 5. Dolls were dressed to represent each age group and the

foods suitable and necessary for each group placed on a tray in each section—milk and green vegetables always in evidence. . . .

Posters on a black wall and the white milk bottle towering 8 feet high were in striking contrast to the rest of the colored booths and formed, therefore, an outstanding exhibit.

"A Health Week in Far-off Bengal," by Sister M. Frances. *Public Health Nursing*, 50 West 50th St., New York, N. Y. Dec., 1934. Health local color.

In "I'm Safe from Smallpox: Are You?" Marguerite Breen makes good use of vaccination of Shirley Temple. *Everybody's Health*, 11 W. Summit Ave., St. Paul, Minn. March, 1935. 10 cents.

"Sanatorium Patients Write Newspaper Letters on Tuberculosis" is a page of reproductions of newspaper titles, clippings received in the 1934 newspaper sanatorium letter contest conducted by the Minnesota Public Health Assn. Many patients wrote letters to their home town papers which gave them prominent positions. *Everybody's Health*, 11 W. Summit Ave., St. Paul, Minn. March, 1935. 10 cents.

"The Seven Wonders of the World," health wonders, of course, have been listed in the weekly bulletin of Santa Barbara Co. Health Dept., Santa Barbara, Calif. Dec. 24, 1934. Here is an idea to play with for emphasizing achievements and resources. Health Officer Main credits the idea to a forgotten periodical not devoted to health.

Seven editions of *Health News* are issued, one for each of 7 health districts in New York City. Edited by Savel Zimand (formerly with Bellevue-Yorkville Demonstration), Dept. of Health, 139 Centre St. Mimeographed; 8 pages; one page, outline map of the city; 3 pages of local items; 4 pages common to the whole group.

All ye who edit the table of contents of a popular or professional journal on health are hereby requested to note the new arrangement of the table of con-

tents in *Hygeia*. Each article gets more space in the contents. And with the article title is given bits of information about the author or about the article itself, without digging through an additional page for such supplementary information.

Non-Technic Reading for Technicians—What are the books that will stimulate and enrich our thinking, our writing or speaking, or our planning?

Recently readers of *Printers Ink* voted on a two-foot shelf, not about advertising, which all advertising men should read. Would this list of 16 titles help our readers?

The Bible . . . Middletown, by Lynd
 . . . Shakespeare's Works . . . The Golden
 Bough, by Frazer . . . American Com-
 monwealth, by Bryce . . . The Art of
 Writing, by Quiller-Couch . . . Emerson's
 Essays . . . Fifty Great Selections by
 Ingersoll . . . Our Times, by Sullivan
 . . . Outline of History, by Wells . . .
 Microbe Hunters, by de Kruif . . . Ring
 Lardner's Works . . . Huckleberry Finn,
 by Mark Twain . . . O. Henry's Works
 . . . Jurgen, by Cabell . . . Anthony
 Adverse by Allen.

Contest Craze—A flood of contests via newspapers and radio is discussed in *Business Week*, 330 W. 42d St., New York, N. Y., March 9, 1935. 20 cents.

There isn't any rational explanation for the present rush of contests which got well under way last summer and which has been mounting in intensity all fall and winter. Advertising men, who act first and analyze afterward, point to the rising interest in foreign lotteries as a symptom of the public's craving for contests. Maybe it's all part of the post-depression psychology; maybe the new leisure has something to do with it. Analyses aren't important. To advertisers all that matters is that the public is contest-conscious. Which means that a contest has more than a fair chance of clicking, and when a contest clicks it is one of the best and cheapest forms of advertising.

Public health could not possibly compete with business and industry in

offering prizes. But, as *Business Week* suggests, interest in contests may not be based wholly on prizes. An abiding interest in crossword puzzles with no prizes for their solutions is evidenced by newspaper space given to them.

Many an advertiser still clings to the belief that a successful competition has to have elements of a game in it. Hence the continued popularity of such old favorites as the figure-path, crossword, and identification puzzles, limericks, photograph, word-building, and "what's wrong with this picture?" competitions.

Is not the puzzle idea worth consideration by clever health workers? The "true and false" test, and other newer knowledge test forms seem to offer possibilities, as well as some forms used by advertisers. Is it not possible that some newspapers and a goodly proportion of their readers would welcome non-commercial material?

Please send the editor samples of any contest or puzzle material you have used in times past.

FOR EDUCATION AND REFERENCE

"Comparability of Maternal Mortality Rates in the United States and Certain Foreign Countries," by E. C. Tandy. Children's Bureau. Supt. of Documents, Washington, D. C. 5 cents. Technical, but "Summary and Conclusions" make clear that

This official figure of the United States, which in the last few years has exceeded that of every country except Scotland, remains high no matter what method of assignment is used.

"Dietary Cults, Past and Present," Harriet Morgan. *Trained Nurse*, 468 4th Ave., New York, N. Y. Feb., 1935. 20 cents.

"Food as a Far-Reaching Factor in Health," by H. C. Sherman. *Child Health Bulletin*, American Child Health Assn., 50 West 50th St., New York, N. Y. Jan., 1935. Reprint, 3 cents.

A series of quotations and evidence to

the value and need of public health nursing service. For local publicity. *Free* of National Organization for Public Health Nursing, 50 West 50th St., New York, N. Y.

"Volunteers—An Asset or a Liability." Reprint from *Public Health Nursing*, 50 West 50th St., New York, N. Y. 10 cents.

"Experimentation and Medicine," by A. J. Carlson. *Hygeia* reprint. Am. Medical Assn., 535 N. Dearborn St., Chicago, Ill. 5 cents. Copy free to health worker writing on organization letterhead. If you send copies to your "chief editorial writers" we suggest that you mark the reference to the hunter, fisherman and trapper.

"Obesity" is made up of 4 articles from *Hygeia*. Covers diet, "cures," "treatments," etc. American Medical Assn., 535 N. Dearborn St., Chicago, Ill. 15 cents.

"What You Have Helped Us Do This Year" occupies the inside title page of the miniature annual report of Illinois Society for Prevention of Blindness, 203 N. Wabash Ave., Chicago, Ill. Two pages each of narrative reporting appear under "What you have helped us do on trachoma" and "What you have helped us do for babies."

NEW

Clearance, a tabloid "news digest of western public health and social welfare." "The news of 11 western states—national and foreign news." \$1.00 a year. Preliminary issues underwritten by California Tuberculosis Assn., 582 Market St., San Francisco.

Health succeeds *Michigan Out-Of-Doors*, Michigan Tuberculosis Assn., Lansing. In size 6¾ by 9¾; light weight, dull finished paper keeps down cost but makes possible the good use of half-tones. The cover, on heavier stock, illustrates a new use of photographs—from top to bottom: a ½ inch tint band across the page; a 2 inch

band of white for the title, volume and number; 6½ deep photograph bleeding at both sides; 1¼ inch band of white on which appears the date and "In This Issue" references; with another ½ inch tint block across the bottom.

Health Digest, American Health Publishers, 139 E. 36th St., New York, N. Y. 25 cents an issue. Similar to other "digest" periodicals. Material largely from known acceptable sources.

Although it has started its second volume it is new to us—*Health Progress*, New Jersey Health and Sanitary Assn., Freehold, N. J. Edited by John Hall who cannot avoid an editing job.

News Letter, California Tuberculosis Assn., 45 2d St., San Francisco. Mimeographed cover sheet of colored paper, with printed stock heading, balance of sheet mimeographed.

IN BULLETINS AND JOURNALS

"Ancient and Honorable Hospitals" is a group of old and new pictures—the oldest and some nearly as old. *Bulletin*, American Hospital Assn., 18 E. Division St., Chicago, Ill. April, 1935.

Another example of conversation to present a situation is on the public health nurse page of *New Mexico Health Officer*, Santa Fe. March, 1935.

"The Burden of Mental Disease" is treated in Feb., 1935, issue of *Statistical Bulletin*, Metropolitan Life Insurance Co., New York, N. Y. *Free*.

"Cancer" is the subject of the Nov.-Dec., 1934, issue of *Commonwealth*, Massachusetts Dept. of Public Health, Boston. "Prepared for physicians in the state to enable them to find easily accessible material on cancer, both for use in their general practice and for the preparation of short talks to the public"; 98 pages; also *table of contents*, plus 4-page *index* to the four issues of 1934.

"Insects in Relation to Human

Health" is the theme for the Jan.-March, 1935, issue of *Iowa Public Health Bulletin*, Des Moines, Iowa.

A group of newspaper headlines is reproduced to emphasize an article on heart disease in *The Crusader*, Wis. Anti-Tuberculosis Assn., 1018 N. Jefferson St., Milwaukee, Wis. Feb., 1935. "Wisconsin Becomes Wise about Tuberculosis," in the same issue, is an encouraging report on follow-up visits to 37 back-country people who had been to a chest clinic. There are 4 oblong silhouettes, a brief history of the development of medicine, prepared for Milwaukee Country Day School. Others may wish to use them—various possible uses.

"Learning about Tubercle Bacilli" reproduces compositions from grade school pupils in 1910 after they had heard a lecture by Dr. E. R. Baldwin. *Journal of the Outdoor Life*, 50 W. 50th St., New York, N. Y. April, 1935. 15 cents. Evaluation of such material needs to reckon with the nature of the presentation by the speaker.

"Pioneering in Health Education," by Elizabeth Ulmer. *Public Health Nursing*, 50 W. 50th St., New York, N. Y. April, 1935. 35 cents. A nurse in a state teachers college where students come from a section in which many of the people have never seen a train or read a newspaper."

"A Project in Rural School Health Education," by R. E. Grout. Reprint from Milbank Memorial Fund (40 Wall St., New York, N. Y.) *Quarterly*. Jan., 1935. Free.

"Public Enemy No. 1—The Rat," in *Everybody's Health*, 11 S. Summit Ave., St. Paul, Minn. April, 1935. 10 cents.

"School Health" is one of a "Modern Elsie Series" in which the school nurse does just the right thing, or discovers her errors and promptly rights them. In *Public Health Nursing*, 50 W. 50th St., New York, N. Y. Con-

versation in print is one of the hopeful teaching devices.

REPORTING

Colorado Springs, Colo., in the report of Dept. of Public Health and Sanitation has avoided that typical official printer atmosphere on the cover page, also by the use of dull finished paper for the text. We find no mention of public health education.

"Children's Dentistry in Honolulu" is a report of Palama Settlement Dental Clinic, *Honolulu*, Hawaii, and includes a report of the Division of Dental Hygiene, Dept. of Public Instruction. Effective is this line on the envelope: "How 8 Dentists Cared for 8,445 Children."

The mimeographed report of the *Lake County Health Commissioner* is as simple and inexpensive as possible. It is addressed to the Lake County Board of Commissioners, Crown Point, Ind. A page of narrative is followed by a page with 53 numbered items covering services and other activities, and a page on the work of the sanitary inspector. One improvement at slight additional expense would be to use 4 letter size sheets rather than the 3 legal size sheets.

A biennial report of *Iowa State Dept. of Health*, Des Moines, includes a condensed *table of contents*, a 6 page *index*, and a 25 page section on child health and health education.

Maplewood, N. J., Board of Health, used the mimeograph to advantage in producing its annual report. Printed cover on stiff paper; 5½ by 8½ in size; mimeographed on right pages only; a heading at top of each page.

The report of *New Brunswick Dept. of Health*, Fredericton, carries a "contents" somewhat more detailed than is sometimes the case. There is no direct mention of health education, but a paragraph tells of a dental health campaign conducted in coöperation with

other agencies. Adults as well as school children and teachers were reached.

"*Pasadena Health Activities—1934*" is a 115 page mimeographed report; letter size pages; effective printed stiff cover; *with a 4 page index*; several references to health education, most significant of which is the following:

Members in every division of the Health Department should be capable of giving interesting as well as instructive health lectures and to this end special training is being carried on.

"Days and Deeds of Christmas Seal Dollars," annual report of *Philadelphia* Health Council and Tuberculosis Committee, 311 S. Juniper St. 12 pages; 6 by 9; rough finished paper; type and paragraphing give freedom from sense of crowding; one line heads across the two columns on a page; narrative report with one bar diagram. One page, "Three Factors in the Tuberculosis Movement," concisely describes the parts of official agencies, the medical profession, and the voluntary agencies. The financial report includes a description of every item of expenditure such as:

Health Education Service—Lectures, motion pictures, radio talks, window displays, exhibits, pamphlets, publications, newspaper and periodical publicity (\$14,693.33). Special

campaigns of information on early diagnosis and community tuberculosis problems, conferences, etc. (\$8,398.84). Christmas Seal educational work included in preceding items. Information and advisory service to aid the sick in securing examinations, treatment and care (\$797.52) . . . \$23,889.69.

The Biennial report of *Tennessee* Dept. of Public Health, Nashville, includes a *table of contents* and several groups of photographs illustrating conditions and projects.

The People Want to Know—At least in North Carolina they ask questions, according to *Health Bulletin*, State Board of Health, Raleigh, which says:

In this state, of more than three million people, it is natural to suppose that a large and increasing number of people will be constantly writing to the State Board of Health for definite information on a variety of subjects affecting the health of the people. An inconceivable number of questions on every known subject in the field of medicine and public health are received during the course of every year. Naturally a large proportion of these questions cannot be answered, but many of them can be answered with benefit to the inquirer. The keynote to this service in the replies sent out is information on how to protect the individual families from the ravages of preventable diseases. A large amount of personal advice is offered in such matters as nutrition and immunization against communicable diseases.

BOOKS AND REPORTS

Memoirs of a Small-Town Surgeon
—By *John Brooks Wheeler, M.D.*
New York: Stokes, 1935. 336 pp.
Price, \$3.00.

These memoirs, as they are called, really constitute an autobiography. Conscientious and properly written autobiographies are always interesting as well as valuable. Dr. Wheeler graduated from Harvard Medical School and began his internship in the Massachusetts General Hospital in August, 1878, just when Lister's teachings on surgery were beginning to attract notice in this country. He had the great advantage of not only knowing but serving under many of that wonderful group of men who were teaching at Harvard, and in charge of the Boston hospitals, at that time. There is no question that he made good use of his opportunities and his story brings us, as it were, into intimate personal touch with them in a delightful way.

In 1879 he went to Europe and again had the good fortune of coming into contact with many of the great men of Germany, who had gone further than American physicians in the adoption and practice of antiseptic surgery. He gives interesting sketches not only of those engaged in surgery, which was his chief interest, but also the professors of medicine, obstetrics, anatomy and pathology. He finally settled in Burlington, Vt., where he eventually became Professor of Surgery in the Medical School of the State University.

Approximately one-half of the book is devoted to this period of the author's life, and will have for the average reader the greatest interest. The rest of the book is made up of personal

reminiscences, descriptions of interesting operations, and the hardships of a small town doctor, such as driving 25 miles with the thermometer 20 or more degrees below zero in a sleet storm, and doing operations in kitchens, on kitchen tables and with other make-shift paraphernalia.

The book is pleasingly written and shows a keen sense of humor. It is well printed and has only 4 illustrations, one giving a portrait of the author, and the other 3 giving scenes of operations in 1874, 1893, and in 1934, the first being before antiseptic surgery was practised and the last showing a completely modern operation.

MAZÛCK P. RAVENEL

Rats, Lice and History—By *Hans Zinsser. Boston: Little, Brown. For the Atlantic Monthly Press, 1935. 301 pp. Price, \$2.75.*

Dr. Zinsser has written a very entertaining and instructive book. The major theme has to do with epidemics—typhus in particular—and the influence of these epidemics upon the fate of nations and civilization in general.

Disease is often able to accomplish what generals fail to do, and, in an even more relentless fashion than modern warfare. Any story of typhus must be largely one of animal reservoirs of infection and insect vectors—hence the rats and lice!

The first few chapters give Dr. Zinsser a chance to "explain" and defend his enjoyment from writing of medical drama, and to discourse on a wide range of subjects—"popular science"—the neurosis-conscious biographers, Gertrude Stein. One feels sure that he

had a very good time writing these early chapters!

The discussion of parasitism in general—ushered in by philosophical musings on the origin of life and man's attempt to solve the mystery—gives the fascinating story of parasitic adaptation of infectious microorganisms, the hosts' acquired tolerance, and the resultant shift of the disease in epidemiological importance. Syphilis is an admirable example. The change in habits of the animal host (domestication of the rat) may account for the vanishing of plague from Western Europe.

Although early medical records are often obscure it seems fairly certain that most of our present-day diseases are "old" diseases and that epidemics have played their dramatic rôles in history from the beginning. Plague drove the Spartans out of Greece in the time of Pericles; diseases contributed largely to the fall of Rome; typhus probably led to the defeat of the army of Francis I of France in 1528; plague played a most important part in the outcome of the Thirty Years War; Napoleon was helpless against his opponents, typhus and dysentery.

The genealogy of the louse proves an interesting story, as well as the conquest of the world by the brown rat, who shares many of our human characteristics, according to Zinsser.

After eleven preliminary chapters the subject of typhus proceeds in uninterrupted fashion. The symptoms of typhus, the clinical types, and the transmission of *Rickettsia* bodies to man by the variety of complex parasitic cycles are described. The first undoubted description of typhus dates from 1489 and 1490 during the Civil War in Granada, when 3,000 men were killed by the Moors, 17,000 by disease.

On through the years, and in all parts of the world typhus repeated its grim story. During no war were men free of lice—lice usually meant typhus. In the

World War, typhus broke out in the Serbian army, spread along the entire eastern front, and, from 1917 to 1923, caused more than 25,000,000 cases in the territories controlled by the Soviet Republic and over 2,000,000 deaths. Typhus, though restricted, is not dead.

Dr. Zinsser gives due credit to medical historians and is modest about his own part in the study of typhus.

Some readers may regard parts of the book as a trifle facetious, but again these very parts may give the book a piquancy to other readers. Anyway, it is delightful as well as most informative reading. ANNA DEAN DELANEY

Tuberculosis—By *Fred G. Holmes, M.D.* New York: *Appleton-Century*, 1935. 312 pp. Price, \$2.00.

The tuberculous patient who reads this book will acquire a personal friend as well as wise counsel. He will turn to this friend time and again as he needs information and fresh courage. The present reviewer, approaching his task in a critical mood, found a few errors of fact and of concept, literary laxities and typographical slips, but in the end pushed them all aside as of small consequence as compared with the general effect of the whole. It is the spirit that counts in a book like this. In the process of explaining how tuberculosis acts and what to do about it the author has a way also of reassuring his reader and of inspiring him with confidence. This knack springs out of his own experience with the disease.

Chapter XIII is a good sample. It describes the pathology of tuberculosis but not in the usual medical language, which to a non-medical reader would be dull and incomprehensible. Instead we are invited to witness a thrilling contest involving the invasion of the tubercle bacillus and the stout resistance of the bodily forces. The battle ebbs and flows. There is suspense, despair, hope. Unforeseen circumstances that might

decide the issue are suggested. And throughout the fight, the reader beholds how he himself may give aid to his fighting forces, or, through carelessness or lack of fortitude, connive with the enemy.

Part I of the book is complete in itself for the patient who is treated in the usual manner. Part II deals entirely with surgical methods of collapsing the lung and is for those patients who are receiving collapse therapy or who have it under consideration. The difficult subject of the mechanics of respiration and the principles of pulmonary collapse are simplified. The last, perhaps one of the most valuable chapters, is an informal talk between a physician and his patient dealing with the numerous little problems that confront the patient in his relationships with his medical adviser, his finances, and medical ethics.

In no other disease is the coöperation of the patient more imperative than in tuberculosis. Moreover tuberculosis is a long drawn out struggle giving the patient plenty of time to study the subject. That may account for the many books for the tuberculous patient. But there is still room for this one.

H. E. KLEINSCHMIDT

Standard Classified Nomenclature of Disease—Compiled by National Conference of Nomenclature of Disease. Edited by H. B. Logie, M.D. (2d ed.). New York: Commonwealth Fund, 1935, 869 pp. Price, \$3.50.

This is the second edition of this useful publication, the first official edition having been published in January, 1933. In the meantime, the *Nomenclature* has been installed in the record rooms of 120 or more hospitals, and 27 national organizations have officially approved the list. A number of important hospitals, which were among the pioneers in the classification

and use of hospital statistics, were apparently represented on the Conference Committee only indirectly, and are not as yet listed as users of the *Nomenclature*, possibly preferring to use systems already installed.

As a result of the suggestions from users during the past 2 years, some sections of the *Nomenclature* have been revised or rewritten by the committee in charge, the more important changes occurring in the sections on endocrinology, neurology, and diseases of the cardiovascular and musculo-skeletal systems. The index has been enlarged by about 2,000 items; it now contains nearly 15,000. Code numbers have been simplified somewhat for the benefit of punch-card procedure.

The general plan of classification remains the same as before, each title being classed according to anatomical site and etiology. The code numbers reflect in logical and simple fashion the place of any title under these two criteria. Moreover, they allow for future growth without upsetting the existing system. The *Nomenclature* can truly be said to represent an achievement in scientific classification.

The typography is excellent, except that the highly important introduction is printed in a rather small font. The paper of the pocket edition reviewed may be found to lack the toughness desirable in a book of reference; possibly a more substantial paper back may be available in a desk edition. Otherwise, the physical characteristics of the book are on a par with its well organized content.

A. W. HEDRICH

Community Hygiene — By Dean Franklin Smiley, A.B., M.D., and Adrian Gordon Gould, Ph.B., M.D. (rev. ed.). New York: Macmillan, 1935. 369 pp. Price, \$2.00.

The second edition of this college textbook on public health follows the scheme of the earlier edition, issued in

1929, with the addition of various new facts and a chapter on the cost of medical care. As was stated in the review of the first edition, this material, covering the whole field of community health and sanitation, is sound, well stated, and sufficiently inclusive. There are numerous illustrations, some good, many poor, and some rather antique. The references appended to each chapter are, on the whole, rather elderly and far from adequate. The book has a fairly good index, and its make-up and printing are good. JAMES A. TOBEY

Nutrition and Physical Fitness—By *L. Jean Bogert, Ph.D. (2nd ed.)*. Philadelphia: Saunders, 1935. 566 pp., 65 ill. Price, \$3.00.

Another edition of Dr. Bogert's book a few years after the first publication, attests to its popularity. In its revision, the chapter on the vitamins is expanded and corrected in accordance with recently established facts; the part on atonic and spastic constipation is more fully discussed and special diets recommended; and in accordance with the times, the section on food consumption and costs is explicitly expressed. In its substance, Foods, Body Requirements, Body Processes, Meal Planning, and Diets for Special Conditions, are some of the titles used to describe the parts of the book. And Protein Rich Foods, Fruits and Vegetables, Conditions Which Determine the Energy Requirements, Vitamins—and Where They Are Found, Digestion, Excretion and Factors Affecting It, How to Build Menus, Food Fads and Fancies, Diet after Forty, Malnutrition—How to Detect and Overcome It, and Diseases in Which Diet Is of Major Importance, are the sub-titles used to describe some of the chapters. In general, the book contains a great deal of useful and reliable information on nutrition; but little is written about physical fitness. It is written in an easy style

using simple terms; and thus is a book that should be found very useful to the laity, nurses, and student dietitians.

FRANCIS L. BURNETT

Personal Hygiene Applied—By *Jesse Feiring Williams, M.D. (5th ed.)*. Philadelphia: Saunders, 1934. 529 pp. Price, \$2.25.

A book which has been before the public since 1922, and has run the gauntlet of criticism from which it has come out unscathed so that it has reached its fifth edition, needs little comment. It has proved that it has won a place in public esteem. The present edition has been brought up to date and deserves the commendation which has been given to those which preceded it. MAZÏCK P. RAVENEL

Occupation and Health—*An Encyclopaedia of Hygiene, Pathology, and Social Welfare. Published by the International Labour Office, Geneva, 1934. Distributed in the United States by the World Peace Foundation, 40 Mt. Vernon St., Boston, 1935. (2 vols.) Vol. II, 1294 pp., 207 ill. I-Z. Price (paper), \$11 per vol.; (cloth) \$12 per vol.*

The long awaited second volume of this important work has now appeared. Volume I was reviewed in this *Journal* (Vol. XXI, p. 1288) in November, 1931. As was the case in the first volume, nearly one hundred experts in the field of industrial health have contributed to this work. It is concise and expressed in as simple a form as is consistent with scientific accuracy. It deals with 5 general types of subject matter: industries, harmful substances, diseases, the workers themselves, and specific problems of industrial health.

Each cause of disease is discussed according to a uniform plan under the following headings: Chemistry or Biology, Sources of Intoxication, Toxicity,

Statistics, Pathology, Demonstration in the Environment, Hygiene, Legislation, and Bibliography. The occupational hazards and the various environmental conditions of workers are treated in a similar logical manner.

This volume contains a general discussion of 140 pages entitled *Occupational Diseases*, which includes sections on: Historical Review, Definition and Compensation, Statistics, Clinical Examination, and a discussion of specific diseases classified according to the location of the lesions in the body. This division of the book also contains a résumé of the most important facts about the industrial diseases, arranged in convenient tabular form.

These two volumes form a complete, reliable, and very usable reference work in the field of occupational hygiene. The libraries of universities and health departments in industry will find it invaluable.

C. E. TURNER

Health Stories—Book Two—Curriculum Foundation Series—By Anna B. Towse, Florence E. Matthews, and William S. Gray. Chicago: Scott, Foresman & Co., 1934. 176 pp. Price, \$.68.

A most interesting and useful little book, the average grown-up would call this. It would have to be a disagreeably sophisticated second grade pupil who could not enjoyably imbibe the practice of health habits from this beautifully printed and illustrated series of health stories. And there are notes for the teacher, too, at the end of the book and a vocabulary. Keeping clean and neat; taking care of the body; eating the right foods; keeping well; safety; and keeping happy are the headings of the 6 parts into which the book is divided.

Public health workers with 7 year olds could with profit try out these stories at home.

MERRILL E. CHAMPION

Hygiene and Sanitation—By Jesse Feiring Williams, M.D. (3d ed.) Philadelphia: Saunders, 1935. 372 pp. Price, \$2.00.

This book is well known and needs no criticism. This edition has been revised and brought up to date, giving the latest statistics on mortality and morbidity and much new material on the vitamins. A new section on social hygiene has been introduced. Dr. Williams's books are well known and always worth study. They are a valuable addition to any library. The printing and binding are excellent.

MAZÛCK P. RAVENEL

The Spastic Child—By Marguerite K. Fischel. St. Louis: Mosby, 1934. 97 pp. Price, \$1.50.

The Spastic Child is a story written by a mother telling of the rehabilitation of her son physically, mentally, and socially.

It is interesting reading and should be helpful in bringing a ray of hope to other parents or persons caring for children suffering from Little's disease.

Two points are strongly emphasized throughout the book: first that the care of the spastic child is the parents' responsibility, and second that regular treatment is essential to improvement.

The most valuable suggestion given is that one must teach the child normal habits of motor control before irregular ones are formed.

Self-discipline, the author states, is as necessary for parents of the afflicted child as for the child himself.

This mother makes you feel that to help a spastic child to enjoy as nearly a normal life as possible is a privilege rather than a hardship.

ALLENE SHERRILL

Food Products—By Henry C. Sherman. New York: Macmillan, 1933. Price, \$3.00.

This well known book which has been

standard since 1914, when the first edition was issued, has been completely rewritten. The name of the writer guarantees the authenticity of the material. There are four appendices:

A. The Food and Drugs Act ("Pure Food Law") and Related Regulations and Decisions

B. The Meat Inspection Law and Regulations

C. Calcium, Phosphorus, Iron, Copper, and Manganese Contents of Foods

D. Food Products as Sources of Vitamins

These add greatly to the working value of the book. The printing and binding are excellent.

MAZÏCK P. RAVENEL

Medical Tactics—By Colonels Gustavos M. Blech and Charles Lynch. Baltimore: Thomas, 1934. 205 pp. Price, \$4.00.

The people of this nation are, on the whole, peaceful, but not pacifistic. Every rational citizen has the commendable desire to keep out of another war, but all sensible persons also realize that one of the best guarantees of peace is a reasonable state of preparedness.

Reserve officers of the Medical Department of the United States Army will find this text, written by one of their own colleagues in collaboration with a retired officer of the Medical Corps, a most valuable training manual. Unlike many books on such abstruse subjects as tactics and logistics, it is as interesting as it is instructive, for it is presented in a narrative style, more like a series of stories than a mere pedagogical outline of dull facts.

Since medical officers need more than professional skill in order to achieve military success, they can derive from this book much worthwhile information on the principles of war, the functions of the medical service at the front, and the technic used by this important branch of the army during all types of

armed conflict. Unfortunately, not much attention is given to the Sanitary Corps.

The book is well printed, has a good index, a glossary, a bibliography, and is supplied with several supplementary maps for the working of tactical problems. It is highly commended for its purpose.

JAMES A. TOBEY

Big Problems on Little Shoulders—By Carl Renz, M.D., and Mildred Paul Renz. New York: Macmillan, 1934. 129 pp. Price, \$1.50.

"A grown-up's guide to a child's mind" is the way this book's jacket characterizes the contents and the description is a reasonably apt one. In twelve chapters, various factors which may affect the child's attitude toward life are discussed in simple language. Stress is placed largely on aspects of the feeling of inferiority and on problems of sex. Some of the things that are usually touched on in a manual of this sort are omitted. On the other hand the style is unhackneyed and very readable; the attitude, most sympathetic. Parents will read this book and get a good deal out of it and may be led thereby to go more deeply into the subject of child training.

MERRILL E. CHAMPION

Fundamentals of Dairy Science—By Associates of Lore A. Rogers. New York: Reinhold Publishing Corporation, 1935. 602 pp. Price, \$6.00.

The first edition of this book was greeted with acclaim. It has served a useful purpose and has been widely quoted. It consequently needs no introduction. For this edition the contributions have been revised and brought up to date as far as possible by the original authors, and where this could not be done, by competent men whose names are given under such articles. As

stated in the preface, "This book has been written to fill a need experienced by advanced students and research workers in the field of dairy science." There can be no question that the second edition will receive a welcome equal to that of the first.

The book is well printed and bound, and each chapter has a well selected and extensive bibliography attached. The volume is an American Chemical Society Monograph.

MAZŮCK P. RAVENEL

Practical Everyday Chemistry—By H. Bennett. New York: Chemical Publishing Co., 1934. 305 pp. Price, \$2.00.

This book should prove to be a valuable manual in many laboratories as it gives directions for preparing a variety

of products as well as the composition of many common products. Various chapters give working formulae for adhesives, agricultural products, paints and related products, cosmetics and drugs, food products, beverages, inks and carbon paper, leathers, oils, constructing materials, paper, photography, plating, polishes, rubber and plastics, soaps and cleaners, textiles and many other products in use in daily life. One chapter includes tables, and other useful information regarding sources of information and materials.

Brief introductory paragraphs at the beginning of each chapter are informative. In some cases, these could have been enlarged to advantage. The author has had previous experience as the Editor of the *Chemical Formulary*.

C. S. PEDERSON

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Provincial Health Administration—This history of the Ontario public health administrative development serves as an interesting companion piece to the picture presented in a few of the progressive states south of the border.

ANON. The Development of Public Health In Ontario. *Canad. Pub. Health J.* 26, 3:110 (Mar.), 1935.

School Sanitary Score Card for Nurses—Record form devised by a school superintendent to enable the school nurses to give a more complete picture of the sanitary aspects of the school in their monthly reports.

ANON. The American School Board Journal, 90, 2:30 (Feb.), 1935.

Decline in Births Halted?—In New York City the last 4 months of 1934 showed an increase in births over the corresponding period of the pre-

vious year for the first time in years. The increase was 1,265 births, compared with declines averaging over 2,000 for the period since 1930. The same publication reprints a review of the 1934 mortality by cause, which had been released to the press as of January 1. Quite a performance!

ANON. *Quart. Bull., Department of Health, New York City.* III, 1:5-18, 1935.

Pellagra Declines—The death rate in 12 states has dropped more than half since 1929. This Bulletin also contains a review of 1934 industrial mortality from various causes.

ANON. Pellagra Deathrate Continues to Decline. *Stat. Bull., Met. Life Ins. Co.* 16, 1:5 (Jan.), 1935.

Longevity Increases—The expectation of life at birth among Metropolitan policy holders was 59.1 years in 1933, an increase of 1.8 years since 1930, this

in spite of the depression. The reasons are still cause for speculation. Each age, color, and sex benefitted from the mortality decline.

ANON. Longevity of Industrial Policyholders During the Depression. *Stat. Bull., Met. Life Ins. Co.* 16, 2:1 (Feb.), 1935.

Statistics of Murder—Negroes, foreign born (especially Italians), single males, and married females loom up among the victims of homicide. The conviction rate for murder is highest for Italians; but juries discriminate notoriously against the foreign born.

DEPORTE, J. V., and PARKHURST, E. Homicide in New York State. *Human Biology*, 7, 1:47-73 (Feb.), 1935.

Pro BCG—In the research reported, BCG cultures did not acquire virulence on liquid media containing serum or in depths of nutrient broth or by successive selection of smooth-appearing colonies or by repeated animal passage. This is offered as counter evidence to the claims that BCG may develop virulent variants.

BEHNER, D. M. The Stability of the Colony Morphology and Pathogenicity of BCG. *Am. Rev. Tuberc.* 31, 2:174 (Feb.), 1935.

Infectious Periods of Venereal Disease—Syphilis should be considered infectious until after 6 months of intensive treatment; gonorrhea in men until 6 months after all evidence of the disease, women until after 3 months, and children 1 month.

CASSELMAN, A. J. When Is a Person with a Venereal Disease Dangerous? *Pub. Health Nurs.* 27, 4:186 (Apr.), 1935.

Debunking Vitamin A vs. Resistance to Disease—Though a loss of resistance to infection does occur in adults with outspoken deficiencies of vitamin A and probably vitamin C, the addition of these vitamins to an already normal diet will not increase immunity to infection. However, in infancy a

state of susceptibility does occur, which persists and is preventable by an adequate diet especially rich in vitamin A.

CLAUSEN, S. W. Nutrition and Infection. *J.A.M.A.* 104, 10:793 (Mar. 9), 1935.

The Sick and the Dead—Major causes of death are not the most frequent causes of sickness; the degenerative diseases lead the death causes, whereas the respiratory diseases lead the latter (whether disabling or non-disabling). Illness is most frequent under 5 and least frequent at 15-19. These are but two of many useful findings resulting from an extensive family illness survey.

COLLINS, S. D. A General View of the Causes of Illness and Death at Specific Ages. *Pub. Health Rep.* 50, 8:237 (Feb. 22), 1935.

Pardonable Choler—Medical broadcasts considered alone are good publicity. But they cannot be considered alone. If the problem of rickets prevention is presented, every food in the market appears as its vehicle. When it is suggested that people should avoid colds, we find them gargling a half dozen flavored solutions because they are told through the same publicity media that this is the way to avoid colds. Perhaps the worst hallucination the medical profession ever sanctioned was the idea that bowels should move every day. If the broadcaster cannot be specific, somebody else can, so we bait the hooks and they catch the fish.

COMMITTEE ON PUBLIC HEALTH. The Hazards of Publicity. *New Eng. J. Med.* 212, 12:525 (Mar. 21), 1935.

Irradiated vs. Yeast Milk—Of the milks used in this comparative study, irradiated milk contained per unit of measure more vitamin D than did the yeast milk.

GERSTENBERGER, H. J., *et al.* Antirachitic Cow's Milk. *J.A.M.A.* 104, 10:816 (Mar. 9), 1935.

More Amebic Dysentery—During the Chicago stockyards fire, heavily polluted water was drunk by firemen and spectators. A high percentage of the exposed became infected with *E. histolytica* and some with typhoid bacilli, causing acute diarrhea. The evidence is unmistakable that amebic dysentery is a water-borne disease.

HARDY, A. V., and SPECTOR, B. K. The Occurrence of Infestation with *E. Histolytica* Associated with Water-Borne Epidemic Diseases. Pub. Health Rep. 50, 10:323 (Mar. 8), 1935.

Stream Pollution and Purification—The rate of stream purification depends upon the relation of wetted surface. It is slower in deep sluggish channels and faster in broad shallow riffles. Attached plankton on stream bottoms plays a large part in bacterial destruction.

HOSKINS, J. K. Bacterial Purification Rates in Polluted Water. Pub. Health Rep. 50, 12:385 (Mar. 22), 1935.

About Measles Prophylaxis—Measles infection probably depends upon the degree of exposure (as do other infections). If this is so, there is danger of jumping to erroneous conclusions about the prophylactic value of usual doses of adult blood which protect under hospital conditions.

KARELITZ, S., and SCHICK, B. Epidemiologic Factors in Measles Prophylaxis. J.A.M.A. 104, 12:991 (Mar. 23), 1935.

School Health Administration—Student health records used in the schools of a Michigan City as they are integrated into school health programs are presented in interesting detail to indicate that they are purposive, educational, scientific and practical.

KLEINSCHMIDT, E. E. Purpose and Function of School Health Records. Pub. Health Rep. 50, 9:281 (Mar. 1), 1935.

"Tuberculosis Causes Tuberculosis"—Case finding and case control

in tuberculosis are presented simply and clearly so that every sanitarian may quickly grasp the essentials of the epidemiology of the disease. Thus is left no excuse for half-hearted, lop-sided control programs.

KLEINSCHMIDT, H. E. Controlling Tuberculosis. Pub. Health Nurs. 27, 3:129 (Mar.), 1935.

What Makes a Good Public Health Nurse?—An account of the panel session held at the Pasadena, Calif., A.P.H.A. meeting last September and the conclusions reached on the qualifications for public health nursing.

MACDOUGALL, E. F. What Is the Most Important Quality for Success in a Public Health Nurse? Illinois Health Messenger, 7, 5:45 (Mar. 1), 1935.

A Bird's Eye View of Public Health Nursing in This Country—Pointing out trends in public health nursing at the present time and making recommendation in regard to future developments.

McIVER, P. Public Health Nursing in the United States. Illinois Health Messenger, 7, 5:45 (Mar. 1), 1935.

Protecting against Measles—Measles is most dangerous to children under 2. Every effort should be made to keep them from contact with cases. If they are exposed, they should be given protective doses of convalescent measles serum. Pooled adult serum or whole blood from parents may be substituted when convalescent serum is not available.

MEADER, F. M. Serum Prophylaxis for Measles. Am. J. Nurs. 35, 3:199 (Mar.), 1935.

Why Maternal Deaths Continue—Highlights from a study of a nationwide sampling of maternal deaths reveal that one-fourth of the total followed abortions, that 4 out of 5 had poor or no prenatal care. Though there has been a reduction of about 1

per cent a year in maternal deaths in those states reporting since 1921, much remains to be done.

ROTHERI, F. C. New Light on Maternal Mortality. *Med. Women's J.* 42, 3:59 (Mar.), 1935.

Public Health in Nursing Schools—A good exposition of ways the nursing school can better prepare students for the preventive aspect of nursing care.

STIMSON, M. What the Community Expects of Nurses Doing Public Health Work. *The Bulletin (Massachusetts State Nurses' Assn.)* 4, 1:5 (Mar.), 1935.

Causes of Congenital Deafness—The suggestion is made that the administration of quinine to the mother during the prenatal period may be responsible for deafness in the baby. (The salicylates and alcohol may also be dangerous.) It is proposed to get the history of all mothers of deafened infants.

TAYLOR, H. M. Further Observations on Prenatal Medication as a Possible Etiologic Factor of Deafness in the New-born. *South. M. J.* 28, 2:125 (Feb.), 1935.

Protection against Diphtheria—In Leeds (Eng.) 8 of the 13 serum-treated cases of diphtheria gave a negative Schick reaction at the time of the onset of illness. Blood titration of these cases indicated that 5 of these should have been definitely immune (according to the accepted standard of antitoxin level of immune subjects). Non-immunized children enjoyed a diphtheria rate of 11 per 1,000. Among the immunized the rate was 5.4 per 1,000.

Media Suggested as Substitutes for the Standard Nutrient Agar Used in Routine Milk Control Work

ROBERT S. BREED, PH.D., F.A.P.H.A. (*Life Member*)

New York State Agricultural Experiment Station, Geneva, N.Y.

WHEN the first Standard Methods of Milk Analysis report was drawn up by the American Public Health Association in 1910,¹ the committee in charge of the work made many comparisons between nutrient agars then in use before selecting a beef infusion agar as standard. At the time that this agar was selected, there was much opposition to this choice because it was an inconvenient and expensive agar to prepare and because variations in composition occurred when it was prepared in different laboratories. Beef extracts were also being used extensively at that time. Soon afterward² the Laboratory Section of the American Public Health Association took action replacing the meat infusion agar with a plain peptone-beef extract agar because it was cheaper and more easily prepared. This has since been generally known as standard nutrient agar.

Later,³ the amount of peptone used was reduced from 10 gm. to 5 gm. per liter, and the amount of beef extract from 5 gm. to 3 gm. per liter. At the time that beef extract agar was selected, it was generally thought that this agar would develop a reasonably constant proportion of the total number of bacteria present. Soon after the war period, partially perhaps because of the use of American made peptones, it was found that certain types of bacteria grew so

poorly on so-called standard nutrient agar that the colonies produced were of very small size and difficult to count. The term "pin-point" colonies came to be used in connection with these organisms. The tiniest of these colonies in raw milk have generally been found to belong to the streptococci. Ordinarily they are the streptococci causing bovine mastitis. In pasteurized milk, these bacteria were sometimes streptococci so heat resistant that they were capable of surviving pasteurization temperatures. In other cases, these pin-point colonies were produced by spore-forming types known as facultative and obligate thermophiles. Some of the latter are actually capable of growth in the milk in the holding vats during pasteurization.⁴

As bacteria that do not grow readily on the ordinary standard agar are only occasionally present in milk samples, and as they frequently do not develop visible colonies, this condition of affairs leads to gross errors in the bacteria counts made on standard nutrient agar when these bacteria are present. Recently conveniently available and reasonably cheap materials have been developed which are capable of growing all of these types of bacteria when added to ordinary agar. For this reason it has seemed desirable to attempt to develop a new nutrient agar for use in Standard

Methods of Milk Analysis. Such an agar has been developed by Bowers and Hucker who have reported the results of their studies in a recent publication.⁵ As this new agar is so promising, it is hoped that milk control laboratories will prepare some of it for use in a series of comparisons with ordinary standard agar in order that they may determine for themselves the advantages of the newly proposed medium.

It will be noted that the new medium contains a small amount of glucose. It has been known for many years that the addition of lactose or glucose to standard agar tends to develop larger and more easily counted colonies (Sherman, 1916, and others).⁶ Europeans also have frequently favored the use of a sugar in media of this type.

In recent years there has been in Europe a greatly increased interest in the development of an agar similar to the standard agar used in North America for use in routine milk control work. In England particularly, a committee is engaged at the present time in a study of this problem. One of the suggestions that has been developed in that country is the use of 0.5 per cent to 1.0 per cent skim milk in standard nutrient agar. The skim milk seems to add certain nutrient materials that are very desirable and it is normally easily obtainable.

Some German authorities⁷ are urging an international standardization of laboratory methods for the examination of milk by the International Dairy Congresses sponsored by the International Dairy Federation of Brussels, Belgium. German bacteriologists have tentatively recommended the use of a lactose-peptone-meat extract agar which is to be incubated at 30° C.

As there is an advantage in the use of a common agar for this work throughout the world, an effort is being made at the present time to bring about coöperative international studies that

we hope may result in the adoption of common standard agar.

The formula of two agars that have been suggested as substitutes for the present standard nutrient agar are as follows:

I. *Tryptone Glucose Skim Milk Agar*—Developed by C. S. Bowers, New Britain, Conn., and G. J. Hucker, Geneva, N. Y. The preparation and the composition of the medium* is as follows:

Tryptone (Difco)	5 grams
Glucose	1 gram
Agar	15 grams
Skim milk (fresh)	5 c.c.
Distilled water	1,000 c.c.

The Tryptone (hydrolyzed casein, obtainable from Digestive Ferments Company, Detroit, Mich.) and glucose dissolve immediately in the distilled water without the aid of heat. The agar is then added and melted in an Arnold sterilizer. (An open flame with constant stirring, or other methods, could undoubtedly be used, but the Arnold was utilized in order to dispense with the constant attention necessitated when an open flame is used.) Five c.c. per liter of *good quality* skim milk are then added, and the heating continued for about 5 minutes to insure a thorough distribution of the milk throughout the agar.

Sterilize in autoclave 20 minutes at 15 lb. pressure.

Prolonged heating in the autoclave should be avoided.

The final reaction should be approximately pH 6.6.

As American laboratories may also wish to try the English modification of standard agar, detailed directions are given below as received from England.

II. *English Modification of Standard Agar*—Primarily developed at the Dairy Research Institute, Reading, England, and in the Laboratories of the United Dairies, London England.⁸

(Procedure used in America)

Prepare standard nutrient agar as usual, adding 5 c.c. of *good quality* skim milk per 1,000 of agar just before autoclaving.

* Obtainable in dehydrated form, skim milk and distilled water to be added later. Digestive Ferments Company, Detroit, Mich.

(Procedure used in England as suggested by
L. J. Meanwell, London)

Beef Extract (Lemco).....	3 grams
Peptone (British Drug Houses)*..	5 grams
Shredded agar	15 grams
Raw milk	5 c.c.
Distilled water	1,000 c.c.

1. Weigh out agar and place in muslin bag. Wash in running water until required (15-30 min.).

2. Dissolve beef extract and peptone in distilled water, in the steamer for 3 hours.†

3. Adjust reaction at room temperature to pH 6.8, using brom thymol blue as indicator.

4. Squeeze out excess water from washed

* It has been found B.D.H. Peptone gives a clearer medium than other brands that have been tried.

† Although the Lemco and peptone dissolve very readily, the extra period in the steamer prevents a cloudy mixture.

agar, and add together with 5 c.c. of raw milk to Lemco-peptone broth.

5. Autoclave at 15 lb. for 20 minutes.

6. Filter immediately through paper pulp (Whatman No. 3) in Buchner funnel.

7. Adjust reaction to pH 6.7.

8. Tube into 10 c.c. quantities, autoclave at 15 lb. for 20 minutes.

The final reaction should be pH 6.6.

Our Front Window

CHEMISTS of the nation will do themselves proud this month when they celebrate 300 years of the development of chemical industry in this country. It all harks back to John Winthrop, Jr., first colonial governor of Connecticut, who in 1635 mapped out an ambitious program for production of salt, iron, glass, potash, tar, black lead, saltpeter, medicines, copper, alum, and other chemicals. Winthrop was son of the Pilgrim governor of the Massachusetts colony. He was first to import

chemical apparatus for a laboratory.

And to think that in his day men believed that the way to cure a bayonet wound was to rub the medicine on the bayonet! Three hundred years is not a long time, if you think in terms of geology, or even of man's little day upon this planet. In the past 300 years, pharmacy has come all the way from the alchemist and the magician. We'll bet our descendants 300 years hence will think we were old fogies, too.—*Am. Druggist*, Apr., 1935, p. 10.

ASSOCIATION NEWS

SIXTY-FOURTH ANNUAL MEETING

MILWAUKEE, OCTOBER 7-10, 1935

Headquarters: Hotel Schroeder

SCIENTIFIC EXHIBITS AT MILWAUKEE

MEMBERS of the Association are invited to present new, interesting, or important material for the 3rd Annual Scientific Exhibit to be held in conjunction with the 64th Annual Meeting of the American Public Health Association.

Two special features are offered by the Scientific Exhibits Committee this year. The first, which has been welcomed by section program committees, is the opportunity for authors on the scientific program to illustrate their papers with exhibits in the scientific exhibits. In many instances, interesting charts, graphs, apparatus, or materials relating to a programmed paper cannot be easily displayed at a section meeting. Sometimes the crowded program prevents delegates from examining such illustrative material. The scientific exhibit offers to authors a chance to present such illustrative material—thus making it available to those in attendance during the entire period of the meeting.

The second feature which the committee hopes to offer is an exhibit from Great Britain. The Royal Sanitary Institute, at the invitation of the Scientific Exhibits Committee to sponsor an exhibit from Great Britain, has appointed a committee of its Council to consider the matter with other public health organizations in Great Britain.

Although standard requirements for exhibitors are developing, the com-

mittee has not for this year established any requirement that would exclude any appropriate exhibit in the public health field. It is assumed that most exhibits offered will fall into one of the following classifications:

1. Devices developed by laboratories, health officers, and others for economy or efficiency in their work. Several interesting exhibits of this nature were shown last year under the general heading of "Gadgets."

2. Documents, charts, books, photographs, and other material of a historical nature relating to some phase of pioneer public health work.

3. Statistical or research data or technic, illustrating results or methods of recent study of public health problems.

4. Organization and procedure, particularly in the field of administration and inter-organization relationship dealing either with special programs or campaigns or routine activities of especial interest or merit.

5. General activities, services, and material available for and of interest to public health workers. Exhibits of the national voluntary organizations will be principally included in this group.

This grouping is not set up as an iron-clad classification into which all exhibits must be fitted. It is offered as a suggestion of types of acceptable material.

The Scientific Exhibits Committee reserves the right to accept or decline any exhibit offered to it—if it does not feel that the exhibit meets the requirements of the committee or does not come up to A.P.H.A. standards.

A new feature of the exhibits this year will be the award of honorable

mention to exhibits that show particular merit especially in their presentation. These citations of merit are not limited in number and will be awarded to all exhibits selected for the purpose by the committee. Citations will be reported to the Governing Council of the Association and to the membership through the *Journal*.

LABORATORY SCIENTIFIC EXHIBITS

THE Chairman of the Committee on Scientific Exhibits of the Laboratory Section, requests that members of the section submit material for a laboratory exhibit at the Milwaukee meeting as soon as possible.

It is desired to show the newer technical procedures in so far as they may be practically demonstrable and such other laboratory methods and apparatus as are of current interest.

Communications should be addressed to the *Chairman*, Dr. Fred O. Tonney, Director, Technical Service and Research, Board of Health, Chicago, Ill.

Personnel of Committee

FRED O. TONNEY, *Chairman*
 MAJOR A. PARKER HITCHENS
 M. H. MCCRADY
 RUTH GILBERT

Members of the Association, or their associates who have material of interest for exhibit to the members of the public health profession, may secure application blanks and further information from Homer N. Calver, Chairman, Committee on Scientific Exhibits, American Public Health Association, 50 West 50th Street, New York, N. Y.

ROYAL INSTITUTE OF HYGIENE

DR. ATWATER is pleased to announce the appointment of John L. Rice, M.D., Health Commissioner of New York City, Fellow of the Association, as representative of the A.P.H.A. at the forthcoming Health Congress of the Royal Sanitary Institute, to be held at Bournemouth, England, July 15-20.

Sandor Horwitz, M.D., Health Officer of Peoria, Ill., will also attend the Bournemouth Congress, not only as a Fellow of this Association but also as the representative of the Illinois Department of Public Health.

SOUTHERN BRANCH MEETING

THE Southern Branch of the American Public Health Association will meet in St. Louis, Mo., November 19 and 20, 1935.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Robert M. Bardin, M.D., Box 448, Rutherfordton, N. C., Rutherford County Health Officer
 Osborne E. Carr, M.D., 901-4th Ave. E., Owen Sound, Ont., Canada, Medical Officer, Sydenham Township
 F. R. Nicholas Carter, M.D., Health Department, South Bend, Ind., Health Officer
 Edwin G. Clark, M.D., Criminal Court Bldg., Nashville, Tenn., Assistant Health Officer, Davidson County
 Owen C. Fisk, M.D., Department of Health, Cincinnati, O., Acting Commissioner of Health

Wendell A. Jones, M.D., Court House, Riverside, Calif., City and County Health Officer
 Frederick W. Morse, Health Department, Haverhill, Mass., Agent, Board of Health
 John C. Neale, Jr., M.D., Health Department, Richmond, Va., Henrico County Health Officer
 Thomas F. O'Brien, M.D., 622 Broadview Terrace, Hartford, Conn., Deputy Superintendent of Health

Laboratory Section

Paul J. Beard, Ph.D., Bacteriology Dept., Stanford University, Calif., Assistant Professor of Sanitary Sciences

Elizabeth T. Mathewson, 1208 S. 8th St., Sheboygan, Wis., Supervisor, State Cooperative Laboratory of Hygiene

Stuart Mudd, M.D., University of Pennsylvania Medical School, Philadelphia, Pa., Professor of Bacteriology

Gustave A. Ootmar, M.D., Okanayan Union, B. C., Canada, Medical Health Officer, Kelowna Health Unit; Director, Provincial Board of Health Laboratories

Maurice F. Schlesinger, 47 Third Ave., New York, N. Y., Laboratory, Bendiner & Schlesinger

Clifford N. Stark, Ph.D., Dept. of Dairy Industry, Cornell University, Ithaca, N. Y., Professor of Bacteriology

Vital Statistics Section

Joseph Berkson, M.D., D.Sc., Mayo Clinic, Rochester, Minn., Head of Department of Statistics

John R. Miner, Sc.D., 1901 E. Madison St., Baltimore, Md., Associate Professor of Biology, School of Hygiene & Public Health, Johns Hopkins University

Charles A. Taylor, Life Insurance Company of Virginia, Richmond, Va., Life Insurance Actuary

Public Health Engineering Section

Henry C. Lane, 3154 N. Sawyer Ave., Chicago, Ill., Junior Assistant Sanitary Engineer, Board of Health

William V. Leonard, Dept. of Public Welfare, Boise, Idaho, State Chemist and Sanitary Engineer

Industrial Hygiene Section

Thomas E. Lightfoot, 1022 Koopers Bldg., Pittsburgh, Pa., Engineer in Charge of Accident Prevention and Compensation, Koopers Coal & Transportation Co.

Bernice A. Strange, R.N., American Can Co., Richmond, Va., Industrial Nurse

Food and Nutrition Section

Benjamin R. Allison, M.D., 26 Ives Rd., Hewlett, L. I., N. Y., Practicing Physician

Bess Exton, C.P.H., 1001 Begole St., Flint, Mich., Executive Secretary, Genesee County Tuberculosis Assn.

Richard C. Johnson, City Hall, Albert Lea, Minn., City Health Inspector

William T. Murray, 3 Commercial St., Boston, Mass., Frosted Foods Sales Corp.

Child Hygiene Section

Louis Judelsohn, M.D., 147 Brunswick Blvd., Buffalo, N. Y., Pediatrician

Dr. Abraham B. Schwartz, 2018 E. North Ave., Milwaukee, Wis., Chairman, Child Welfare Committee, Milwaukee County Medical Society

Public Health Education Section

C. W. Kammeier, 610 Flynn Bldg., Des Moines, Ia., Executive Secretary, Iowa Tuberculosis Association

George A. Skinner, M.D., 552 S. 58th St., Omaha, Nebr., Professor of Public Health, University of Nebraska Medical School

Public Health Nursing Section

Anna E. Akerfelt, 2 Philemon St., Bridgeport, Conn., School Nurse

Dorothy M. Concannon, R.N., 2 Elam Ave., Miami, Ariz., Rural Health Nurse

Epidemiology Section

Samuel Frant, M.D., 1605 Nelson Ave., New York, N. Y., Chief, Division of Epidemiology, Bureau of Preventable Diseases, New York City Dept. of Health

Edward M. Holmes, Jr., M.D., State Health Dept., Richmond, Va., Assistant State Epidemiologist

Winston H. Tucker, M.D., Ph.D., 539 S. Grand Ave., W., Springfield, Ill., Assistant Epidemiologist, State Dept. of Public Health

Unaffiliated

Cecil K. Drinker, M.D., S.D., 55 Shattuck St., Boston, Mass., Acting Dean and Professor of Physiology, Harvard School of Public Health

Eleanor E. Kelly, 15 Short St., Brookline, Mass., Supervisor of Social Service, State Dept. of Public Health

DECEASED MEMBERS

George H. Bigelow, M.D., Boston, Mass., Elected Member 1923, Fellow 1929

Kathryn Schulken, R.N., Denver, Colo., Elected Member 1931, Fellow 1934

J. A. Chevigny, M.D., Hammond, Ind., Elected Member 1931

Marguerite J. Clancy, R.N., Asbury Park, N. J., Elected Member 1926

J. H. Kuser, M.D., San Rafael, Calif., Elected Member 1920

G. H. Sherman, M.D., Detroit, Mich., Elected Member 1918

NEWS FROM THE FIELD

SUMMER SCHOOL COURSES IN PUBLIC HEALTH

While the following list does not show all universities and technical schools offering summer courses in public health, it represents those who have replied to a questionnaire sent out by the American Public Health Association.

American National Red Cross

Courses in Teacher Training for Home Hygiene Instructors:

University of California, Los Angeles,
Calif.—June 22–August 2

Colorado State College, Fort Collins,
Colo.—July 13–August 23

Peabody College, Nashville, Tenn.—June
10–July 17

Pennsylvania State College, State College,
Pa.—July 1–August 9

Syracuse University, Syracuse, N. Y.—July
8–August 16

University of California, Berkeley, Calif.

June 24–August 2

General Bacteriology

Child Development and Training

History of Nursing

Principles and Practice of Public Health
Nursing

SIGHT SAVING CLASSES

COURSES for the training of teachers and supervisors of sight-saving classes will be offered as follows:

Western Reserve University, Cleveland, Ohio—June 24 to August 2.

State Teachers College, Buffalo, N. Y.—July 1 to August 9.

Teachers College, Columbia University, New York City—July 8 to August 16.

Details may be obtained from the university or college or from the directors in charge.

Olive S. Peck, Supervisor of Sight-Saving Classes of Northern Ohio, Board of Education, Cleveland, Ohio

Matie M. Carter, Supervisor of Sight-Saving Classes, State Education Department, Albany, N. Y.

Winifred Hathaway, Associate Director, National Society for the Prevention of Blindness, 50 West 50th Street, New York City.

GRANT FOR DENTAL RESEARCH

CONTINUANCE of a dental research project in Yale University School of Medicine has been made possible through a grant of \$17,500 by the Carnegie Corporation of New York. This program, instituted in July, 1929, under a grant of the Rockefeller Foundation, is an intensive study of the teeth in relation to the body in general by physicians, radiologists, bacteriologists, pathologists, and dentists.

Connected with this project is the recent formation of the Dental Clinic Society, which provides more than 500 treatments monthly for indigent patients. The society has its own professional staff but is conducted in close coöperation with the dental study group and community social agencies.

TESTING OF FILTER-TYPE RESPIRATORS

IN view of the increasing importance of the problem of dust control in mining and other industries, and in line with its policy of testing respiratory protective equipment for permissibility for use in mines and in the mineral industry, the U. S. Bureau of Mines, Department of the Interior, has formulated a series of tests for determining the efficacy of filter-type respirators designed for use against mechanically generated dusts, fumes of various metals, and mists. These tests are described in *Schedule 21*, "Procedure for Testing Filter-Type Dust, Fume, and Mist Respirators for Permissibility."

NEW WING TO MARINE HOSPITAL

A NEW five hundred thousand dollar addition to the U. S. Marine Hospital of Chicago was dedicated recently, with Surgeon General Hugh S. Cumming, F.A.P.H.A., of the U. S. Public Health Service, Washington, D. C., presiding at the ceremonies. The hospital was founded in 1873.

CANCER PROGRAM IN ONTARIO

A NEW cancer commission for the province has been named by Dr. James A. Faulkner, newly appointed Minister of Health for Ontario, to continue a cancer program begun several years ago. Three clinics have already been established in Toronto, Kingston, and London, with an expenditure of \$300,000 on radium.

ACCIDENTAL DEATHS IN 1934

ACCIDENTS of all kinds took 99,000 lives in the United States last year, according to preliminary estimates just announced by the National Safety Council. More than a third of the deaths occurred in traffic, another third in homes, and the remainder in occupational and public accidents.

The total death figure for 1934 represents an increase of 8.7 per cent over 91,087 deaths recorded in 1933 and approximates the all-time high of fatal accidents reached in 1930, when there were 99,300 deaths.

Motor vehicle accidents were responsible for the largest proportion of the grand total—35,500 fatalities. This total was 13 per cent above 1933 and well above the previous all-time high of 33,675 in 1931.

Home accident deaths jumped from 30,000 in 1933 to 33,000 last year. Occupational deaths are estimated at 15,500, an increase of 1,000 over 1933.

The new record of traffic deaths, an increase of 4,000 in a single year, is only partially accounted for by increased auto travel. Gasoline consumption, the best index of travel, increased only about 7 per cent.

The increase in fatal accidents was general throughout 1934; every month showed a higher death total than the corresponding month of 1933. The first six months, however, were especially disastrous, showing an increase of 21 per cent.

Increases in motor vehicle deaths were much greater in rural areas than in the city. Pedestrian fatalities increased less in 1934 than other types of traffic accidents, but they still average between 60 and 65 per cent of motor vehicle deaths in cities.

The cities showing decreases in auto deaths were: San Francisco, with a drop of 15 per cent from 1933; Pittsburgh, 13 per cent; Milwaukee, 8 per cent; New York, 1 per cent.

FEDERAL DIVISION OF VITAL STATISTICS

THE third regional conference of the Division of Vital Statistics of the Federal Bureau of the Census with registration officials was held in Albany on March 22. Nine of the 10 northeastern states comprising the conference territory were represented. The previous conferences were held in Montgomery, Ala., and in Des Moines, Ia.

A. W. H.

WHERE TO FIND QUALIFIED PUBLIC HEALTH NURSES?

THE Joint Vocational Service which is the vocational and placement service of the National Organization for Public Health Nursing with headquarters at 130 East 22nd Street, New York, N. Y., on January 1, 1935, had 524 candidates, scattered over the whole country, listed for placement in the public health nursing field. The Service has professional histories and credentials of these nurses on file and can give helpful service to those seeking good public health nurses.

E. F. M.

LIBRARY OF AMERICAN STUDIES IN ITALY

THE Library for American Studies in Italy, through Dr. Giovanni Perilli, Via Cunfida 35, Roma (48), announces its intentions of extending, for the benefit of American and Italian readers, its section of medical books and periodicals. It requests contributions of publications from the members of the A.P.H.A.

MILBANK FUND HEALTH CONFERENCE

THE Milbank Memorial Fund held its annual two-day conference in the New York Academy of Medicine, March 27 and 28. Dr. Livingston Farrand, F.A.P.H.A., President of Cornell University, opened the Conference. There were five simultaneous round-table discussions.

Dr. Thomas Parran, Jr., F.A.P.H.A., New York State Commissioner of Health, presided at the session on Venereal Diseases. Dr. Joseph Earle Moore, of the Syphilis Division of the Medical Clinic at Johns Hopkins University, was one of the discussants.

Those presiding at other sessions were: Dr. Kendall Emerson, F.A.P.H.A., Managing Director of the National Tuberculosis Association, on Health Education; Dr. C.-E. A. Winslow, F.A.P.H.A., Professor of Public Health at the Yale School of Medicine, on Public Health Problems; Professor Robert E. Chaddock, of the faculty of political science at Columbia University, on Population Studies; and Dr. Charles J. Hatfield, Executive Director of the Henry Phipps Institute, Philadelphia, on Tuberculosis Studies.

Dr. Raymond Pearl, F.A.P.H.A., Professor of Biology, School of Hygiene and Public Health at Johns Hopkins, was one of the speakers at the session on Population Studies.

Speakers at the annual dinner, which closed the meeting March 28, were Surgeon General Hugh S. Cumming, F.A.P.H.A., Dr. Simon Flexner, and Josephine Roche.

JOINT DISEASES HOSPITAL MEETING

THE Hospital for Joint Diseases held its Annual Meeting in the Hospital Auditorium, New York, April 22.

Dr. S. S. Goldwater, F.A.P.H.A., Commissioner of Hospitals of the City of New York, addressed the meeting on "The City's Hospitals in Theory and Practice."

LECTURE BY DR. PARRAN

THE Hermann Michael Biggs Lecture this year was given by Thomas Parran, Jr., M.D., F.A.P.H.A., State Commissioner of Health, Albany, N. Y., on May 2, at the New York Academy of Medicine.

NATIONAL TUBERCULOSIS ASSOCIATION
MEETING

A TWO day health education meeting will be held for tuberculosis workers at Saranac Lake, June 21 and 22, 1935. Under the general heading, "Putting Our Knowledge to Work," there will be three round table sessions to discuss subjects as follows:

1. What Are We Trying to Do?
2. What Should Be Taught?
3. How Shall We Teach?

The leaders will be P. P. Jacobs, Harvey Dee Brown and Dr. Iago Galdston. The annual meeting of the National Tuberculosis Association takes place June 24-27.

CENSUS OF UNEMPLOYED

IT is authoritatively stated in Washington (April 1) that if the Employment Relief Bill pending before Congress is adopted, reasonably soon, it is likely that the Federal Relief Administration will allocate funds for a census of unemployment and population, to be taken about October 15. Write to your representatives in Congress and to the Federal Employment Relief Administration in support of the Census if the bill has not been adopted by the time this has been published A. W. H.

SCARLET FEVER THIS YEAR

THE prevalence of scarlet fever in the United States since the beginning of the present calendar year has reached a peak hitherto unattained. Reports received by the U. S. Public Health Service from state health officers record more than 8,000 new

cases for 47 states in 1 week. According to previous experience the peak for the prevalence of scarlet fever has occurred the first week or two in April.

The records above mentioned include only the reports during March. Reports regarding the prevalence of scarlet fever for April are awaited with interest.

GEORGE HOYT BIGELOW

COUNTRY wide search for Dr. George H. Bigelow, in which medical and public health journals took an active part, was brought to a close by the finding of his body in a reservoir in Framingham, Mass., on March 23, 1935. So is ended a brilliant career in public health, and the persistent hope of his family and friends that he would eventually return for further service in the field to which he had made such brilliant contributions.

A physician interested primarily in the social obligations of medicine, Dr. Bigelow early chose public health as the field offering the widest opportunities for service. From an auspicious start as Director of the Cornell Clinics he was called to Massachusetts Department of Public Health in 1923, and it was there during his 10 years as Deputy Commissioner and Commissioner of that department that he developed a quality of state health administration which has been an inspiration to health executives in all parts of the country. As Medical Director of the Massachusetts General Hospital, Dr. Bigelow was again looking toward the broader application of organized medicine to human needs, and his brief career there gave promise of new progress in hospital administration.

Substantial as Dr. Bigelow's contributions were in practically all the accepted fields of public health, he was perhaps best known for his pioneer work in chronic disease control. Believing that public need transcends any

arbitrary classification of disease, he accepted the challenge of a rising cancer toll, and through his vision, courage, and tireless energy, evolved a cancer program which points the way to further progress in that baffling field. That the establishment of such a program led to the awakened interest in cancer on the part of the medical profession, and a substantial increase in the admission of cancer patients to general hospitals all over the state is another tribute to his discrimination and the soundness of his judgment.

The full measure of a man is seldom in his accomplishments, and deep as is the imprint of Dr. Bigelow's work on the field of public health, it is by his personal qualities that he is best remembered. Gifted with a wit and lightness of touch which often masked his seriousness of purpose, his vision and steady courage were a never failing source of inspiration to his friends and associates. A leader who brought to public service a brilliance of mind matched only by his courage and devotion to human betterment, he has set a new beacon in the course of public health. Few in a long life have rendered greater service.

Dr. Bigelow has been a member of the American Public Health Association since 1923, and a Fellow since 1929.

HOUSING BILLS

INDIANA is the 11th state to empower its cities to create public housing authorities. The bill was passed by the Indiana General Assembly prior to its adjournment on March 11.

Alabama became the 12th state to pass such a law in March, when the State legislature approved public housing authorities legislation as recommended by the Legal Division of the Public Works Administration.

Connecticut, with a strong and well organized popular support for public housing legislation, has adopted a sub-

stitute for S. B. 403, which was a draft of the law submitted for approval and recommended by the Legal Division of the Public Works Administration. A shorter bill is now proposed. The shorter bill, which provides for the creation of local public housing authorities, will also set up a state housing board having supervisory control over the operations of the municipal authorities.—*Public Housing Progress*, April 15, 1935.

X-RAY AWARD OFFERED

THE David Anderson-Berry Gold Medal with a sum of money amounting to about £100 will be awarded in July by the Royal Society of Edinburgh to the person who in the opinion of the council has recently produced the best work on the nature of X-rays in their therapeutic effect on disease in human beings.

The secretary of the society is James H. Ashworth, D.Sc., 22 George Street, Edinburgh, 2.

CANCER SURVEY

THE prevalence of cancer in rural areas in Michigan will be determined in a survey to be undertaken by the Michigan State Department of Health under a grant from the U. S. Public Health Service, to include only full time county or district health departments.

COSMETICS REGISTRY LAW

PERMITS must be obtained from the State Department of Health in Maine for the marketing in Maine of cosmetics and beauty culture equipment, under a newly enacted law. This law supplants legislation enacted in 1934 which was invalidated by a Federal Court injunction on the grounds that it regulated interstate commerce.

The new law does not require the submission by manufacturers of their

formulas, or their obtaining a permit for variations of a product because of differences in shade, color, or odor. Household and toilet soaps also are exempted from the cosmetic classification unless they are represented as preparations for the treatment of disease.

Registration costs are fifty cents for each sample. The law also authorizes refusal of registration in instances where products may be regarded as injurious to health.—*Printers Ink*, Apr. 18, 1935, p. 78.

CELLAR HOUSING

FULLY 10,000 of the Harlem (New York) citizenry—the families which cannot pay the high rents nor obtain relief—now live in cellars; dark, damp, cold dungeons, in squalor worse than that of the Arkansas share-croppers.—Rev. A. Clayton Powell, Jr., *Public Housing Progress*, April 15, 1935.

NEW HEALTH OFFICERS IN KANSAS

THE Kansas State Department of Health announces the following appointments of County Health Officers:

Dr. Ernest J. Beckner, Goodland, Sherman County

Dr. Frederick E. Dargatz, Kinsley, Edwards County

Dr. Charles E. Gaston, Frankfort, Marshall County

Dr. Francis D. Kennedy, Norton, Norton County

Dr. James H. A. Peck, St. Francis, Cheyenne County

Dr. William F. Schroeder, Newton, Harvey County

MARYLAND CHILDREN EXAMINED

A TOTAL of 9,749 children were examined in the child health conferences sponsored by the State Department of Health of Maryland in 1934. Of these 2,490 were free from conditions in need of correction; 1,465 were underweight or gave other evidence of malnutrition; 3,492 needed dental attention. Unfavorable conditions of the

lungs were noted in 59, and of the in 245.

In the 651 conferences held, 417 communities were represented. Medical treatments were not given, but children needing care were referred to their own physicians and prompt correction was urged.

ONONDAGA COUNTY

THE Onondaga Health Association of Syracuse, N. Y., has published a pamphlet in the interest of a County Health Department for Onondaga County. The pamphlet carries a study of the present services and proposed budget made by Dr. Philip J. Rafle, District State Health Officer. After analyzing the effect of the tax rate in each municipality and extending the figures to show the change in the tax burden on a small home, the following paragraphs are added which visualize the relative size of per capita costs in a fashion which may be useful to other health departments:

Four cents will buy 2 postage stamps. 10 cents will buy 1 cigar or 1 package of bobby pins. 15 cents will buy 1 movie ticket. 25 cents will buy 2 packages of cigarettes. 50 cents will buy 1 lipstick or 1 box of candy.

. . .
A modern, centralized administration of public health in place of the present obsolete set-up, would give the people in towns and villages greatly increased protection against preventable sickness and death. . . .

Taxpayers would secure 50 per cent State aid and other economic gains. . . .

These benefits can be had for the price of $\frac{1}{4}$ mile of gravel road.

DECENT SHELTER

WE must recognize in this country that every person has a right to decent shelter and that society owes to every child the opportunity to enjoy the health producing sunlight and fresh air and recreation which the slums deny.—Senator Robert F. Wagner, *Public Housing Progress*, April 15, 1935.

A.N.A. OFFICERS

THE Board of Directors of the American Nurses Association, meeting in New York in January, appointed Alma Ham Scott, of Indiana, Director at Headquarters, and Ella Best, of Illinois, Associate Director.

The Board also elected these nurses to the new Board for the *American Journal of Nurses*:

President, Stella Goostray, Boston, Mass.; Secretary, Julia Stimson, Washington, D. C.; Treasurer, Anne L. Hansen, Buffalo, N. Y.; Members: Katharine Densford, Minneapolis, Minn.; Eugenia Kennedy Spalding, Washington, D. C.; Emilie Sargent, Detroit, Mich.; Elizabeth Soule, Seattle, E. F. M.

INTERNATIONAL HOUSING CONGRESSES

THE first of the two international congresses on housing to be held this summer will take place in Prague, Czechoslovakia, June 23-26. This formal meeting will be followed by a study-tour to Hradec Kralove, Zlin, Brno, and Bratislava, for the inspection of the various types of modern housing developments to be found in these communities.

This Prague congress and tour are under the auspices of the International Housing Association, and will be of particular value to all students of the housing problem, who are invited to attend.

The announced topics for formal discussion are: Slum-clearance and elimination of unsanitary dwellings; Technical installations and equipment of small dwellings; and Measures for rehousing the unemployed and part-time workers.

The Fourteenth International Housing and Town Planning Congress will be held in London from July 16 to July 20. Discussion during the 4 days will be under three general heads: Rehousing the people; Positive planning; and

Planned rural development and the preservation of the countryside. Bearing on these three topics, papers will be read to the congress by housing experts from most of the countries in western Europe.

On the afternoons of July 16 and 19, visits have been arranged to the housing schemes of the London area. An all-day visit to the Letchworth and Welwyn Garden cities will be conducted on the 18th. At the conclusion of the congress, those wishing to examine further the English re-housing developments can take a 5 day conducted tour to the cities of Harrogate, York, Leeds, Manchester, Bolton, Liverpool, and Birmingham.

The London congress and the tours are all being arranged under the auspices of the International Federation for Housing and Town Planning.—*Public Housing Progress*, April 15, 1935.

NARCOTIC FARM OPENING POSTPONED

THE opening of the First Narcotic Farm at Lexington, Ky., was expected to take place about April 1. Because the building operations have not progressed as rapidly as had been expected, it has been necessary to postpone the opening of this institution. It is probable that it may be June 1 or later before patients are admitted.

MORE REASONS FOR PASTEURIZATION

DR. S. J. Crumbine's report indicated that 45 milk-borne epidemics had occurred during 1933 in 24 states; according to reports of state health officers, 44 of these epidemics having been traced to raw milk and one to raw cream.

Referring to undulant fever, Dr. Crumbine said:

The four epidemics of undulant fever reported for 1933 and none for 1932 would not seem to indicate a wide distribution of the disease or that it constituted an important health problem in relation to milk. But when we consider the 1,502 cases and 71 deaths re-

ported by the U. S. Public Health Service occurring during the fiscal year 1933, and the other large number of unreported and unrecognized cases that probably occurred, it must be admitted that undulant fever is a health and economic problem of major importance. Infected dairy herds are widely distributed over the United States and Canada, the rate of infection running from 5 to 50 per cent or higher.

If there were additional reasons needed for universal pasteurization of milk, the increasing menace of undulant fever would provide them.

—*Colorado Med.*, 32, 2:115 (Feb.), 1935.

PWA HOUSING PROGRAM

MANY people think of the problem of slum clearance and better housing as one applicable only to the large cities, and have disregarded the need for such work in our smaller towns and villages. The entire question of housing is a problem that concerns not only the large metropolitan areas, but every community in the country. We must look to these smaller areas for the support of the housing program throughout the nation.—B. M. Pettit, Housing Division, Public Works Administration, *Public Housing Progress*, April 15, 1935.

PERSONALS

H. E. KLEINSCHMIDT, M.D., Fellow A.P.H.A., Director of Health Education of the National Tuberculosis Association, sailed March 28 to make a study of exhibit building in Germany, the Netherlands, and Austria, by courtesy of the Oberlaender Trust of Philadelphia.

EMERY R. HAYHURST, M.D., PH.D., F.A.P.H.A., is Chairman of the American Committee for the Section on Industrial Diseases, of the Seventh International Congress on Industrial Accidents and Diseases, to be held in Brussels, Belgium, July 22–27, 1935.

WILLIAM B. WELLS, M.D., F.A.P.H.A., of Riverside, Calif., has retired as Health Officer of Riverside City and County on account of ill health. He has been succeeded by Dr. Wendell A. Jones, of Riverside, member A.P.H.A.

RUTH HOULTON, R.N., F.A.P.H.A., a former supervising nurse for the Minnesota Department of Health, and more recently general director of the Minneapolis Visiting Nurse Association, took her place on the staff of the National Organization for Public Health Nursing in March. This addition was made possible because the Organization had just received a special gift from the Commonwealth Fund.

DR. ALLEN C. KRAMER, of Tulsa, Okla., has been appointed Health Officer of Tulsa County, to succeed Dr. Thomas W. Stallings.

CHARLOTTE J. CALVERT, M.D., of Madison, member A.P.H.A., supervisor of the Bureau of Child Welfare of the State Board of Health of Wisconsin since 1929 and a member of the staff since 1925, retired to private life March 1.

DR. WALTER A. STERNBERG, of Mount Pleasant, Iowa, has been appointed a member of the State Board of Health of Iowa, succeeding Dr. Nathaniel M. McKittrick, of Burlington, resigned.

DR. VONANDO G. LOGAN, of American Falls, Idaho, has been appointed Health Officer for Power County, Idaho.

ELDRED V. THIEHOFF, M.D., Fellow A.P.H.A., formerly Acting Director of the Cleveland Child Health Association, has been named Director of Health District No. 7, comprising Gladwin, Arenac, and Clare Counties, with headquarters at Gladwin, Mich.

ETHEL WIGMORE, Librarian of the National Health Library, National Health Council, 50 West 50th Street, New York, will become Librarian of the School of Nursing Library, Bellevue Hospital, on April 15. She has been with the Council for 9 years, and Librarian for 3 years. She was formerly Librarian of Peiping Union Medical College, Peiping, China.

CHARLES A. NEAFIE, M.D., member A.P.H.A., formerly Health Officer of Pontiac, Mich., has been reappointed to that position, filling the vacancy caused by the resignation of Hubert M. Heitsch, M.D., member A.P.H.A.

HUBERT M. HEITSCH, M.D., of Pontiac, Mich., member A.P.H.A., has resigned as Director of Public Health of the City of Pontiac, to accept a position on the medical staff of the new combined Chevrolet and Fisher Body plant at Baltimore, it is stated.

DR. FREDERICK McD. HARKIN has been appointed Health Officer of Marquette, Mich., to succeed Thurman R. Laughbaum, M.D., member A.P.H.A., resigned. Dr. Harkin held the position in 1893.

DR. WILLIAM M. BRIEN, of Orange, N. J., member A.P.H.A., has resigned as First Assistant Medical Examiner of Essex County, to become Health Officer of Orange. His successor is Dr. George P. Olcott, Jr., of East Orange.

HELEN PECK, until recently director of the Infant Welfare Society in Minneapolis, is now Chief Consultant in Public Health Nursing, State Department of Health, Boston, Mass.

RUTH E. STOCKING, M.D., has been appointed to the staff of the Bureau of Child Hygiene and Public Health Nursing of the State Department of Health, Lansing, Mich., to take the place of Dr. Goldie Corneliuson, resigned.

DR. ROY L. CLEERE, of Denver, Colo., has been named a member of the

Colorado State Board of Health, succeeding Samuel R. McKelvey, M.D., of Denver, member A.P.H.A., who had served on the Board since 1911.

DR. HARRY B. SMITH has been appointed Superintendent of Health of West Hartford, Conn., succeeding Dr. Theodore F. Foster, member A.P.H.A., resigned.

HUGH B. SENN, M.D., of Newberry, S. C., member A.P.H.A., has succeeded Guy G. Lunsford, M.D., of Millen, member A.P.H.A., as Health Officer of Jenkins County. Dr. Lunsford resigned to become chief of the Division of County Health Work of the State Department of Health.

DR. GIDEON DOUGLAS WILLIAMS, of Lake Providence, La., Director of the East Carroll Parish Health Unit, has been appointed in charge of the Ouachita Parish Health Unit, succeeding Dr. John W. Williams, of Monroe, member A.P.H.A., who resigned to become Health Director of Asheville, N. C.

DR. JOHN C. MCGUIRE, at times in charge of county health departments in Kentucky, has been named full-time Director of the Copiah County Health Department, succeeding Dr. James T. Googe, member A.P.H.A., who recently resigned to become Assistant Health Director of Florida.

DEATH

LUCY MINNEGERODE, Superintendent of Nurses of the U. S. Public Health Service, died in Alexandria, Va., March 24. She was one of the first Red Cross Nurses to volunteer for overseas duty after the outbreak of the World War. She was decorated by the Czar of Russia for her nursing services at Kief on the Russian front in 1915. Later she was awarded the international Florence Nightingale Medal. She was a graduate of the Bellevue Hospital Nursing School, New York.

MEDICAL TOUR TO RUSSIA

IT is announced that rates have been lowered considerably on the Medical Tour to the U.S.S.R. and the 15th International Physiological Congress, under the sponsorship of Dr. James S. McLester and Prof. A. J. Carlson. Individual itineraries can be arranged. Write the World Exchange, 203 So. Dearborn St., Chicago.

CONFERENCES

- May 4, 5, Spring Meeting of the Michigan Branch of the American Student Health Association, Battle Creek, Mich.
- May 6, 7, 14th Annual Massachusetts Safety Conference, Boston, Mass.
- May 6-10, Annual Convention of American Water Works Association, Cincinnati, Ohio.
- May 12, Mothers Day.
- May 14, 15, 19th Annual Meeting of the Central Atlantic States Association of Dairy, Food and Drug Officials, Richmond, Va.
- May 18, Child Health Day.
- May 20-22, Tenth Annual Meeting of the American Association for Adult Education (66 East 42 Street, New York), Milwaukee, Wis.
- May 24-25, Spring Meeting of New York State Sewage Works Association, Poughkeepsie, N. Y.
- May 31, June 1, Tenth Annual Conference, New England Health Education Association, Cambridge, Mass.
- June 3-5, Twenty-Fourth Annual Meeting, Canadian Public Health Association, in conjunction with the Ontario Health Officers' Association, Canadian Tuberculosis Association, and Canadian Social Hygiene Council. Royal York Hotel, Toronto.
- June 4-9, Annual Meeting, Royal Institute of Health, Harrogate, England.
- June 12, 13, Annual Meeting, Academy of Physical Medicine, Atlantic City, N. J.
- June 9-15, National Conference of Social Work, Montreal, Canada.
- June 10-14, Annual Meeting of the American Medical Association, Atlantic City, N. J.
- June 14, 15, Meeting of State and Provincial Health Authorities, Atlantic City, N. J.
- June 17-19, Ninth Annual Iowa Conference on Child Development and Parent Education, Iowa City, Iowa.
- June 17-19, Semi-Annual Meeting, American Society of Heating and Ventilating Engineers, Royal York Hotel, Toronto, Ont., Can.
- June 19-22, Eighth Health Education Conference of the American Child Health Association, Iowa City, Iowa.
- June 24-27, Annual Meeting of the National Tuberculosis Association, Saranac Lake, N. Y.
- June 24-29, Summer Meeting of the American Association for the Advancement of Science and Associated Societies, Minneapolis, Minn.
- July 1-3, Sixth Annual Meeting, Western Branch American Public Health Association, Helena, Mont.
- July 15-20, Royal Sanitary Institute Health Congress, Bournemouth, England.
- July 22-27, Seventh International Congress on Industrial Accidents and Diseases, Brussels, Belgium.
- July 23-27, International Congress on Life Assurance Medicine, London.
- July 31-Aug. 3, Annual Meeting of the American Dental Society of Europe, London.
- Aug. 10-17, Meeting of Health Section of the World Federation of Education Associations, Oxford, England.
- October 7-10, Sixty-fourth Annual Meeting of the American Public Health Association, Milwaukee, Wis. Headquarters: Hotel Schroeder.
- October 14-18, 24th Annual Safety Congress, National Safety Council, Inc., Louisville, Ky.

Serving the Public for Health*

HENRY F. VAUGHAN, DR.P.H., F.A.P.H.A. (*Life Member*)

Health Commissioner, Detroit, Mich., and Member of Board, W. K. Kellogg Foundation, Battle Creek, Mich.

IT is the obligation of all public health administrators to provide, in an efficient and economical manner, the means of health protection, and at the same time stimulate an interest in the promotion of positive health habits. There are many health officers who will agree with the statement that the participation of all physicians and dentists in the public health and medical services of the community will result in advantages to the individual, the public, and to the health service of the community. There is existent in every area, whether urban or rural, a potential reservoir of medical knowledge and service which can be activated to serve the local health needs. By stimulating these resources, which have lain dormant among the practising physicians and dentists, the spirit of health education can be made to permeate every home and provoke a response on the part of the conscientious parents so that they will do their share to secure modern health benefits for their children.

It is my intention to discuss certain

studies which have been carried on during the past several years in the administrative field for the purpose of increasing the active participation of practising physicians. There is nothing in these studies which detracts from the essentialness of a properly organized local public health service—preferably a whole-time health service with a full-time health officer assisted by adequately trained health educators, public health nurses, technicians, and other personnel which we all recognize as essential to modern health service. Such a health department should be blessed with reasonable financial support and should be organized with the political independence repeatedly recommended by the American Public Health Association, and so admirably emphasized by the Committee on Public Health Organization of the White House Conference on Child Health and Protection. It is axiomatic that the first essential of a program of medical participation is the existence of a properly organized modern public health department.

It is equally important to bear in mind that a program of medical participation should not be limited to one line of approach. It should not be considered merely an effort to secure the

* Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

protection of all susceptible children against diphtheria, nor should it be an undertaking restricted to the search for the early case of tuberculosis. It should be recognized that the program is broad in its conception and in its application. It should embrace the gradual incorporation into private medical and dental practice of all those services of a preventive character which, in the final analysis, are available only at the hands of the duly licensed professional man. Diphtheria protection has frequently been the first objective in the program, but the administrator should remember that the same principles of procedure apply to smallpox and typhoid fever immunizations; to the provision for the annual health examination; to the search for the early signs of departure from normal health which may indicate tuberculosis, cancer, and heart disease; to the diagnosis, treatment, and control of syphilis; to the provision for health examinations and the promotion of health education among those groups who because of their occupation may prove a particular hazard to public health; and especially to the general promotion of hygienic living habits and the relief of the individual from the physical and mental handicaps which may, if neglected, deprive him of the full enjoyment and maximum utilization of his life.

The studies in Michigan and elsewhere have unfortunately become known primarily as an effort to provide diphtheria immunization, in spite of the fact that from the very beginning we have repeatedly emphasized that this is a program which we hope will ultimately provide a well-rounded health service at the hands of the family physician in coöperation with the health department. The by-products which will gradually develop are more valuable than the initial objective.

It should also be borne in mind that a program which involves the gradual

transfer to the physician's office of some of these services, which in the past have been maintained directly by the health department in clinics, health centers, and dispensaries, cannot be placed in full operation in a short time. It is not a program of a few weeks or even a few months; it is a program of several years. It involves a change of attitude on the part of the administrator, the physician, the organized medical society, and the public. It is not a program which is revolutionary in character. It is the gradual evolution of a procedure embracing the practice of preventive as well as curative medicine by the family physician.

The program involves a three-cornered understanding between the professional group, the local health agency, and the public. The first essential is to prepare the medical profession. It is both reasonable and practical that the professional group should be represented by its organized society, usually the county medical society, which may function through its duly authorized public health committee, this committee's action regularly reviewed and approved by the council and officers of the society. There should be recognition on both the part of the medical society and the health department that they have a common objective—to provide adequate and efficient service for the public. The holding of regular periodic meetings by the public health committee at which there is generous representation from the health department staff, not only establishes a close harmonious relationship but provides a workable administrative unit. The health department should serve as the executive unit to place in operation the plans as developed and adopted by both agencies. Neither the county medical society nor the health department can function with maximum efficiency without the support of the other group.

The medical profession must be pre-

pared in two respects: first, with regard to the group plan, and second, with respect to the technics of the services which are to be rendered. The individual physician must be willing to subscribe to a form of procedure adopted by the organized medical group. He must agree to prepare himself to render the type of service to which the public is entitled; he must understand the value of diphtheria toxoid, the significance of the Schick test, the desirability of giving the tuberculin test and its relationship to the roentgenological examination of the chest, and the health examination. The physician should agree to establish the services in his own office at such times and accept such other arrangements as are incorporated in the group plan.

At the very beginning steps should be taken to acquaint all physicians with the purposes of the program. Failure to do so will result in misunderstandings and in the loss of public confidence. It would be disastrous to urge a parent to send his child of susceptible age to a coöperating physician for diphtheria protection if such physician were unconvinced of the value of prophylactic treatments or if he were not familiar with the technic involved. Months of preparation of the profession may reasonably precede any effort to stimulate public interest.

In the Michigan studies three methods of preparing the physicians have been followed. Postgraduate conferences on preventable diseases designed to attract the physician because of his interest in clinical medicine have been developed and utilized to establish an interest in specific health services. Such conferences have been well attended by the members of the organized medical profession. There is little difficulty in reaching physicians who are wont to attend medical meetings, who belong to the district societies, or who are attached to hospital staffs. There

are, unfortunately, some physicians in every community who rarely if ever attend medical meetings, and in order to reach these the services of a medical coöordinator have been utilized—a physician representing both the health department and the county medical society—who visits the practising physician in his own office, painstakingly outlines the group plan, and demonstrates the services to be rendered. As the program has gradually evolved and expanded from one of mere diphtheria protection into smallpox vaccination, periodic health examinations, and tuberculosis case finding, each added service has been carefully explained and outlined to the coöperating physicians, both in group meetings and by individual visits. The plan has also been explained to the senior students in the medical schools in order that as these new physicians take up their work in the community they may be well informed concerning the program of medical participation. Diphtheria protection was undertaken as the first objective in the Detroit studies. Since 1928 some 1,100 physicians have co-operated, 700 of whom responded when the plan was outlined by letter through the county medical society, and 400 of whom were reached through the medical coöordinator.

After the profession is thoroughly conversant with the group plan the problem resolves itself into one of bringing in contact with the qualified and prepared physician the child of susceptible age who is in need of the preventive service. This requires an application of the tools of health education. The parent must be stimulated to accept his obligation and to secure for his children the services which the coöperating physician is ready and willing to provide in his own office.

Two methods of health education have been employed. Through popular health instruction, which involves all

recognized means of utilizing the printed and spoken word, we were able to secure the protection of about 1 child in 5. We used the radio, radio dramas, billboard advertising, streetcar and motorbus placards, literature distributed through the schools, and we enjoyed the full support of the press with feature stories and editorials. The Health Education Division of the Detroit Department of Health incorporated this program in its routine contact with school children, parents, and the public generally. We realized, however, that to secure the protection of 20 per cent of the children would not suffice. We, therefore, adopted the procedure of reaching the parent through individual health instructions. We have used the public health nurse as the family health adviser.

The public health nurse who has received special training in health education and who at the same time is conversant and sympathetic with the attitude of the medical practitioner, becomes a very potent connecting link between the parent, the child, and the family physician. It is largely through her efforts that the newer knowledge in preventive medicine can be presented to the average citizen. In Detroit by focusing her educational attention upon the parents of the 6 months old infant, she has materially increased the number of children protected. Now nearly 1 out of 2 of all infants born are being protected before they reach their first birthday.

The W. K. Kellogg Foundation has joined with the people who reside in 5 typically rural counties in southwestern Michigan in establishing full-time county health departments with adequately trained personnel. The health officers are physicians who have specialized in public health work, and the public health nurses, in addition to being registered nurses, are graduates in health education from recognized col-

leges. An unusually close relationship has been brought about in these communities between the medical profession, the dentist, the family health adviser, school teachers, ministers, newspaper men, social workers, and other groups and individuals who have a special interest in health education. Postgraduate courses for these rural physicians and dentists have been given in Chicago, Detroit, and elsewhere. Public health institutes have been held for school teachers, ministers, social workers, and health officers. The underlying motive has been to bring together in one compact unit the various groups who have a common interest, that is, the promotion of child health. At no time in the development of public health work has there been greater need of coördinating and cementing the common interest which, if not activated, remains dormant in the various educational and professional groups which because of training and experience may readily adapt themselves to health education.

We would not urge or recommend a standardization of procedure with the thought of its adoption for all parts of the United States. Rather is it fortunate that there are plenty of opportunities to experiment locally in counties and states, and from the experience of others we may choose and adopt methods in medical participation which appeal to our local conditions. It may be of interest, however, to outline a few of these local experiences. In Detroit, under the terms of a program adopted jointly by the Wayne County Medical Society and the Detroit Department of Health, some 1,100 physicians have agreed to carry on certain public health procedures in their own offices at specified hours. Each physician has indicated the days and hours when he will be available to provide diphtheria immunizations, further agreeing that at these special hours he will charge \$1 for each dose of the immunizing agent, and.

the health department has agreed to reimburse the physician at the rate of \$.50 for each dose in those instances where in his judgment the parent is unable to pay. There is, therefore, in effect an assurance plan, one which assures the child the type of preventive service to which he is entitled, and further assures that the service is available to all at a reasonable cost, irrespective of ability to pay.

This same general arrangement is in effect in Allegan, Eaton, Barry, and VanBuren Counties in Michigan where the W. K. Kellogg Foundation is coöperating and where under rural conditions it has been found practical to transfer the diphtheria prevention treatments from school clinics to the physician's office.

In Charleston, W. Va., the Health Officer, in coöperation with the Kanawha County Medical Society, confronted with an outbreak of diphtheria, determined to increase the percentage of children protected through a plan of medical participation. There are some 110 physicians in Charleston, of whom 88 participated. Conferences were first held with the city officials, the school officials, the health officer, and the members of the medical profession, at which the program was fully outlined and definite instructions given. After preparing the medical group, the education approach was directed toward the public and through the schools, by radio, through newspaper stories; and through other recognized health education channels public support and confidence were sought. There were no funds available with which to pay the physicians for service rendered to indigents. The local doctors felt, however, that the fundamental principle of having the work done in the physician's own office was so important that they would contribute their time to those children whose parents could not afford the modest fee of \$1. Four hours per week, 2 on

Thursday and 2 on Saturday, were designed by the 88 coöperating physicians as hours at which the service would be rendered. This work was carried forward so effectively that the percentage of preschool and school children protected against diphtheria was doubled within a period of a month. The number of protected children was increased to 50 per cent of the school group as well as 50 per cent of the preschool group, and diphtheria disappeared from Charleston.

Of special note is the fact that 52 per cent of the immunizations were paid for by the parents. Even had the local physicians not benefitted by this increase in revenue, there was no doubt in their minds that the program contained certain tangible by-products which eventually would be profitable not only to them but to the public and to the local health department. The physician who is alert to his responsibility and to the opportunity afforded by many new contacts established in his private practice, will endeavor to interest the child's parent in other health promotion services such as the periodic health examination, the recognition and removal of physical and mental handicaps, and the establishment of a friendly health consultation service between the physician and the family. This will unquestionably do much to overcome the existing influence that many cultists and pseudo-medical practitioners have established in the public mind.

There is nothing new or even novel in this program of medical participation. Many physicians and health officers have for years discussed the advantages of a plan whereby the professional man in private practice plays a more intimate part in the public health program. Recent experiences are but the application of recommendations which are almost universally acceptable. Instead of passively declaring that the physicians will not work with the health

department, the health officers have cultivated the medical profession and extended their facilities to encourage a coöperative plan.

While there has been a diminution in the need of clinics operated under health department auspices, it should be borne in mind that in no case has any service been discontinued until there has been created an effective substitute which will give service of as high a character or better service than that previously rendered. Specifically, the tuberculosis and venereal disease clinics in Detroit have not in any manner been curtailed, although an effort is being made in certain selected areas to transfer the services to the physician in private practice.

In one area during the past 2 years, all indigent cases of syphilis have been returned to the physician's office, the health department providing the necessary salvarsan and other drugs, carrying on the educational program and policing the patient in order to make sure that he remains under the care of his physician during the infectious stage of the disease.

In another area containing more than 300,000 people the coöperating physicians are examining in their own offices the known intimate contacts to reported cases of tuberculosis, are giving the tuberculin test to children of selected age groups and, in coöperation with the organized roentgenologists, are providing chest examinations for the positive reac-

tors. In this particular study no funds have been used to compensate physicians for service rendered to indigents unless the latter are on the public welfare rolls. In Albany the county medical society and health department were successful in securing an appropriation with which to establish a tuberculosis case finding program for all pupils entering the senior high schools, the physicians being paid by the city for service rendered to indigents.

The program places particular emphasis upon the prevention of disease. We all recognize that prevention is cheaper than cure. The program maintains that cordial direct relationship between physician and patient which has existed for so many centuries with satisfaction to each.

Can we not visualize a medical practice of the future wherein every qualified physician will maintain a disease prevention service and a health education center in his own office? where he will function as a disseminator of health knowledge and thus make available to the public maximum utilization of the products of our scientific laboratories and centers of medical research? Each coöperating physician will in fact become a deputized agent of the community health service. It is in this manner that we may look forward with confidence to continued progress in the elimination of needless sickness and premature death.

Serving the Public for Health^{*}

J. L. POMEROY, M.D., F.A.P.H.A.
County Health Officer, Los Angeles, Calif.

PUBLIC events during the worldwide depression in relation to health service for the people command serious attention from those of us engaged in administering official public health work throughout this continent. There are forces both within and without the ranks that may mean profound change in the future of our public health organization. The very structure of government itself is under fire. There is no doubt in my mind that the problem is fundamentally economic, but there are many conflicting interests and philosophies that exert a tremendous influence. Every health department has suffered the impact of budget cuts and of pressure from specialized interest all of which makes the question of the future of great moment.

Health service for the people includes not only preventive measures and sanitation in its broadest sense, but also, whether we administer the service or not, curative medicine. Community sanitation has to a large extent solved the problem of our major communicable diseases so prevalent a century ago, such as typhoid fever, yellow fever, plague, and similar infections. Diphtheria and smallpox may no longer be considered serious problems, since the means of control are well established. On the other hand, the respiratory in-

fections, nutritional disorders, dental infection and decay with its attendant focal infection, the increasing breakdown of the mental and nervous system, the growing mortality from cancer and heart disease, the terrific toll from accidents and the preventable diseases attendant on childbirth—these are a challenge to the public health departments of the United States.

In spite of tremendous effort put into the program of health education, we must admit that we have barely scratched the surface. The American people spend on an average of 125 million dollars¹ annually in support of the cultists and irregular practitioners of medicine, in addition to probably 360 million dollars for patent medicines and quackery. This situation is largely the result of the *laissez faire* policy or the so-called rugged individualism so frequently advanced as the solution of our many difficulties.

Much confusion exists in the minds of *some* members of the medical fraternity in regard to the newer phases of our public health program. The dictum from certain quarters that health officers must be concerned only with mass education, and that personal services to individuals must be omitted, shows a misunderstanding of modern public health procedure. Public health education itself has distinct and specific limitations. The most successful campaigns of health education, in my opinion, rest partly upon individual health service.

^{*} Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

IMPORTANCE OF INDIVIDUAL

With the discovery of the importance of carriers of disease, coupled with the revelation of specific methods of spread of infectious diseases, together with the progress made in early diagnosis, notably the X-ray in tuberculosis, the importance of the individual citizen in our campaign against disease and sickness has become paramount. We cannot X-ray a community or immunize a municipality. A single unknown carrier of an infectious disease may infect hundreds of other persons.²

In our campaign of case finding and early diagnosis of tuberculosis in the Los Angeles County schools, we have insisted in all positive tuberculin reactors that the parent be present to receive the interpretation of the test. During the past 3 years 16,000 children have been tested and in 85 per cent of the positive cases the mother has been present. This experience demonstrates that action is always dependent upon interest and upon motivation; without demonstration, public health education, in my opinion, is largely sterile. Many individuals demand demonstration rather than argumentation.

In California all county health officers must be graduates of a medical college of good standing and repute. The majority of the cities also require a doctor of medicine. The question of medical leadership certainly cannot be fairly raised under these conditions. Let us turn to the situation in regard to the practice of medicine in California. A recent survey shows that in Los Angeles County, besides 3,918 M.D.'s, there were 4,218 persons practising medicine who belonged to the cultists. These persons include 1,440 chiropractors, 927 osteopaths, 550 optometrists, and 101 midwives and drugless healers. Also, there are 1,200 known Christian Science practitioners with probably as many more unknown who, to all intents and purposes, are

engaging in the practice of medicine. Placing the average income of each of the 4,218 persons at \$2,500 a year, over 10 million dollars annually are diverted which should go to the regular medical profession. Probably almost as much money is spent in nostrums and patent medicines, the amount certainly reaching into millions of dollars. If means could be found to divert the money spent in nostrums, quackery, and cultism to the medical profession, I estimate that it would increase the annual income to every doctor in Los Angeles County somewhere between \$3,000 and \$5,000.

PUBLIC HEALTH SERVICE NOT LIMITED
TO PAUPERS

We approach the problem of the medical profession in relation to health departments with a sense of profound appreciation and generous gratitude for the service rendered by the physician. The services of well trained medical men are fundamental in the cause of community health. Their rewards are notoriously low compared to the costs of training and service to the public. We are inclined to question, however, the present tendency to curtail the so-called personal services of health departments and parcel out these functions through a process of financial subsidy. We propose to show that the difficulty cannot be met in this manner; that the cost is prohibitive; and that the risk to the health department from reduced public support is very great indeed.

Let me speak first of the idea so generally prevalent among medical men that the personal services of the health department should be limited to the pauper class. In this respect I wish to quote from the address of former President of the Association, Louis I. Dublin:

As in the field of medicine, public health work makes no distinction between rich and

poor, between high and low. The prevention, like the cure of disease, knows no level. The method and spirit of this movement maintains the finest of democratic traditions and holds out the largest promise for a glorious future. It is this phase of health service that should give purpose and direction to our professional work.³

May I also state that President Hoover in his White House Conference address likened the functions of preventive services in health departments to those of education. In fact, in reviewing the history of the public schools in America, I find almost the same arguments used today against the free preventive clinic in health departments as were used by the opponents many years ago during the struggle for our present public school system in America. Certainly if education, as practically everyone admits, is the very foundation of democracy, then what shall it profit a child to secure an education, if he die of preventable disease in so doing.

SURVEY OF OPINION

The writer presented these problems to some 30 leading health authorities throughout the United States during the last year, and is happy to say that the majority of the opinion was that the health department is *not* concerned with the pauper alone, but by virtue of its legal powers it is the *duty* of the department to serve the entire people.⁴ It was generally conceded that the economic problem of the medical profession is a phase of the general economic difficulties of our entire social structure, coupled with the need for group purchase of medical care, and the elimination of unfair competition from cults. The conclusion was obvious that the parceling out of the so-called personal health functions such as immunization by the payment of fees to private physicians would not solve the economic problem of the physician but might result in further curtailment of health budgets by the people.

Some \$3,000 raised by individual contributions from Health Department employees was expended in a 6 weeks campaign in the district of Belvedere on a diphtheria immunization program, in which all patients were routed to the private doctor's office.⁵ The doctor collected whatever he could but the Health Department furnished the toxoid. About 500 immunizations were secured and it was discovered that less than half of the population had a regular M.D. for a doctor. A considerable number of citizens criticised the health department for not doing the work. When the program was opened up on a free immunization performed by the health department, 3,000 were done in less than 2 months, at an expense of \$.41 per child. In view of the most insistent demands of economy in public government, we are scarcely justified in paying \$2.50 to \$6.00 to secure an immunization of a child when this service can be rendered by the department for less than \$.50.

It is the duty of the health officer to take such measures as are necessary in the State of California to prevent the spread of communicable disease. In view of the very evident obstacles in this method of medical participation, should any health officer endanger his entire program in pursuing a course which is apt to be opposed by the people?

UNOCCUPIED TERRITORY

The situation of the medical profession is also very largely a question of unoccupied territory. We grant that if the medical profession practised in all degrees the procedure of modern health departments in its well baby conferences, in immunization, in early diagnosis of tuberculosis, etc., there would be little need, indeed, for much of the activity of the health departments. The truth lies, however, in the fact that during *good* times few physicians, except

specialists, make a routine procedure of these methods. Many examinations held by the Civil Service Department of Los Angeles County during good times for positions paying around \$3,000 a year, found few candidates among our medical confrères. Since 1929, however, the health department has had frequent demands that it cease entirely its clinical services and at the same time that it expend thousands of dollars in employment of private physicians. Is there any reason to hope that these phy-

sicians who now clamor for public health work will retain their interest when good times return? Shall we disrupt an organization which has taken years to build only to have the task of reconstructing it in a short time?

GROWTH OF CULTISTS

What is the reason of the growth throughout the United States of the cults? It is a curious fact that, coupled with the curtailment of the opportunities for medical training begun some 20

years ago by our regular medical schools, there has been a tremendous and far-reaching increase of the cults. Thousands of young men denied the opportunity to study regular medicine have been lured both by the lower costs of chiropractic and similar training and also by the fact that through advertising methods an effective public demand for these services could be created. The growth of religious healing was undoubtedly in part due to the failure of the medical profession to recognize the needs and the opportunities in the field of mental healing. The psychiatrists have pointed this out many times. The growth of osteopathy and chiropractic is undoubtedly partly due to the neglect of the medical profession to use physiotherapy and similar methods in treating their patients. Here again we have the problem very largely of unoccupied territory.

It has been recently proposed as an aid to the solution of the economic difficulties of the physician that the number of graduates from our medical schools be restricted, and hence the number of licensees would automatically be cut down.⁶ It has been stated that there has been an annual excess of over 1,500 practitioners each year in the United States over and above losses through deaths. If Los Angeles County with a population of approximately 2,300,000 can support not only 3,918 practitioners of medicine but also 4,218 cultists, does this show that there are too many doctors? Will the cutting down of the number of regular M.D.'s not be accompanied by a corresponding increase in the cultists? In my opinion, the truth of the matter lies in the fact that we do not have too many doctors but an unequal distribution throughout the United States of physicians and medical facilities in general. Means must be found through proper basic science laws to curtail the growing grasping inroads of the cults. We must

look to these factors primarily as one of the important elements in the economic difficulties of the physician. Certainly the answer is not to be found in curtailment of the program of the health department.

THE HEALTH CENTER

The newer aspects of the technic of public health administration brought about the development of the health center. There is no doubt that the hospital has been of enormous benefit not only to the patient who receives treatment therein but as a remarkable visual education to the public of scientific medicine at work. The public school system advanced tremendously through the abandonment of the ungraded little red school house of the past and the adoption of the union or consolidated school system with specialized teachers and adequate equipment. What the hospital is to the medical profession and what the school building is to the teacher, the health center is to the public health officer. Until the conception of the local health center, many neighborhoods in counties and cities had no concrete object lesson, to fix in their minds the meaning of public health work, and had no personal contact except through a quarantine sign or an abatement notice with the health department.

Furthermore, the recent knowledge of the direct bearing upon health and disease of social medicine relating to the personal habits, emotional make-up, occupational adjustment, housing conditions, nutrition and food habits, and a host of other related influences, has meant a readjustment of our program. The idea of treating the family as a unit in the application of modern preventive sciences, both social and medical, rests upon a firm foundation. The recent knowledge of nutrition, the necessity of proper foods in the prevention of dental decay and dental infection brought into

the picture both dentists and trained nutritionists. The discovery that the X-ray was the most important single instrument in the early diagnosis of tuberculosis and an absolute necessity in childhood tuberculosis added to our armamentarium. The increasing use of the laboratory and the importance of the time factor in the diagnosis of infectious disease both from the standpoint of treatment and epidemiology meant bringing the laboratory closer to the people and to the doctor.

In our newer problems of public health the question of economics has become uppermost in our minds. It was therefore a natural step that there be brought together in the same building the health officer with his newer equipment, the social worker, and the medical practitioner. Such a program reduces overlapping of functions and waste of public funds, and enables us to serve a family with all of the necessary forces to effect a cure, to prevent the spread of disease, and to promote the health and longevity of the people. Furthermore, it seems necessary to take steps to get down in under the causes of indigency, especially medical indigency, and to study the means and measures that may be taken toward prevention.

During the past 20 years, in justification of our program in Los Angeles County, we may state that the County Health Department has returned to the people a dividend of 600 per cent on the money expended. Infant mortality has been reduced from 92.8 per 1,000 births in 1916, to 38 in 1933; the infant mortality among the white races in my territory is now 34. The death rate from diphtheria has been reduced from 16 per 100,000 population to less than 1. Typhoid fever, previously an extremely common disease, now shows a death rate of only 0.38 per 100,000 population. Tuberculosis has been reduced to 75 deaths per 100,000 population annually. Whereas previously

there was frequent interference with business activities, and closure of the schools during each winter was common, now such radical action is no longer necessary.

GOVERNMENTAL TRENDS

We come now to certain specific trends outside health departments and allied circles. Officially, the health department, being an organic part of government, is directly affected by political trends. At the present time approximately 17 per cent of the population is being supported and, to a large extent, provided with its medical needs by government. President Roosevelt has further announced a program of social insurance to be presented at the next Congress. California has taken the lead in appointing a Senate Committee to survey officially the high cost of illness and if in the judgment of this committee there is need for legislation directed toward aiding in the solution of this problem, the committee was instructed to present a Health Service Insurance Act to the coming session of the Legislature.

Senator Edward H. Tickle of this committee, in a public statement,⁷ says:

The Committee is aware of the violent controversies that attended the establishment and administration of this plan in other countries. The whole history of sickness insurance leads one inevitably to conclude that as, if, and when it is adopted, it *will* be adopted in response to public need and interest and over the opposition of special groups with private interests. I think we must agree that the interests of the public are paramount.

The California Medical Association has appointed a director and made available a sum of money to secure facts regarding the problem of health or sickness insurance or other provisions to meet this situation. Michigan has made a notable survey and adopted in principle a plan called Mutual Health Service,⁸ which is a plan to provide through the agency of a non-profit or-

ganization, health services at agreed costs to employed persons and their families whose annual income does not exceed \$1,500. This plan is deserving of encouragement by health officials throughout the United States. It provides for both curative and preventive care, and it is suggested that both the state and local health officers be made members of various committees when it is adopted. Under such a plan the health officer would be made responsible mainly for an educational program, both of the public and the medical profession. Regardless of the ultimate working out of such a plan, the aggressive leadership of the Medical Society of the State of Michigan is worthy of our admiration.

The health officer has been concerned vitally in meeting the continual reduction in budgets made largely in order to build up appropriations for local welfare departments. These departments have likewise encroached on the field of public health in taking over by reason of large appropriations many functions belonging to health departments. There is a strong trend toward consolidation of overlapping health functions in the creation of larger areas. It is proposed in California to consolidate the 58 counties into 14 large regions. *Shall the health department become merely a regulatory organization for law enforcement? or shall it play a major part in these newer programs?* Many health officers believe that the public health department is the logical authority to direct and consolidate the newer advances in meeting the economic problem of the masses in the care of the sick.⁹ Such a program, combining preventive and curative work, surely answers the critics of the European systems of health insurance.

By training, experience, and knowledge of the basic facts, I believe that the public health department should be recognized by the authorities and given

a major function in the new program of socialized medicine for those persons in the under-privileged class. I believe, further, to meet our present situation, that the American Public Health Association should make an effort with the proper authorities at Washington to see that grants of money now being given solely for relief purposes to states and counties be also given to health departments to meet our general curtailment in budgets. Most of the money stricken from health department budgets goes to local welfare organizations. The health needs of the unemployed and the indigent are just as important and in many instances more important than the relief problem. I therefore propose that the Federal Emergency Relief Agency be requested that in any city or county where the budget of the health department has fallen below a minimum of \$1 per capita a grant in aid be given in any instance where sums of money are allocated for relief purposes.

THE PRIVATE CITIZEN

In all of the discussions we hear very little indeed concerning the rights of man himself. The Children's Charter visualized to us those fundamental rights for the mother and child, but the child cannot be segregated from his family or his community. Unfortunately, nothing definite exists in the Constitution of the United States concerning the individual's right to health. Health must be interpreted as a part of the general rights of man. Neither is there anything specific in state constitutions except in so far as they create opportunities for health. Unfortunately, too, there is a strong tendency today to limit the health rights of individuals to those who can qualify as paupers. Demands are being made even to limit public health service to paupers. To further cloud the issue, no two agree as to who is an indigent person. We should protest against certain tendencies of today,

on economic grounds as well as on the principle of human rights, which permit an individual to exhaust his resources and likewise reach an advanced stage of his disease before the government may help him. In such diseases as tuberculosis, cancer, syphilis, and many others, not only is the cost to the government then far greater, but so far as the patient is concerned, much too late.

SUMMARY

1. The problem of rendering an adequate health service in a broad way to our American people is affected by the same difficulties which brought distress to industry—namely, overproduction, mal-distribution and ineffective demand. It is significant that the same amount of money expended today by individuals, to a large extent wastefully, would through a system of health insurance provide an adequate system of medical care. Such a system is particularly needed by those earning \$1,500 annually or less.

2. The situation cannot be materially improved by curtailment of production of regular doctors, since records show that cultism rapidly fills the place of the vanishing general practitioner. Distribution remains untouched, and effective demand must be increased through an enlarged program of health education. Universal basic science laws are needed to control cultism.

3. Health education must include at present both mass and personal instruction. In competition with cultism and quackery, demonstration and individual services are necessary to win many people back to scientific medicine.

4. The services of the health officer are not circumscribed by social status, or limited to the pauper class. While the health officer should encourage all persons able to pay to secure service from the private physician, diagnosis and preventive services in the control of communicable disease must be free to all citizens regardless of social status.

5. The health officer must discharge his duties in the most efficient and economical method possible. So long as such simple functions as immunizations, diagnosis of tuberculosis, and child hygiene instruction can be performed by health departments at one-tenth the cost of such work privately done, the department is obligated to perform the functions itself. Direct methods of solicitation of persons for private practice by public employees

is fraught with grave danger of diminished public support. No other governmental function is performed in such a manner.

6. Consolidation of health functions of individual overlapping health units should be encouraged, creating larger regional areas, and integrating health functions now often the source of much public criticism of waste of money.

7. The health center as an instrument to bring about effective coördination of social, medical, and preventive community activity has proved itself necessary in developing a new technic in disease prevention and health promotion.

8. Basic health department functions as defined by the American Public Health Association must be preserved and financially rehabilitated. Federal funds from the F.E.R.A. or other agencies should be made available through the U. S. Public Health Service to subsidize weakened state and local health departments in stricken, impoverished areas. Subsidies might be based on \$1 per annum for each unemployed person in such areas, with the provision that local government, if possible, bring the total health budget up to the minimum of \$1 per year for total population.

9. President Roosevelt has announced a message on Social Insurance at the next Congress, and the New Deal promises much for the improvement of the public health. A new interest in social justice for the individual is in the air. Since the health department is an organic part of government we must prepare ourselves for possible change in administrative problems.

Not alone for reasons of social justice to the individual but for purely economic reasons, government has a stake in increasing appropriations for disease prevention. Huge sums of money, federal, state and local, are now annually expended in caring for persons who have reached helplessness through terminal conditions of disease, much of which is preventable.

The dictum of Hermann Biggs that public health is a purchasable commodity is as true today as when this statement was first made. Public health work returns huge dividends to our people; its stock has never been watered, nor its values inflated. Health service in its larger phase is a problem basically of economics, the solution of which requires earnest coöperation of both public and private interests.

Let us hope that together we may lift somewhat the burden of sickness and distress, disease and disability from the backs of the working men and women of America.

NOTE: Since September 3, 1934, when the above paper was read, considerable progress has been made. The National Recovery Act has passed, granting among other things federal funds for the U. S. Public Health Service and other governmental departments. In California, the House of Delegates of the California Medical Association in coöperation with the State Department of Public Health and the S.E.R.A. authorized an Economic Survey on the problem of medical care. This survey showed clearly the extent of inadequate medical care in the family group earning less than \$3,000 per year. It showed one-third of the doctors of medicine earning less than \$2,000 in 1933 (net); one-half earning less

than \$3,000 (net); and three-fourths less than \$5,000 (net). Approximately 20 per cent of the persons surveyed were in need of medical care, and only 40 per cent in need were obtaining aid.

As a result of this survey the House of Delegates of the California Medical Association adopted a resolution approving health insurance and recommending that legislation be proposed seeking to establish a health insurance system mandatory as to certain population groups and voluntary as to certain population groups, including the following principles: (1) that the patient shall have absolutely free choice of physician and hospital; (2) that the medical profession shall determine and decide all matters relating to professional standards; (3) that there shall be no provision for cash benefits; (4) that the patient shall receive adequate treatment and his physician shall receive adequate compensation; (5) that these principles shall be maintained with such modifications as may be from time to time recommended and approved by the profession.

The California Senate Ad Interim Committee on Health Insurance with the assistance of a committee representing the California Medical Association prepared and introduced Senate Bill #454 proposing voluntary health insurance for persons above a family income of \$3,000 a year, and a compulsory system of health service insurance on all persons where the family income is less than \$3,000 per year. While the bill is undergoing many modifications it is thought that it has a possible chance for passage at this legislature.

In Japan

JAPANESE villages without medical facilities are to have them provided through the munificence of Mitsubishi, a famous millionaire, who has given 6,000,000 yen (\$2,340,000) for social welfare work. About \$600,000 will go for village medical service. Over 3,500 villages are without doctors and 1,000 are in "urgent need," according to the Japan correspondent of the *Journal of the A.M.A.*

A clinic or office will be built in each village at a cost of about \$600 and by 1936, 1,000 doctors will be appointed to these remote villages. As a rule, there will be no medical fee in case of poor farmers and fishermen, but for well-to-do people there will be a small fee, which is expected to be paid chiefly by the annual relief fund or from special grants made by the emperor yearly.—*N. Y. Journal of Medicine.*

Fluorine Toxicosis

A Public Health Problem*

MARGARET CAMMACK SMITH, PH.D.

Nutrition Chemist, University of Arizona, Tucson, Ariz.

THE widespread occurrence of mottled enamel, a defect of the teeth which is caused by the action of fluorine present in many public and private water supplies, makes fluorine poisoning a public health problem.

We recognize at least 3 types of mottled enamel as may be seen in Plate I, the mild chalky white type, the more severe stained type, and the pitted, corroded type.

It is obvious that mottled teeth are very disfiguring and ugly, for the stain which commonly filters into the porous areas is usually rust colored. In addition, mottled teeth are defective in formation and calcification and are, therefore, structurally weak. The defect is irreparable and permanent. It has been estimated by the Tucson Dental Association that it would cost \$1,000 for dental care of the teeth of the average person with mottled enamel, up to adulthood, at which time the teeth must usually be replaced by false ones.

Fluorine is very common in nature, occurring in many rocks and soils, and ranks 20th in quantity in the earth's crust. It is natural, therefore, that fluorine should find its way into many water supplies, and when it is realized that drinking water containing as little as 1 p.p.m. of fluorine will cause mottled

PLATE I—Typical cases of mottled enamel in human beings who drink water containing fluorine.

enamel, it is not surprising that there are sections in every country in the world and in 24 states of the United States* in which mottled enamel is reported and most of the native born inhabitants are afflicted. It is perhaps most prevalent in the arid states of the Southwest. Our survey¹ of Arizona

made in 1931 has revealed more than 45 scattered communities in which mottled enamel is endemic. The fluorine content of the water supplies in these communities varied from 1 to 6 p.p.m. The only other extensive state survey which has been made is that of Colorado. Boisevain² reports the occurrence of mottled enamel in 25 communities in Colorado. In all probability, mottled enamel is equally as prevalent in other states, especially Texas and New Mexico.

Mottled enamel has been produced experimentally in albino rats, in guinea pigs, and in dogs (see Plates II and III)³ by the feeding of fluorides or the residue of water from a community which contains fluorides. A number of lines of evidence indicate that the fluorine passes into the blood stream and interferes with the calcification of the unerupted teeth of children. It does not act in the mouth upon the enamel of the erupted portion of the teeth. The teeth of children or adults who do not begin drinking water containing fluorine

until after their second sets of the teeth have erupted do not later show mottled enamel.

In humans, the enamel organ disappears as soon as the enamel of the permanent teeth is completely formed and calcified. The enamel does not regenerate itself and behaves, therefore, like dead tissue. For this reason the enamel of the teeth of adults is un-

PLATE III—Effect of fluorine feeding upon the permanent teeth of a dog. Note corrosion and chipping of the enamel.

affected by the drinking of water containing fluorine. It is almost possible to tell at what age a child moves into a community whose water supply contains fluorine, by the teeth which show mottled enamel. If the person has lived from birth in a community in which mottled enamel is endemic, all of the teeth will be mottled. If a child moves into such a community after the age of 12 to 13 years, only the wisdom teeth will be mottled, for they will all have erupted before he drinks the fluorine containing water. Again, a child who begins to drink fluorine containing water at the age of 5 to 6 years will have no mottled enamel on the 6 year molars, central incisors, and probably the laterals, but will have mottled cuspids, bicuspid, and second molars, for these teeth are in the process of formation at this age.

Experiments on rats whose incisor teeth are continually growing also have demonstrated that the feeding of fluorides does not mottle the erupted portion of the incisors, but it is only the new incisor growth which erupts 2 to 3 weeks after the beginning of the feeding of fluorine which shows the characteristic defect.

We have injected sodium fluoride subcutaneously, and again the evidence indicates that the injected fluorine goes to the site of enamel formation and interferes with the calcification of the enamel of the unerupted portion of the incisors. In rats with intermittent injections of fluorine, the results appear in about 3 weeks after the first injection (Plate IV). The lower incisors of the rat completely renew themselves every 30 days. Normal enamel areas alternate with the areas of defective calcification, the extent of which corresponds with the interval between the injections. The mottled appearance of human teeth may well be explained by an intermittent use of fluorine containing water, or a daily variation in the amount of the drinking water consumed.

Although it is true that the enamel of adult teeth is unaffected by fluorine, the dentine of adult teeth which does receive nutrients from the blood stream continually and whose composition is subject to change, may suffer. Histologic examination⁴ suggests that this may be the case. A microphotograph (Plate V) of the incisor of a rat which received 8 injections of sodium fluoride showed 8 stripes in the dentine which was

PLATE IV—Effect of intermittent injections of sodium fluoride. Different effects can be produced by varying the interval between the injections and the amount of fluoride injected.

PLATE V—Microphotographs of incisors of rats receiving injections of sodium fluoride. A. Eight injections given on alternate days resulted in 8 decalcification stripes in the dentine. B and C. Transverse ground sections showing stratification in both the dentine and the enamel of the incisors of a rat which received 4 injections of sodium fluoride given at 48 hour intervals.

tine formed before and after the injections were begun was normal. Plate Vb shows a cross-section of the incisor of a rat which had received 4 injections of sodium fluoride. Stratification in both the enamel and dentine may be observed.

It may perhaps be concluded, therefore, that the dentine portion of the teeth of adults who drink fluorine containing water may be adversely affected, resulting in a general weakening of the tooth structure, although the change will not be externally visible.

The question naturally arises then as to the effect of fluorine upon bone. High fluorine feeding (0.1 per cent NaF in the ration) produced a short, square, and stocky appearance in the skeleton of the rat, with the enlarged, deformed bones and bowing of the legs typical of severe rickets. In addition, the bones of the fluorine fed animals, like the teeth, were chalky and fragile. A measurement of the storage in the body of the bone forming elements, calcium and phosphorus, as determined by measurement of the balance between the intake and the output showed that the young fluorine fed animals retained only slightly more than half as much of these elements as did the normal litter mate rats which served as controls (Table I).⁵ The fluorine increased the loss or elimination of calcium, and bone

TABLE II

CALCIUM AND PHOSPHORUS BALANCE EXPERIMENTS WITH GIRLS

Subject	Age	Retention per Kilo Body Wt.		Per Cent Excretion in Urine	
		Mg. Ca per da.	Mg. P per da.	Calcium	Phosphorus
Mottled enamel	10	5.1	1.7	15.7	62.5
Control	10	3.7	1.0	5.5	55.1
Mottled enamel	13	1.4	3.5	12.6	73.3
Control	13	1.4	5.9	5.7	70.2

development was accordingly retarded. Addition of calcium to the diet, however, prevented this loss to a large extent but at the same time the teeth remain severely mottled.

Similar experiments performed on girls of 10 and 13 years who had mottled teeth, due to the fact that their drinking water contained fluorine, did not show a disturbance in their ability to metabolize either calcium or phosphorus (Table II). No signs of bone defects or other indications of defective mineral metabolism have been observed in children whose teeth are severely mottled. It may be concluded that although the drinking of water containing from 1 to 6 p.p.m. of fluorine will severely impair the teeth, the calcification of the bones is probably not upset to any great degree. The teeth are extremely sensitive to fluorine which seems to exert a more specific effect upon them.

Our work has also shown that the interference of fluorine with the calcification of the teeth cannot be prevented by increasing the calcium content of the diet or by a liberal intake of vitamin D in the form of cod liver oil or viosterol. Supplemental feeding of vitamin D concentrates to rats, dogs, and children over a period of years has in no case prevented the action of fluorine or made its effect upon the teeth less severe.

Mottled enamel is usually found only on the second or permanent set of teeth. We have examined thousands of chil-

dren and noted that the deciduous teeth were free from mottled enamel, whereas all the erupted permanent teeth were mottled. It is believed that the formation of the temporary teeth begins about the 3rd week of fetal life and they are largely calcified at the time of birth. The eruption is usually complete at the age of 2 to 2½ years. In explanation of this almost complete freedom of deciduous teeth from mottled enamel, McKay said "It must be remembered that the temporary teeth are formed largely before birth and are sheltered against outside influences, with a nutritive supply dialyzed through placental osmosis." It is true that thousands of cases have shown that even though mothers drink water containing sufficient fluorine to cause severe mottled enamel (as much as 6 p.p.m.), the deciduous teeth of their children are free from this defect. If the children drink this water from birth however all of their permanent teeth are severely mottled. It would appear that a toxic concentration of fluorine does not find its way through the placental membrane or into the milk supply of the mother.

In support of this, our experiments with rats have shown that even though we feed a high concentration of fluorine (0.05 per cent NaF in the diet) to pregnant females, their offspring have normal teeth at the time of weaning which later become mottled when the young rats have access to the food of the mother animals. Phillips⁶ has

shown that feeding a large amount of a mineral supplement to lactating cows containing enough fluorine to produce a toxic effect upon the cows themselves, did not appreciably increase the fluorine content of their milk. From this evidence it seemed likely that the milk of cows raised in regions in which the water supply contained fluorine could be considered safe from the fluorine standpoint and that pregnant and nursing mothers could drink the fluorine containing water without endangering the temporary teeth of their children.

However, our more recent findings make this conclusion somewhat untenable. A district has been recently visited in which the native born children have mottled enamel of the severest type upon their temporary teeth. This extreme condition was not suggestive of mottled enamel at first glance, for the characteristic chalky whiteness of the enamel could not be observed as the teeth were almost devoid of enamel and ground down almost to the gum line. Analysis of the private water supplies in this section of the state revealed fluorine contents varying from 12 to 18 p.p.m., the highest fluorine concentration yet reported for potable water supplies. It would appear therefore that deciduous teeth are *not* exempt from the toxic action of fluorine and that they will become mottled if the water supply contains an extremely high concentration of fluorine.

Fortunately, the occurrence of mottled enamel is sectional. Colorado Springs is perhaps the largest city where the water supply contains fluorides. There is an agricultural practice which, unless controlled, will make mottled enamel more prevalent and no longer sectional in distribution. I refer to the growing use of fluorine compounds as insecticide sprays against agricultural pests. Fluorine compounds are being more and more extensively used as a substitute for arsenicals whose

toxic action is known and feared. Cryolite, barium silicofluoride and sodium silicofluoride are among the compounds now rather commonly used for spraying apples in the Northwest, and vegetables such as cabbage, cauliflower, broccoli, celery, etc., especially in Florida and California. The fact that these compounds of fluorine are relatively insoluble has raised the question as to their toxicity. Our study⁷ on rats, of the comparative toxicity of fluorine compounds has shown that from the standpoint of the initial damaging effect upon the teeth all are equally poisonous. One mg. of fluorine per kilo of body weight per day, or a concentration of 14 p.p.m. of fluorine in the ration of rats, regardless of the source of the fluorine, will prevent the normal development of the incisor teeth.

Fluorine is even more toxic to the teeth of human beings than to rat incisors which grow at a more rapid rate. A concentration of only 1 p.p.m. in water supply will produce mottled enamel in humans. If we assume an average water intake of from 4 to 8 glasses a day, the average fluorine intake per day from this source will be from 1 to 2 mg. per person.

Analyses of the fluorine residues on food material have been made by the U. S. Department of Agriculture 3 months after the foods were sprayed with various commercial fluorine sprays. Apples sprayed with barium silicofluoride showed an average fluorine content of 5.6 p.p.m. before washing. One of these large apples would therefore provide as much fluorine as 4 glasses of water containing 1 p.p.m. of fluorine. The fluorine residue on cabbage varied from 1.6 to 11 p.p.m., on celery from 9.9 to 28, on cauliflower, from 1 to 3.

Experiments upon the removal of spray residue by washing have been made by Smith and his coworkers of the U. S. Department of Agriculture. They report that fluorine residue removal

amounts to only 85 to 90 per cent by the best washing process available so that "it was impossible satisfactorily to clean fruit originally carrying 0.1 gr. or more of fluorine per lb." They also state that the fluorine residue on fruits sprayed with cryolite or barium silicofluoride plus fish oil was practically impossible to remove to meet the fluorine tolerance set by the U. S. Department of Agriculture even when the most efficient methods were used. It seems logical to suppose also that it would be even more difficult to remove fluorine from the leafy vegetables than from apples.

With the human tolerance level for fluorine so low, it seems a dangerous

practice to use the compounds of fluorine for spraying purposes. The ugliness of mottled teeth alone causes untold misery to the afflicted persons.

Cure for Stubborn Wounds

FROM a clue provided by an insect, entomologists of the U. S. Department of Agriculture have discovered a new way to heal stubborn wounds quickly, painlessly, and cheaply. The new treatment is the application of a solution of allantoin, a bland, odorless, harmless, and easily obtained product found in both insects and plants.

The insect that gave the clue to this discovery is one of the flies—in the maggot stage—that gained fame as a medical aid on World War battlefields, where an Army doctor found that wounds infested with maggots healed better and faster than wounds without

them. Since then surgeons all over the world have used maggots in treating deep infections difficult to cure by ordinary surgery.

Dr. William Robinson, of the Bureau of Entomology and Plant Quarantine, now finds that allantoin, which is given off by the maggots as they work their way through a wound, is responsible for part of this power. Dr. C. J. Macalister, who used it successfully 23 years ago for ulcers, reported that European peasants had long applied the roots of comfrey, which contain allantoin, to sores.—Press Release, U. S. Dept. of Agriculture, Apr. 23, 1935.

American Standards for Exhaust Systems

CYRIL AINSWORTH

Assistant Secretary, American Standards Association, New York, N. Y.

BECAUSE the Safety Code for Exhaust Systems is now in the process of active development, and in view of the participation of the American Public Health Association in this project through its Industrial Hygiene Section, it was felt desirable by your officers that the plans for carrying on this activity be presented to you for your consideration.

Before going further into this specific question it might be well to present a brief picture of the American Standards Association. Some of you have participated in the development of standards under A.S.A. procedure and are therefore somewhat familiar with its methods of work. With others this is not the case.

The A.S.A. was organized in 1918 by 5 of the major technical societies (mechanical, electrical, civil, and mining engineers and the Society for Testing Materials) for the purpose of properly coördinating the engineering and industrial standardization work which they had been carrying on individually. The organization was then known as the American Engineering Standards Committee. The change to an Association was made in 1928.

The objects of the organization are:

To serve as a clearing house for standardization work in the United States

To further the standardization movement as a means of advancing national economy

To serve as a bureau of information on standardization matters

To act as the authoritative American channel in international coöperation in standardization work.

A large variety of standards is handled including:

1. Nomenclature
Definitions of technical terms used in specifications and contracts and in other technical work
Abbreviations
Symbols for quantities used in equations and formulae
Graphical symbols
2. Uniformity in dimensions necessary to secure fits; and to provide for the interchangeability of parts and supplies, and the interworking of apparatus
3. Quality specifications for materials and equipment, both for producer goods and for consumer goods
4. Methods of test
5. Ratings of machinery and apparatus which establish test limits under specified conditions as a basis of purchase specifications, or which establish requirements as to performance, durability, safety, etc., under operation
6. Provisions for safety
7. Rules for the operation of apparatus and machinery in industrial establishments
8. Concentration upon the optimum number of types, sizes, and grades of manufactured products

The work is carried out by simple but systematic methods of coöperation, through which all groups interested in any particular project participate: (1) in deciding whether the work shall be undertaken at all; (2) in formulating the standard; and (3) in its ultimate approval as an "American Standard." The arrangement is flexible, and alternative methods have been developed, as the result of experience, all based upon

the same principle, *viz.*, the assent, affirmatively expressed, of the groups having a substantial concern with the scope and provisions of the standard.

The usual method is that of a joint technical committee, made up of representatives of the various interested groups. These joint committees form effective cross-sections of the interested groups, and are called sectional committees. This is the method being followed in the development of the safety code for exhaust systems. In large projects such as this the detailed work is generally drafted by sub-committees.

To date, 266 standards have been approved and 173 others are under way. In this, more than 600 national organizations are officially participating. Approximately 3,000 experts are serving on the various committees.

A very important group of the standards approved by the A.S.A. is that group comprising the 40-odd safety codes. This phase of A.S.A. work was initiated in 1919 following two conferences held in Washington, D. C., under the auspices of the U. S. Department of Labor and the National Bureau of Standards, called to discuss ways and means of obtaining relief from the situation caused by the multitudinous number of conflicting rules, regulations, and safe practice recommendations, which had been developed and promulgated by regulatory bodies, insurance groups, trade associations, and individual companies. As a result of the discussions the A.S.A. was requested to extend its scope of activities to include the development of safety codes on a national basis.

The American Standards Association accepted this mandate and changed its form of organization to include a safety group composed of the National Safety Council, both stock and mutual casualty insurance companies, the U. S. Department of Labor and the National Bureau of Standards. A National ad-

visory committee now known as the Safety Code Correlating Committee was organized to advise the A.S.A. in regard to the nature of the projects that should be undertaken, the appointment of technical committees, the scope of the work of individual projects, and to determine the degree of consensus that has been arrived at on the acceptability of codes submitted for approval as "American Standards." In addition to the organizations just mentioned, several industrial groups—fire protection organizations, the International Association of Industrial Accident Boards and Commissions, and the Association of Governmental Labor Officials—are represented on this national advisory committee.

The program developed by this committee has grown in the number of codes completed and under way, and in the extent of the use of A.S.A. Safety Codes by regulatory bodies, insurance groups, individual trade organizations and companies. Many departments of labor and industrial accident commissions have either adopted many of the codes verbatim or used them as the basis of state regulations. The National Compensation Rating Schedule of the insurance companies has been brought into harmony with A.S.A. codes. In states where the schedule is no longer effective, American Standard Safety Codes are used as the basis of insurance recommendations for the removal of accident hazards in industrial establishments.

A number of important safety codes are under development at the present time. Some of these were initiated as part of the original program outlined by the Safety Code Correlating Committee.

The code for exhaust systems is such a project, and although a number of years have elapsed without much progress being made, it is gratifying to report that the committee is now quite active.

When the code for exhaust systems was initiated some years ago it was intended that its scope would cover the construction and operation of such systems from an engineering point of view. The delay in developing a code around this scope came chiefly through the conflicts of opinion existing in the group comprising manufacturers of exhaust equipment. Some believed that trade secrets were involved. Others differed as to the engineering principles involved. All of these differences resulted in years of delay. Finally the organization which was then sponsor for the project, the American Society of Heating and Ventilating Engineers, asked to be relieved of its duties as administrative leader for the work in order to be able to devote all its attention to the ventilation code. The request was granted and the International Association of Industrial Accident Boards and Commissions took over the administrative responsibilities for the work.

The new sponsor immediately proceeded to reorganize the sectional committee. New organizations were added, and representation of other organizations were changed. Since this reorganization has taken place two meetings of the committee have been held and a new scope and a plan of operation have been adopted.

The sectional committee has decided to approach the very difficult task with which it is faced by developing, step by step, a set of separate standard specifications for exhaust hood designs and air velocities for each distinct process or industry. Thus each group of specifications will constitute a separate standard applicable only to the specified process or industry. Initial projects upon which sub-committees are about to be appointed are as follows:

1. Abrasive Cleaning
2. Chromium Plating
3. Granite Cutting
4. Rock Drilling
5. Spray Coating

While it is contemplated that additional exhaust specifications will be developed for additional processes as opportunity offers, the above group was chosen because there appear to be already available sufficient data from field studies and laboratory research upon which reasonable and adequate standards can be based.

During the past several years there has developed in many industries throughout the country a very exceptional and severe claim situation based on the alleged exposure of industrial workers to a considerable variety of materials that contaminate the workroom air—the claims being based on so-called “occupational diseases” resulting from the inhalation of air containing allegedly injurious substances in dangerous concentrations. While the accurate evaluation of these occupational disease claims is a medical one beyond the scope of A.S.A. undertakings, the problem of minimizing the exposures in question is largely an engineering problem of exhaust equipment applied to the process that causes contamination of the workroom air, a problem quite amenable to standardization. No uniformity of practice throughout industry has developed as yet to meet the situation.

Of considerable importance in this connection is the wide variation in existing State Labor Department Regulations that have been promulgated to correct the hazards here in question. In many instances, these regulations are too general in phraseology to prove of assistance to industry in applying specific corrective measures. In other instances the standards of performance are set impracticably and unnecessarily high. In general, it is fair to say that these local regulations have not been worked out with sufficient technical skill to prove of practical value to plant managements in their efforts to solve their occupational disease problems. This is quite understandable as very few

if any of the regulatory bodies have had sufficient funds, particularly during the past few years, to enable them to carry on the research and field work that is so essential in securing adequate information. One might also raise the question as to whether or not the best results can be obtained if a considerable number of independent research projects on the same subject are undertaken. It would seem much better if such activities could be correlated through one central clearing house and in connection with a well thought out and well coördinated plan of standards development.

In addition, and quite unfortunately, the mere technicalities of state regulations are at times being utilized in law suits to establish the legal status of negligence more or less regardless of any medical proof that injury has actually been received by the claimant in the course of his employment.

It is the hope of the Exhaust Code Sectional Committee that national standards for exhaust of numerous industrial processes can be developed with such weight of technical authority back of them that these "American Standards" will either be used verbatim by state regulatory bodies, or that the technical principles established in the

standards will be used as the basis of state regulations. The committee hopes to appoint an advisory committee of toxicological, pathological, and engineering experts to assist in the determination of threshold limits for the toxic dusts, gases, and fumes, that are to be removed through the use of exhaust systems. This, it is hoped, will tend to coördinate the existing points of view of experts, and also give the standards the authoritativeness which will automatically obtain the acceptance which the committee anticipates.

Already the financial losses incurred by industries throughout the country from occupational disease claims have mounted into millions of dollars, and there appears to be an increasing demand from all persons interested that adequate but practically reasonable standards be developed for these hazards, especially along the lines of exhaust equipment which is the logical solution of the great majority of industrial hazards of this type. The Exhaust Code Committee has an extensive problem before it that involves a considerable volume of detail and it welcomes the full coöperation and participation of the American Public Health Association in this work.

The Future of the Program for Tuberculosis Control*

KENDALL EMERSON, M.D., F.A.P.H.A. (*Life Member*)

Director, National Tuberculosis Association, New York, N. Y.

THE decline of the tuberculosis death rate in this country to one-third its 1900 level is not an accident. On the contrary it is an outstanding example of man's capacity in certain measure to carve out his own terrestrial destiny. To no one cause can be attributed even major credit for this triumph. It has not resulted from the discovery of any specific cure. The achievement was possible only by combining all the forces of medicine, public health, social and industrial welfare in a common effort to control this greatest menace to race survival.

Among the factors involved in the concerted attack on this disease the National Tuberculosis Association has at least played a persistent rôle. In the past ardor of youth it may have claimed more than its share of accomplishment. In its maturity it is operating in closer harmony with its official and unofficial colleagues. In the future it seeks an opportunity to supplement even more effectively the work of those coöperating health and social welfare agencies through whose joint activities the organized attack on tuberculosis looks forward to ultimate victory.

Already there is a fair measure of agreement as to the trends that a future program must take. This can be shown

without too great detail by observing certain historical characteristics revealed by an examination of the statistical record of the declining mortality rate.

In 1932 Dr. Hofbauer published a report¹ discussing a chart (Figure I) which he had compiled showing the death rate from tuberculosis in differing cultural groups in the city of Hamburg during a period of 30 years. At the beginning of this period it could be shown that the industrial and poorer classes exhibited a death rate several times that prevailing among the more intelligent and more fortunate economic groups of the community. This fact is consonant with our general knowledge of the epidemiology of tuberculosis.

The significant interest in Dr. Hofbauer's investigation lies in the extension of the two mortality graphs. He found that as organized efforts to improve public health proceeded the gap between the curves steadily lessened. At present the lines have drawn practically together and the contrast between classes tends to disappear. His conclusion is that the rough work of tuberculosis control is nearing accomplishment. The difference in death rate due to social differences, industrial causes and underprivilege will not be so evident in the future. We cannot hope for further marked lowering of mortality through the alleviation of environmental causes alone. From a situation where almost any improvement in sanitation and personal hygiene would re-

* Read before the Health Officers Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 6, 1934.

FIGURE I—Tuberculosis death rates per 100,000 for income groups of 1,200-2,000 and 3,500-5,000 marks. Hamburg 1902-1914; Baden 1924-1928. Allowances are made for changes in value of the mark and these income groups include only taxpayers without dependents

duce the tuberculosis mortality concurrently we have reached a point where far more intensive methods of control must be applied to secure comparable progress in the fight.

In other words we have arrived at a situation where tuberculosis control ceases to be a business enterprise with much that is mechanical in its program, and becomes an art in the sense that we use the term when describing the practice of medicine. Shotgun procedures, effective in the past, are not destined to bring similar results in the future. Already there is some evidence here and there that the rate of decline is straightening out rather than pursuing its reassuring downward career.

Stimulated by this somewhat striking observation in Hamburg, I asked my statistical department for any evidence which our own records might disclose. A means lay fortunately at hand. The Metropolitan Life Insurance Company maintains its own mortality rates for tuberculosis. They represent the fatal occurrence of the disease among a very large group of industrial workers including varying social levels but excluding

in some measure at least those members of society to whom we refer as belonging to the privileged classes.

Against the Metropolitan graph we have placed the graph for the whole population (Figure II) and we see at once a striking resemblance to the somewhat related study made in Hamburg. Certainly it would appear to be a reasonable inference that in our own country the rough work of tuberculosis control had accomplished its more picturesque achievements and that now we may well assume that we are settling down from a period of rapid advance against a more obvious enemy to a perhaps longer period of trench warfare where our objectives are not nearly so visible and our hope of rapid progress is much less secure.

Realizing the crudity and incompleteness of these two studies I should not have ventured to present them save as corroboratory evidence in justifying two changes in program which mark the future plans for tuberculosis control. The first of these is the recognition for some time past that while general improvement in standards of living is

still to be fostered as vigorously as before, special attention must be focused on selected industrial groups and on certain racial subdivisions of our people where a lag is revealed by our more intensive statistical research. Already this change in our aim has begun, already we are beginning to use the rifle in place of the old shotgun and to shoot at predetermined targets, instead of blindly at the whole flight of birds as we have done with admitted success in the past.

But a few years ago there was in operation an extensive campaign to eliminate dust from industry on the ground that all dust was irritating to the lungs and therefore predisposed to tuberculosis. That was wise for the moment, since minimum quantities of dust make for maximum comfort to employees and perhaps lead to increased

efficiency. But it was a shotgun procedure for it was soon learned that many dusts appeared to have little if any effect on the actual development of subsequent disease. Then it was that the rifle was brought into use instead, the sights adjusted and the true targets, silicosis and asbestosis, clearly recognized. A late report from Vermont shows that despite our knowledge of this fact and our efforts to control epidemics among granite cutters the rate of incidence has shown steady progress right up to the present time. No better illustration of the need for selecting our targets could be adduced.

Another step for the immediate future is the adaptation of general procedures to the special requirements of tuberculosis control among the several racial groups, Negroes, Indians, Mexicans, which compose a measurable fraction of

FIGURE II—Tuberculosis death rates per 100,000 for Metropolitan industrial policy holders and the general population in the United States Registration Area, 1911–1932

our population. Hitherto it has been found that control methods applicable to the people of the country as a whole yield disappointing results among certain of the subdivisions of population. Why is this? The N.T.A. is attempting to aid in answering the question through the activities of a Committee on Tuberculosis among the Negroes which operates under a grant from the Julius Rosenwald Fund. We feel a deep interest in the effort on the part of the new Indian Commissioner to attack the similar problem presented by the 600,000 wards of the federal government resident on the Indian Reservations.

In addition to the more accurate direction of the tuberculosis control program along industrial and racial lines, there are certain high spots in the mortality graph corresponding to different age groups in the two sexes, and also unfavorable variations in the case of certain professions, among which are those of the physician, the trained nurse, and assistants and technicians in sanatoria and general hospitals. Certain alarming reports regarding the danger to such professional groups have been contradicted, but the actual facts are still too doubtful to justify a feeling of security, and intensive study of the existing situation is first needed, after which consistent measures must be devised to install every practical means of prevention.

The second inference which may be drawn with reason from the observed facts of epidemiology in these two charts is that there may be biological factors of unrecognized significance in their possible influence on our efforts to eliminate the disease. The school of thought which suspects fundamental differences in the human soil upon which the disease may chance to be implanted has a potent argument in the well known contrast in susceptibility to tuberculosis between different species of animals, such, for example, as the dog on the resistant,

and the guinea pig on the highly sensitive end of the scale. The slight but recognized advantage which the Jewish race holds over the general rate may be another evidence of this principle or, as some believe, may be due to social and dietary variations. The notably profound susceptibility of the Negroes and the well known depredations of the disease when introduced into the virgin soil of primitive races also present problems for study and solution upon which must be based certain phases of any wise program for the future.

The story of communicable disease control is inextricably entwined with the advance in our knowledge of the specific bacteria. The tubercle bacillus is among the bacteriologists' oldest acquaintances, yet to the present it remains one of a small group of acid-fast bacteria which refuse to render up certain indispensable information regarding their biological peculiarities. For nearly a decade the N.T.A. has prosecuted intensive research into the behavior and chemical composition of the tubercle bacillus. No ultimate goal is set though the hope of guidance toward the discovery of a specific cure is of course a basic motive underlying this work. Up to the present much carefully recorded pioneer work in chemical and physical analysis of the bacilli has been accomplished, work which has been costly both financially and in human effort, but which will scarcely require repetition, and which adds an ever broadening foundation to build upon in carrying forward future experimentation. The association's program contemplates not only maintaining the studies now in process but seizing eagerly any promising new leads which may present themselves and call for an expansion of the present research policy.

In the field of treatment the expanding employment of approved surgical procedures has made rapid progress.

This development has an important bearing on the epidemiological control of tuberculosis because one of its gratifying results is to render the patient's sputum free from infecting bacteria at a much earlier period, thereby reducing his social menace as a carrier of the disease. We thus have another resource to supplement the policy of segregation upon which much of the present accomplishment depends.

Finally, the future program of tuberculosis control must take solicitous heed of the needs of the arrested case. Ten years ago I requested some statistics from one of our long established state sanatoria regarding its discharged cases and was shocked to receive a reply to the effect that due to the difficulties involved no follow-up records were kept after the return of a patient to his physician or to a local health authority. The difficulties referred to included serious lack of coöperation on the part of the patient himself who did not wish his history of infection to become a social or industrial handicap to his future. A decade of education and training of patients has notably altered this mental attitude and impressed upon them the necessity for supervised read-

justment to normal life if they are to avoid recrudescence of the disease. The rehabilitation of the arrested case is recognized, not only as a part of essential treatment for the benefit of the patient, but as a specific public health function in order to reduce the danger to a community of reactivation with its renewal of infectivity.

Evidence is lacking of revolutionary changes in the future program of tuberculosis control. Sanitation, avoidance of overcrowding, industrial hygiene, and good standards of living are its basic features. Early diagnosis with tuberculin testing and X-ray must continue. Clinics and sanatoria with the preventorium type of care for contact cases must be provided. The follow-up and after-care of arrested cases must be intensified. It is only by the refinement of these measures in the light of accumulating knowledge that we may carry on a gradually successful warfare until that happy moment when there shall be raised up a man of genius to present us with a specific means of curing or preventing tuberculosis.

Recommended Procedures for Diphtheria Immunization

THE Sub-Committee on Evaluation of Administrative Practices of the Committee on Administrative Practice of the American Public Health Association on the basis of studies made at its request by William H. Park, M.D.* offers the following as representing the best contemporary practice in immunization against diphtheria:

Passive Immunization—Limited in application to persons known to be, or presumed to be susceptible to diphtheria, who are exposed to direct contact with a case of this disease, or who remain in the family or household where there is a case of diphtheria in the communicable stage of the disease, under such conditions of unavoidable personal contact as would be likely to lead to infection. Included in this category are Schick-positive children in institutions where one or more cases, or carriers of the virulent form of diphtheria bacillus, have been discovered among the inmates of the institution.

A single intramuscular injection of diphtheria antitoxin of 500 to 1,500 units according to the size of the person (500 for a child up to 5 years of age; 1,000 for a child of 10; 1,500 for an adult) will protect for not more than 3 weeks or less than 10 days. If for a good reason protection beyond the 3 weeks by passive immunity is subsequently found to be necessary, repetition of the same dose will protect for not more than an additional 10 days.

Active Immunization—All healthy infants at 6 to 12 months of age should receive a single subcutaneous dose of 1 c.c. of an alum precipitated toxoid preparation, authorized by the National Institute of Health. This procedure can be relied upon to produce a Schick-negative condition within 2 months, in 95 per cent of such children. Small lumps may be palpable in the tissue at the site of the inoculation for several weeks while the relatively insoluble precipitated toxoid is in process of absorption. The maximum percentage of Schick-negative reactors will be found by 3 months from the date of inoculation. No appreciable annoyance to infants or to children up to 6 years of age results from the use of alum-precipitated toxin in the above described manner. If used in older children, or in adults a considerable local reaction may develop in 5 per cent of persons, and occasionally also a constitutional reaction. Local or constitutional reactions rarely last more than 24 hours. The local reactions may be alleviated by dressings wet with saturated aqueous solution of boric acid.

In persons 6 years of age or over a small dose (0.1 c.c.) of the alum precipitated toxin should be given, and if this causes no annoying reaction within 24 hours one dose of 1 c.c. may be given 1 or preferably 2 weeks later.

If the soluble toxoid preparation is used instead of the alum precipitated toxoid the infant at 6 months of age should receive 1 c.c. subcutaneously or intramuscularly in each of two doses, with an interval of 1 or 2 weeks be-

* Part of the cost of these studies was met out of grants from the Commonwealth Fund for evaluation of public health procedures.

tween them. In 90 per cent of children from 6 months to 6 years of age a negative Schick reaction will develop in previously positive Schick reactors within 3 weeks of the date of the inoculation.

In older children and in adults an initial dose of 1 c.c. is followed, if there is no severe reaction, by a second dose of 1 c.c. after 1 week interval.

If toxin-antitoxin is used in a fresh preparation of suitable toxicity, as many as 80 per cent of Schick-positive children (6 months to 6 years of age) will develop a Schick-negative reaction in the course of 3 months after the completion of a series of three subcutaneous or intramuscular inoculations of 1 c.c. each given at intervals of at least 1 week, and preferably of 2 weeks, between first and second, and second and third doses. In older children the same preparation, doses, and intervals will produce similar results, but the maximum percentage of Schick-negative results may not be reached before 6 months from the completion of the series of three inoculations.

The toxin-antitoxin mixture less often causes reactions in children over 6 months of age and in adults than do the soluble and alum precipitated toxoid preparations, and for this reason the familiar and original toxin-antitoxin is the preparation of preference for persons of school age or older requiring active immunization against diphtheria. Unless the toxin-antitoxin is of the proper degree of toxicity, not more than 50 to 70 per cent of school children or adults are likely to show a change from positive to negative Schick reaction within 3 months of the completion of the series of three inoculations as above described.

Persons who continue to show a positive Schick reaction after one such series of three toxin-antitoxin doses may develop a negative Schick reaction after a second series.

Only in the case of adults exposed to

particular hazard of infection with diphtheria, such as attendants, nurses, and physicians serving in children's and particularly communicable disease hospitals, is it important to carry out a second series of such inoculations in those showing a positive Schick reaction after the first series.

Schick testing—Except for epidemiological purposes and to determine the immunizing effectiveness of a preparation not previously used, there is no particular value in routine Schick testing infants or children between 6 months and 6 years of age, either before or after the use of the single dose of alum precipitated toxoid. In only such children of 6 years of age or over, and adults as have been proved to be susceptible to diphtheria by development of a positive Schick reaction, should active immunization be undertaken, and in these a Schick test should regularly be made 6 months after the completion of the inoculation, whatever the preparation which has been used, to determine whether they have by that time become immune.

The advised choice of age of person, preparation, and dose to give best results for the person and the community, at least individual inconvenience and cost is as follows:

A. Infants at 6 months: Alum-precipitated-toxoid. One dose of 1 c.c., without prior or subsequent Schick testing. Minimum of reactions and maximum per cent of active immunization produced.

B. Children from 6 months to 6 years of age: Same procedure as in A. Reactions slightly increasing with age but unimportant.

C. Children 6 years of age and over, and adults, known to be susceptible to diphtheria: Fresh and adequately toxic toxin-antitoxin mixture in three 1 c.c. doses at intervals of 2 weeks, followed by a Schick test, at the end of 6 months to determine presence or absence of

immunity, with a second series of inoculations for those still showing a positive Schick reaction whose occupation exposes them to a particular hazard of infection.

Only by using toxoid preparations, of whatever variety, with high antigenic potency, at least as high as now required by the National Institute of Health, can the highest percentages of actively immune persons be artificially

developed by use of the single dose of alum-precipitated-toxoid.

Obstetrical Mortality in the United States and Abroad

IN recent years many obstetrical papers have discussed the high puerperal mortality rate of the United States. Much has also been written of the unfairness of comparing the maternal mortality of this country with that of others.

It was concluded by Tandy that the methods of assignment in use in Australia, Netherlands, New Zealand, and Scotland are similar to those of the United States, and the official maternal mortality rates are directly comparable within a small margin of error. Under the method of Denmark a larger number of deaths would be assigned to the puerperal state and the rate for the United States would be significantly higher than now. Under the methods of the other countries included in the study, a smaller number of deaths would be assigned to the puerperal state and the rates for the United States would consequently be lower.

Differences in methods of assignment were insufficient to explain the high maternal mortality rate of the United States as compared with foreign countries. The official figure of the United States, which in the last few years has exceeded that of every country except Scotland, remains high no matter what method of assignment is used.

Even if the method of the country assigning the smallest proportion of deaths to the puerperal state were in use in the United States, the United States figure would still exceed that of all the countries except Australia, Canada, Chile and Scotland. Rates for the United States estimated in accordance with the assignment procedure of the respective countries are in every instance except Scotland in excess of, and are in five instances more than double, the official rates of the countries themselves.—*South. M. J.*, 28, 4:388 (Apr.), 1935.

Selling Health Department Members First on Health Education*

HUNTINGTON WILLIAMS, M.D., DR.P.H.

Commissioner of Health, Baltimore, Md.

THOSE who selected the subject that I have been asked to discuss must surely have had in mind a fairly obvious fact and one which is not given the attention it deserves from health department executives. This fact is that the health education efforts of health departments are usually directed toward the general public as an audience without making use of the entire health department staff, including not only the medical and nursing members but also every stenographer, inspector, and routine worker as potential public health missionaries. I imagine the motive back of this meeting amounts to a challenge which many health departments, including the two with which I have been associated, are not in a satisfactory position to accept.

To be a little more specific, the question seems to be: First, just how interested are the rank and file of employees in a health department in the more vital field programs, such as diphtheria prevention, or the protection of 1 year old babies from exposure to measles during a brisk outbreak? Second, if it is considered desirable, how can a health department best organize and stimulate an interest throughout its entire staff which would result in their presenting to their

friends and acquaintances, while not on duty in the office, the content of the health education program the department is most anxious to spread abroad at any given time?

It occurs to me that some of you may be interested in certain extracts from replies which were received during the summer from a number of health officers to whom I presented the problem for comment. From one city came the following:

In reply to your letter of June 12, I wish to state that we agree with you that only too often do the routine workers in the various bureaus become lukewarm in regard to the program which the department, as a whole, is anxious to develop.

We are trying to overcome this . . . by meetings with brief talks to the workers, giving them the necessary instructions and, at the same time, trying to build up for them a background of motives or reasons for the various regulations and rules, thus getting them interested in carrying forward the work which we desire done.

Another city health officer wrote:

After looking over our various printed instructions to employees, I have reached the conclusion that we really have not anything to offer on the education of the Health Department personnel.

Nearly all of our work is done through conferences. The department heads meet at least once a month with the Commissioner of Health to discuss their problems. The various department heads educate their employees through personal contact and group meetings. The various department heads also give a course of lectures to the public health nurses. The Commissioner and Deputy Commissioner

* Read at a Joint Session of the Health Officers and Public Health Education Sections of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 5, 1934.

of Health give occasional talks to the large groups of employees.

One of the most interesting letters, from a smaller city, included this statement:

During the 10 years that I was Health Officer in . . . , one of the most effective methods for keeping the personnel of the Health Department stimulated, informed and interested in public health work was through our weekly and bi-weekly staff conferences.

The entire personnel of about 70 were present at these Saturday morning meetings. The programs included outside speakers on a wide variety of health topics, and also speakers from within the department informing the rest of the group of their specialty.

On some occasions these meetings went as far as a debate as to the relative value of the type of work that they were doing. The Health Officer, himself, gave a good many of these talks which covered all kinds of health topics from book and magazine reviews, outstanding epidemics in the country, to frank presentation of difficult situations within the department.

Dr. Geiger, whose public health work in San Francisco is a constant inspiration to his friends in the eastern part of the country, called attention, in connection with our problem, to the genuine need for an *esprit de corps* among all the employees in a health department. My predecessor, Dr. C. Hampson Jones, who for so many years was responsible for the public health of Baltimore, was singularly fortunate in his constant efforts to develop what he referred to as "the public health spirit" among nearly all the 535 workers on his staff. Dr. Geiger has pointed out that a health department should have a full-time director for the Bureau of Education who should organize regular classes for employees as well as assume responsibility in the field of health education for the public. This would include planned graded classes as well as special lectures on occasions. Just how far behind many of us are in what we would like to see in the staffing of a public health education bureau in a

health department, I may best indicate, perhaps, by referring to the one full-time public health nurse who with the assistance of a stenographer acts as health education director for us in a city of over 800,000 population. Of course, the answer is that other bureau directors and their assistants coöperate and are responsible for a very large share of our public health education work. Dr. Geiger points the way, as he sees it, as follows:

The full organization of a bureau of education is probably out of reach of most health departments at the present time but the (1) careful introduction of the new employee to the work, (2) a simple department manual kept up to date, (3) occasional or regular bulletins issued to each member of the department, and (4) arrangement for lectures, especially for the non-professional members, all appear not too difficult for realization.

From the Director of the Division of Public Health Education in a large state health department there was received the following:

I certainly believe that public health education, like charity, should begin at home.

I know for a fact that the rank and file in the department seldom read *Health News*, and are interested only in their particular jobs. Ask them anything outside of that and the answer is "I don't know." I do not think that this applies to the professional staff.

Some of the health habits of the rank and file, from personal observations, are what might perhaps be expected of the personnel of a 5 and 10 cent store.

Some years ago in the Capitol, I attempted to start a series of health lectures in the department for the clerks and stenographers, etc. I did succeed in holding a few meetings on social hygiene, but the plan then fell through, partly because of the opposition of directors to giving the employees the necessary time.

The Health Commissioner from another large city has written me:

I feel as you do that it is very important to have some one detailed to the Health Department who gives his entire time to health educational methods. Only in this way can we get over the problems that are continually confronting us. . . .

A broad program of public health education has not been properly organized in . . . up to this time.

Dr. Boucher, Director of Health of the Health Department in Montreal, has written that in his department the employees are gathered together in groups in the different divisions, and under supervisors each week are given information and instructions on health department work in a manner which allows of questions and answers and discussion. In addition more formal lectures are presented and Dr. Boucher feels that these procedures have given splendid results.

From Detroit Dr. Vaughan has written as follows:

It not infrequently happens, I am sure, in many of our large city health departments that we, as Health Officers, fail to carry along in our various projects the rank and file of our own employees. Here in Detroit we have not done as well as we should. Our sanitary inspectors as well as our milk and food inspectors have their regular bureau meetings at which they are thoroughly instructed with respect to their own activities, but we have been somewhat negligent in carrying to them the more complete program of the Department of Health, that is, those activities with which they do not have daily contact.

With our nursing personnel the contrary is true . . . We are looking forward to the time when all of our nurses will not only be graduate nurses but also have a certificate in public health nursing . . .

The courses at the University are closely tied up with the Health Department and the teachers are, to some extent at least, members of our staff . . .

For the past 15 years we have had executive staff meetings in my office . . . All the new procedures are outlined at these staff meetings . . . Each responsible sub-chief in turn must carry these programs to his respective bureaus and divisions.

Briefly, to answer your question I would say that the 3 important tools to be employed are: first, regular methodical meetings of the executive staff; second, regular meetings of the employees in their respective divisions; and third, a tie-up with an institution of learning so as to give the employees, especially the nurses, some academic standing for their work.

Like Dr. Vaughan, we have regular staff conferences of the bureau directors in the Baltimore Health Department which have certainly been valuable in integrating the interests of the different health services. During the past 3 years we have been in a state of fairly complete reorganization resulting, in part, from a 33 per cent budget reduction. One of the most profitable projects in our staff education was the assigning of Professor Hiscock's book *Community Health Organization* to each bureau director for a written review of the chapter dealing with his special activity. These reviews included a comparison of the Baltimore program with the recommendations. This staff study, which is being followed by a similar review of the New York State Health Commission Report of 1932, has turned out in many ways to have been more valuable than had been anticipated.

With the establishment of the Eastern Health District in Baltimore as an administrative unit serving slightly less than 10 per cent of the city population, and made possible through the coöperation of the Johns Hopkins School of Hygiene and Public Health and a number of volunteer health agencies with the City Health Department, there has been afforded an opportunity for field education of our public health nursing staff and some of our medical officers. Dr. Harry S. Mustard, who is Health Officer for the Eastern Health District, has been of the very greatest assistance in the development of an entire course of instruction for our 118 public health nurses prior to the generalization of 2 nursing units; a maternity and child hygiene group of about 25 nurses, which has this summer been merged with the other group of 93 public health nurses, who have been carrying district assignments including school, communicable disease, and tuberculosis work. The other large body of employees who, for a number of years, have been receiving

fairly formal instruction, have been the inspectorial group, including the dairy farm and pasteurization plant inspectors, the sanitary and plumbing inspectors and, more recently, a newly established classification of industrial hygiene inspectors. The Bureau of Laboratories has assisted in all these educational projects.

Perhaps the only other educational effort which has been developed is the annual health examination of all of the 411 employees now on our staff who have volunteered to accept these personal health surveys, rendered without cost by a group of department physicians. Quite naturally certain members of the staff have preferred to have the examinations done by their family physicians.

In questioning a group of our stenographic force, I found that one had been responsible for the toxoid inoculation of her sister's child after there had been a considerable delay because the family physician apparently did not believe in the procedure. Another one also told me that her nephew had been inoculated at the time he reached the age of 6 months, in part at least, because of her urging, although she said that 3 other babies who were treated at a clinic and who were children of her sister's close friends, had probably received the stimulus more from the direct publicity campaign of the health department than from casual association with members of the department staff. The clerical force and others in the department take a considerable interest in reading the texts of the weekly 5-minute radio messages, which are broadcast under the joint auspices of the City Health Department and the State Medical Society. A similar interest is taken in the monthly department publication known as *Baltimore Health News*, and in other printed material put out from time to time by the department. There is, however, a definite lack of planning for

staff education other than in the instances I have mentioned.

It would seem that health departments in this matter might well learn a lesson from the selling and advertising methods of certain big industries. During the recent years of depression, I am told that a large national electrical supply company made it clear to all its workers that they were potential salesmen and perhaps their jobs might depend on the efforts they put forth toward an increasing sale of the company's products. In the annual report sent to stockholders the company called attention to this effort of the employed staff and indicated that stockholders too might be better assured of continuing dividends should they purchase the products of their own company and mention them to their friends. I know that these efforts resulted in definitely increasing the business of the company and it would seem that it was an educational project which had certain similarities with the problem of selling health education to the staff members of a health department.

Perhaps imagination and initiative are all that are really needed if we are to dramatize to ourselves the possibilities in staff education. At the same time we should realize that a little scientific information, or perhaps misinformation, in the hands of untrained persons may not be without its dangers. Technics in public health education and in salesmanship and advertising are developing, if anything, a little more rapidly than they may be safely assimilated. However, I do believe we may well take a long range view of this matter and try to build in slowly a very firm educational foundation within our health departments.

Solid foundation-laying is excessively time-consuming. Anyone knows this who has watched the demolition of an old building and the preparation for a modern skyscraper. The ancient Vishnu

schists, the rock foundation lying at the bottom of the Grand Canyon, are over 1,000 million years old. The tremendous earth changes that have taken place in the Canyon area, some of which have left no visible trace of themselves, impress one with two quite conflicting thoughts:

The first is the apparent futility of our pigmy-like human efforts in a civilization which itself is the thinnest of veneers on our ageless organic and inorganic inheritance, a civilization which is constantly showing an aptitude for self-destruction; the second is the imperative nature of some inner urge

which drives us on to do our utmost, in spite of this seeming futility.

The record of the rocks is clear. Foundation-laying, then, in health education as in other fields takes time, and patience, and more time—with a deal of thinking interspersed as an essential mortar if solidity is desired. We should, even at best, expect mighty and unpredictable forces which will warp, twist, uplift, or flatten out our best efforts. Yet, without taking ourselves too seriously, and conscious of the age-old time-relationships as we see them all about us, each one of us must go on and do his best, and each one in his own way.

Hospital Survey for New York

A HOSPITAL survey for the New York Metropolitan area, sponsored by the United Hospital Fund, and provided for by a grant from the Carnegie Foundation, has been put into the hands of Dr. Haven Emerson, as Director of Studies, and Dr. Gertrude Sturges, as Assistant Director, with Dr. George E. Vincent as Chairman of the general Survey Committee of leading citizens, and David H. McAlpin Pyle as Vice-chairman. The actual prosecution of the work will be in the hands of a study committee composed of the following persons:

S. S. Goldwater, M.D.
Charles Gordon Heyd, M.D.
John E. Jennings, M.D.
Eugene H. Pool, M.D.
Willard C. Rappleye, M.D.
Nathan B. Van Etten, M.D.

The area includes, as well as the City of New York, the Counties of Westchester and Nassau in New York, the towns of Greenwich and Stamford in Connecticut, and all of Essex, Hud-

son, and Union Counties, and parts of Bergen and Passaic Counties in New Jersey, comprising an area of 1,535 square miles and a population as of 1930, of 10,247,895.

The survey will include in addition to its study of hospitals, a study of the 6 accessory activities in the field of organized care of the sick, as follows: Out-patient services, convalescent homes, Institutions for the chronically sick, Visiting nursing, Medical social service, and Domiciliary medical care.

A feature of this study upon which special emphasis will be placed, is the financial statements of these assembled public utilities, not only from the point of view of the current or annual balance sheet, but in the form of a stockholders statement of the total investment in land, buildings, endowment, etc. It is hoped that on the basis of this survey an approximate estimate of the projecting needs of the 18 million people who will be occupying this area in 1965 may be described.

Routine Use of a Modified Eijkman Medium in the Examination of Oysters, Crabmeat, and Other Substances

C. A. PERRY, Sc.D., F.A.P.H.A., AND A. A. HAJNA

Bureau of Bacteriology, Maryland State Department of Health, Baltimore, Md.

THE Eijkman test for *Bacillus coli* has been used and studied in the laboratories of the Bureau of Bacteriology of the Maryland State Department of Health since 1929. One of the authors (Perry, 1929), first applied the test to a number of cultures of *Bacillus coli* recovered from oysters and oyster bearing waters. He found "such cultures invariably produce indol from a suitable medium and were able to ferment the dextrose of Eijkman broth with gas at 46° C." He also found that "only 11.2 per cent of 223 cultures of lactose-fermenters (coli-aerogenes group) from oyster and water samples from four areas were *Bacillus coli*. The four areas differed geographically, topographically, and in respect to their sanitary features. The presence of *Bacillus coli* was found in close agreement with probable fecal pollution."

In Maryland, a systematic study of oyster producing waters and the oysters themselves has been in progress since 1925. It became obvious from these studies that an evaluation of the coli-aerogenes group content of oysters is of little, if any, practical value (Perry, 1928). While considerable difference of opinion exists among bacteriologists and others whether *B. coli* or the coli-aerogenes group should be used as an index of pollution in drinking waters, in the field of fecal pollution in oysters and

oyster waters the coli-aerogenes group has been found unsatisfactory as it gives information of little if any value for oysters and of comparatively less value than *B. coli* for oyster bearing waters. For the past year (1934), determinations of the *B. coli* content (score and probable number) of oysters using the modified Eijkman medium of Perry and Hajna* (1933), and standard lactose broth (American Public Health Association) have replaced those of the coli-aerogenes group. As yet, no attempt has been made to correlate these data with pollution. Most of the samples have been taken from waters free of any significant fecal pollution and the *B. coli* scores of the oysters usually have been very low. While the coli-aerogenes group has been much more satisfactory as an index of possible fecal pollution of oyster waters than of oysters themselves, it has not been entirely satisfactory even for oyster waters. The coli-aerogenes group content of many waters of unquestionable purity, from the standpoint of growing oysters, has

* Modified Eijkman Medium †

Peptone (Difco)	15 grams
K ₂ HPO ₄	4 grams
KH ₂ PO ₄	1.5 grams
NaCl	5 grams
Dist. water	1,000 c.c.

† If inoculum is by loop or needle, use formula as given. If by pipette, adjust so that final concentration with inoculum will be given.

been far in excess of the amount permitted by the Drinking Water Standards of the U. S. Public Health Service. This experience indicates that *B. coli* would be a much better index of fecal pollution for both oysters and oyster waters than the coli-aerogenes group. The writers also believe that *B. coli* would be just as superior to the coli-aerogenes group as an index of possible fecal pollution when applied to drinking waters.

The Eijkman test has, we believe, many practical advantages as a presumptive test for *B. coli* in oysters, water, crabmeat, and other substances. These advantages have been given by Leiter (1929) and others. That the original Eijkman medium (1904) was not entirely satisfactory has already been pointed out by the authors (1933). More *B. coli* was recovered from fresh human feces using the modified Eijkman medium referred to than could be recovered with lactose broth. In this paper, data are presented on the practical application of this test to samples of oysters, water, crabmeat, etc.

METHOD OF EXAMINING OYSTERS, ETC.

The method of examination was as follows: Five tubes of each medium (modified Eijkman medium and Standard lactose broth) were inoculated with like amounts of water, oyster shell liquor, etc. In the case of oysters, 5 tubes were inoculated with 1 c.c. each of oyster shell liquor and 5 with 0.1 c.c. (1 c.c. of a 1 in 10 dilution). In most water samples, 5 tubes were inoculated with 10 c.c. each, and 5 with 1 c.c. each. The amounts of other substances used varied according to experience but like amounts were used for both media except where noted. Lactose broth tubes were examined according to Standard Methods of Water Analysis of the American Public Health Association while the method used for the Eijkman broth tubes was that described by the authors (1933).

COMPARATIVE NUMBER OF TUBES AND SAMPLES OF OYSTERS, CRABMEAT, AND WATER IN WHICH FERMENTATION AND CONFIRMATION FOR BACILLUS COLI AND COLI-AEROGENES GROUP OCCURRED FOR EIJKMAN AND LACTOSE BROTH

In Table I comparative data are given for the number of tubes of Eijkman and lactose broth, inoculated with equal quantities of shell liquor from oysters, crabmeat, and water, in which fermentation and confirmation for *B. coli* and other coli-aerogenes organisms was made. On the basis of these data, the following deductions may be made.

The modified Eijkman medium is more selective and efficient for the isolation of *B. coli* than lactose broth. Approximately 6.4 per cent of the lactose broth tubes inoculated were confirmed for *B. coli* while 8.9 per cent of the inoculated Eijkman tubes were confirmed for *B. coli* in spite of the fact that nearly twice as many of the lactose broth as of the Eijkman broth tubes showed gas fermentation. Over twice as many of the Eijkman tubes as of the lactose broth tubes inoculated from oysters and crabmeat were confirmed for *B. coli* while a slightly larger per cent of the standard lactose broth tubes inoculated from oyster waters were confirmed for *B. coli*. Of the lactose broth tubes with gas 18.7 per cent were confirmed while 54.3 per cent of the Eijkman tubes were confirmed.

Since the Eijkman test has been designed to eliminate members of the coli-aerogenes group not *B. coli* it should be expected that many less confirmations for this group would be made from the Eijkman broth tubes. Accordingly, 27.6 per cent of the lactose broth tubes were confirmed for members of the coli-aerogenes group against 14.1 per cent of the Eijkman tubes. These figures include *B. coli* of course. The percentage of non-*B. coli* members of the coli-aerogenes group are 21.2 for

* Determinations made on 88 samples in lactose and 229 in Eijkman broth

† Determinations made on same samples for lactose and Eijkman broth

lactose broth and 5.2 per cent for Eijkman broth.

Gas was present in about twice as many (34.4 per cent) lactose broth as Eijkman broth tubes (16.4 per cent). Of standard lactose broth tubes inoculated with liquor from shucked oysters, gas was present in 48.7 per cent against 19.2 per cent of the Eijkman tubes. Of the oyster water samples, 26.3 per cent were found to produce gas in standard lactose broth against 12.6 per cent in Eijkman broth, while gas was present in 31.0 per cent of the standard lactose broth tubes inoculated from crabmeat against 18.6 per cent of the Eijkman broth tubes. In routine laboratory work, it is not always possible to read gas production at exactly 24 and 48 hours. In many instances the 24 hours readings represent only 18 hours of incubation. If a full 24 hours incubation had been made, a much larger per cent of the Eijkman tubes doubtless would have been confirmed for *B. coli* and a much smaller residual number, consequently, would have been confirmed after 48 hours of incubation.

From these data, it is obvious that, using Eijkman rather than lactose

broth, a bacteriologist has only one-third the number of presumptive tests for *B. coli* to confirm. There is less work involved in confirming presumptive Eijkman tubes than presumptive lactose broth tubes, for on plates made from Eijkman tubes, *B. coli* is often the only organism present while on plates made from lactose broth tubes several organisms of the coli-aerogenes group are frequently present. This necessitates increased effort to select colonies of *B. coli* and to secure pure cultures. It is much more difficult to secure well isolated colonies from lactose broth tubes than from Eijkman broth. Only occasionally are plates, made from Eijkman broth tubes, overgrown. There is, therefore, less than half the work involved in using lactose broth for the routine isolation of *B. coli*.

PROBABLE NUMBERS OF *BACILLUS COLI* AND COLI-AEROGENES ORGANISMS FOUND IN OYSTERS, WATER, CRABMEAT, ETC., USING EIJKMAN BROTH AND STANDARD LACTOSE BROTH

The probable numbers * of *B. coli*

* Tables for Rapid Interpretation of Fermentative Tube Results, M. H. McCrady, *Pub. Health J.*, IX, 5 (May), 1918.

and coli-aerogenes group organisms in oysters, crabmeat, oyster waters, milk, ice, sewage, and eggs were determined. These data are presented in Table II. *B. coli* was identified in the same manner as already described. In the last column of Table II are given the ratios of the probable numbers of *B. coli* as determined using Eijkman broth to the numbers as determined using standard lactose broth and in proportion to coli-aerogenes organisms as determined using the standard procedure of the American Public Health Association. While these ratios indicate that the Eijkman method, as used, was only half as efficient in detecting the probable numbers of *B. coli* from oysters, salt water from oyster areas, and milk as standard lactose broth, this is not really true. Much of the data prepared in Table II was collected before certain refinements in the Eijkman test were used. It will be observed, for instance, from Table I, that over twice as much *B. coli* was isolated from oysters using Eijkman broth as in using lactose broth. In our earlier work on fresh human feces (1933 results confirmed by recent work) more *B. coli* was isolated using Eijkman broth than by using standard lactose broth. The number of samples of ice, eggs, and sewage is too small to be of much significance, especially since these observations like-

wise were made before improvements in the Eijkman method had been applied.

A most significant point is the tremendous difference between the average number of *B. coli* in 83 samples of oysters and the average number of coli-aerogenes group organisms. With coli-aerogenes organisms outnumbering *B. coli* 50 to 100 times (depending on the method), comparatively small variations in the probable numbers of *B. coli* as determined by the two methods becomes of comparatively less significance. In oyster waters, the ratio of coli-aerogenes organisms to *B. coli* was 3 to 5 times as great. This is what those with experience in this type of work would expect. In crabmeat 4 to 7 times as many organisms of the coli-aerogenes group as *B. coli* were found.

To the writers, these data signify the tremendous error in trying to evaluate fecal contamination of oysters, in particular, on the basis of the coli-aerogenes group and indicate quite clearly the desirability of using *B. coli* generally as an index of fecal pollution.

SUMMARY AND DISCUSSION

A modified Eijkman medium with incubation at approximately 46° C. has been used for the routine examination of samples of oysters, crabmeat, salt water in which oysters grow, sewage, and other substances.

TABLE II

AVERAGE PROBABLE NUMBER OF *Bacillus coli* RECOVERED FROM OYSTERS, ETC., BY EIJKMAN BROTH AND LACTOSE BROTH AS COMPARED WITH THE AVERAGE NUMBER OF COLI-AEROGENES ORGANISMS FROM LACTOSE BROTH

Substances	Number of Samples	<i>Bacillus coli</i> *		<i>Coli-aerogenes</i> *		Ratio a-b-c
		Eijkman Broth (a)	Lactose Broth (b)	Lactose Broth (c)		
Oysters	83	3.5	9.1	362		1-2.6-103.2
Oyster waters (salt)	229	5.2	9.4	28.8		1-1.8-5.5
Water, fresh (heavily polluted)	11	431,634	107,582	1,109,514		1-0.25-2.6
Ice	6	270.8	1,483.0	1,512.5		1-5.5-5.6
Sewage	3	68,333.3	93,333.3	93,333.3		1-1.4-1.4
Eggs	2	14,000+	7,700+	14,000+		1-0.55-1
Milk	15	49.3	144.7	369.3		1-2.4-7.5
Crabmeat	135	628+	418+	2,741+		1-0.67-4.3

* Probable Numbers per 100 gm.

NOTE: Acknowledgment is made of examinations by bacteriologists as follows: A. A. Hajna 123, H. B. Robinson 192, J. H. Dingle and A. A. Hajna 117, T. F. Dozois and R. T. Humiston 25, S. R. Pence 20, C. A. Eddy 7.

The presumptive and confirmed tests for *B. coli* (so-called fecal type) and organisms of the coli-aerogenes group were made on 182 samples of shucked oysters, 344 samples of salt water from oyster areas, and 307 samples of crabmeat. In this work the term "presumptive" refers to any amount of gas produced in either lactose broth or dextrose (Eijkman) broth. In regard to the shucked oyster samples, approximately 3.9 per cent of 2,195 inoculated lactose broth tubes confirmed for *B. coli* against 9.3 per cent of the same number of tubes of Eijkman medium. Of 3,239 and 3,233 tubes of lactose and Eijkman broth respectively inoculated with salt water from oyster areas a little over 2 per cent more of the lactose broth tubes than the Eijkman broth tubes (8.79 and 6.59 per cent respectively) confirmed for *B. coli*. Of 166 samples of crabmeat inoculated into lactose broth 5.1 per cent of the tubes were confirmed for *B. coli* against 11.2 per cent of 307 samples inoculated into Eijkman broth. On the whole, gas was present in less than half as many Eijkman tubes as lactose broth yet more (2.5 per cent) *B. coli* was recovered from the Eijkman broth tubes than from lactose broth tubes, thus establishing the superiority of the Eijkman method under the circumstances noted.

In another series of samples the probable numbers of *B. coli* isolated from Eijkman broth and lactose broth were compared with the numbers of organisms of the coli-aerogenes group. The data given in Table II were collected in the earlier part of this study when an incubator temperature of approximately 46° C. was used. The variations are believed to be due to a different bacterial flora in these samples which tend to suppress *B. coli* in the Eijkman medium. On latter samples a tube temperature of 46° C. rather

than an incubator temperature of 46° C. was used and more *B. coli* was then recovered apparently, by the Eijkman test than by lactose broth. Such a tube temperature was used in some of the 182 samples of shucked oysters in Table I. In 135 samples of crabmeat and 2 samples of eggs the estimated probable numbers of *B. coli* isolated by the Eijkman method were nearly twice those isolated from lactose broth, while in 11 samples of heavily polluted water 4 times more *B. coli* was isolated from Eijkman broth than lactose broth. In 83 samples of oysters, 6 of ice, 3 of sewage, and 15 of milk greater numbers of *B. coli* were isolated from lactose broth tubes; in oysters (shell) 2.6 times as much, in salt waters from oyster areas 1.8 times as much, in ice 5.5 times as much, in sewage 1.4 times as much and in eggs 2.4 times as much.

The opinion of the authors from their rather extensive experience, is that the Eijkman test, properly adjusted, is a valuable presumptive test for *B. coli* which organism they believe should be the one generally used as an index of fecal contamination of oysters, crabmeat, water, and other substances.

The Community Program of Health Education*

C. E. TURNER, DR.P.H., F.A.P.H.A. (*Life Member*)

*Professor of Biology and Public Health, Massachusetts Institute of Technology,
Cambridge, Mass.*

THE health education of an individual is not restricted to those words either spoken or written which are specifically directed toward him for that purpose any more than his character is completely determined by what he hears in church. One's ethical behavior and one's health behavior are both determined in large measure by the customs and practices of the race, the community, and the family. The child gradually recognizes and begins to participate in these practices. Standards of honesty and cleanliness are set by the attitudes and behavior of family and associates more than by theoretical considerations of ethics and hygiene.

The realization of these facts tells us two things: (1) All the experiences of the individual must be considered in determining the nature of his health education. (2) Health education to be most effective must address itself to the whole community rather than to a single group or a single age level. Let us consider the health education activities of the school, the health department, and the private health agency.

THE SCHOOL

The public school recognizes that it affects the health education of the child

through all of his experiences at school and through those health experiences outside of school which are initiated or modified by school activities. This means that the school is concerned not only with health instruction and with training in hygienic living while the child is at school, but also with the child's experiences in having physical defects corrected, and in maintaining and improving his health practices in the home, in so far as the school can beneficially influence these experiences.

The school contributes to the health education of the pupil in two essentially different ways: (1) through direct health training and instruction, (2) through those school activities which form a part of the child's health experience. Let us review briefly the scope of each of these two phases of the health education program.

A. DIRECT HEALTH INSTRUCTION AND TRAINING

1. *Direct Instruction in Hygiene*

The oldest and most universally recognized phase of health education is instruction in hygiene. When the child enters the public school he is under the authority of the home and school and his health habits reflect direct training. When he leaves the public school he is about ready to leave the authority of the home also and his health behavior must be supported by a knowledge of

* Read at a Joint Session of the Public Health Education and Child Hygiene Sections of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

the facts of hygiene. We must begin with health training and gradually through public school experience we must place a foundation of knowledge beneath these health practices which will support them with wise and intelligent adaptations in the years to come.

In the first 3 grades the knowledge content of the program is relatively unimportant and no formal or set health instruction need be prescribed. Beginning with grade 4 and continuing to the end of junior high school, the present tendency is to provide specific instruction for at least 2 class periods a week with a program which is sufficiently different and new in approach each year to make the subject, with its necessary repetitions, fresh and interesting to the pupil.

For example, in grade 4 the child may be chiefly concerned with "What is health training," or the way in which the detailed rules of the health game are carried out. In grade 5 he may be interested in "Why these health practices are desirable." In grade 6 he studies biological cleanliness and its relation to the health of the individual and the family. In grade 7 he studies community hygiene, in grade 8 elementary descriptive physiology and in grade 9 physiology and foods with home nursing for the girls and first aid for the boys.

In the senior high school there will be some direct health instruction, but it is doubtful whether a regular period for informational hygiene should be assigned throughout these 3 years. It may be better to contribute to health instruction through other subjects, particularly science, social science, and biology, and to have a single course in health problems for those high school seniors who are not going to college. Training in physical education has an increasing influence upon the maintenance of healthful living as the child advances in the grades.

It must not be thought that the class-

room period of health instruction is restricted to the presentation of information. It is used to provide an opportunity for centralizing all educational activities. Through it pupil activities of vital interest are developing and in it health experiences are reviewed.

2. *Integrated Health Instruction*

In addition to the regularly organized instruction in hygiene, health is taught to a considerable degree in connection with the teaching of other subjects. This may be done by using health facts in connection with such subjects as art, arithmetic, and geography, or by integrating health with the other subjects in units of work where the partitions between the different subjects have been removed.

It has occasionally been urged that complete health instruction could be developed in this way, but authorities now generally agree that direct instruction is needed and that integration is more successful with direct instruction than without it.

3. *Health Training Through Watching Growth (Monthly Weighing)*

Regular and continued growth is a sign of health and the child who is interested in growing is willing to follow those health practices which will help him grow. Monthly weighing has come to be a valuable means of health training.

4. *Health Training Through Inspection and the Recording of Health Practices (Morning Health Review)*

The training of the pupil is effectively developed by the regular checking of cleanliness and neatness and by keeping records for short periods of the success of the class in maintaining different health practices. For this reason it has become a nearly universal practice to use a few minutes at the opening of school in the morning for purposes of health training.

These are the 4 important procedures

in direct health training and instruction. Let us now consider those other activities of the public school which affect the child's knowledge but more specifically influence his attitudes and practices.

B. OTHER SCHOOL ACTIVITIES WHICH
DETERMINE IN PART THE CHILD'S
HEALTH EXPERIENCES

*1. The School Presents Its Program
to the Home*

The school has a program of instruction and standards of behavior which the child is expected to meet. Parents want to know what the program and standards are and what progress the child is making in the different problems of behavior and in the different subjects of instruction. The school tells them what it is trying to do from year to year in the health training of the child. The activities of the school in establishing home and school relationship and coöperation directly affect the pupil's health experiences.

2. Health Examinations

Health examinations should be essentially educational in nature and not merely free medical or diagnostic service devoid of educational value. Here the child comes to see the limitations of his bodily mechanism and here he learns from a new angle the relationship between his health and his health practices. Here it is that the child should learn to appreciate scientific medicine and the service of the medical profession in such a way that he may be willing to make a wise use of medical service throughout adult life. If this one objective of the school health program were reached it would open the door to unlimited opportunities for health improvement through medical service.

3. Correction of Physical Defects

This activity is a continuation of the processes which began with the health examination, and the pupil's experience will definitely affect his willingness to

secure medical assistance in the future and his attitude toward physicians, clinics, hospitals, and care of his body.

4. Communicable Disease Control

The school is primarily concerned here with the prevention of disease, but the actual situations which arise in the school in connection with this activity provide better teaching opportunities than can be found in the theoretical discussion of disease, because they are related to actual experience.

5. Physical Education

The physical activities of children contribute to health directly but physical education also contributes to general education. It aims to train the body in posture and bodily mechanics; to establish a fondness for games, big muscle activity, and habits of regular exercise; to provide relaxation in the school day; to develop special skills; to correct marked defects of posture through work with individual children; and to contribute to personality, social adjustment, character, and mental health. Success in these activities serve as one measure of health, and the desire to succeed in physical accomplishment is an incentive to the development of health habits.

*6. The Maintenance of Hygienic
Conditions in the School Building*

The hygienic condition of the school plant tells the child whether the school authorities really believe in the principles of sanitation which they teach. It accustoms him to good or poor standards as the case may be. The cleanliness, ventilation, lighting, and seating, together with proper provision for supervision of toilets and bubbler fountains, contribute to the health education of the child.

7. School Lunch

The mid-morning lunch and the noon lunch, where the latter is taken at school, provide definite opportunities for health training in the selection of food and in the hygiene of eating.

8. *Hygienic Arrangement of the School Program*

More and more attention is being given to the effect upon the health of the pupil which is produced by the way in which the general school program is conducted. The type of instruction and the attitude of the teacher toward the pupil have definite effects upon his mental health. The length of the recitation period, the provision of brief periods of relaxation, the sequence of studies, the nature of discipline and punishment, the number of pupils in a room, the nature and conduct of examinations, the extent of extracurricular activities, and the wise selection of textbooks or source materials, all have an effect upon the health of the child and upon his standards of conduct.

A wider recognition of the nature and breadth of the school health education program will eventually lead to its proper supervision and to the coördination of the various activities from the viewpoint of health education.

THE HEALTH DEPARTMENT

The important health education program of the health department is not as uniform in its operation or as easy to describe as that of the school department. It is possible to indicate the health education responsibilities of the health department and the tools or agencies through which it may operate.

The responsibility of the health department for educational activities may be divided into four parts:

1. To keep the public informed concerning the work, the services and the needs of the health department in order to maintain the public support which a service agency of the government needs in a democracy.
2. To instruct special groups, such as food handlers or householders, and the public generally concerning those procedures involved in the prevention of the spread of communicable disease.
3. To promote hygienic living on the part of the general population through educational activities of various sorts.

4. To assist the health education program in schools by supplying health information concerning the city or county, and in helping to arrange field trips for older pupils to demonstrate the activities of the health department.

The health-education activities of health departments may be:

1. Through direct individual health instruction by employees, such as physicians, nurses, and sanitary inspectors, in the conduct of their duties.
2. Through providing or arranging for instruction of small organized classes in such subjects as home hygiene, the care of the sick, first aid or the care of children.
3. Through providing speakers by means of an organized speakers' bureau, operated in coöperation with the medical and allied professions.
4. Through newspaper publicity, involving news items, feature stories, and editorials.
5. Through the radio.
6. Through printed matter, including reports, bulletins, leaflets, pamphlets, handbills or form letters.
7. Through various types of visual instruction, including moving pictures, posters, demonstrations, exhibits.
8. Through the educational use of health surveys.
9. Through the direct instruction of food handlers yearly when each receives his card.

PRIVATE AGENCIES

The private agencies have essentially the same health education tools with which to work as does the health department. The personnel is varied but includes the medical staff of medical institutions, the nursing staff of medical and nursing organizations and health educators in medical institutions, tuberculosis associations, and social agencies, particularly those working with young people.

We cannot describe here the many varieties of national, state, and local agencies contributing to the public health. Their educational services lie mainly in two fields: (1) the promotion of new health activities and the development of public support for them; (2) the development of educational

activities in the field of special interests in order to secure more rapid advancement in this field than would otherwise be possible. These agencies develop support for the health department and the school health program. They often stimulate and make possible more effective health work on the part of the official agency.

We need, and we shall ultimately develop, standards and methods of measurement of the quantity and quality of health education activities. At present the school health program has made more progress in this direction than has the program of popular health instruction.

We have seen 3 different phases of

the problem of health education for the community, and we recognize that there are different technics involved in the 3 types of activity. How can the activities of the health department, the school department, and the private agencies be welded into a unified program of health education? It may be that there will eventually evolve some plan for the use of a specialist in health education who can serve all these different groups.

At present the most feasible development is, perhaps, the health education council in which all of these groups are represented and through which the various phases of the program may be interrelated.

Schick Reaction

IN a study of the relation of the Schick reaction to antitoxin titer,¹ 47 military recruits were tested with 2 dilutions of Schick toxin, one 1-600 and one 1-300. A second toxin was also used, dilution 1-500, and for all the dose given was 0.1 c.c. Estimations of blood antitoxin were made by Ehrlich's guinea pig method. Only those negative to 1-300 dilution had more than 1/30 unit antitoxin per c.c. in blood. Those negative to 1-600 and 1-500, yet positive to 1-300, had less than 1/30 unit, and often as low as 1/60 unit. A negative test with usual dilution does not correspond with 1/30 unit per c.c., the

amount generally considered requisite to give sure immunity.

In a later study² the authors have attempted to determine the effect of intercurrent infective diseases on the Schick reaction. In a study of 54 cases it was found that an attack of influenza may lower the immunity against diphtheria and the authors suggest this as an explanation of the severity of diphtheria when complicating influenza. According to a number of authors, measles has no effect in lowering the immunity against diphtheria.

Chlorination of Los Angeles Water Supply*

R. F. GOUDEY

Sanitary Engineer, Bureau of Water Works and Supply, Los Angeles, Calif.

LOS Angeles has the distinction of being one of the few cities having no sewage laden streams or lakes tributary to its water supply. Chlorination is practised entirely as a precautionary measure for protection from various but important seasonal factors. Particular problems are recreational use of remote watersheds, effective storage for distribution, contamination from seagulls and other birds, safeguarding of local gravity conduits, large and sudden variations in flow due to irrigation demands, and isolation of treatment plants because of great distances separating them. Special developments include automatic chlorination, intermittent treatment and a coördinated system of control.

The chief water supply of Los Angeles is from the Owens River Aqueduct, itself over 250 miles in length and which drains the east slope of the Sierra Nevada range from Mt. Whitney, the highest point in the United States, for a distance of 150 miles north to Mt. Lyle, which is farther north than San Francisco. The snow capped Sierra peaks and glacial laden crags at elevations of 9,000' to 14,000' constantly feed alpine streams with water of pristine purity.

In the Mono and Inyo National Forest during each summer season nearly a million hikers, campers, fishermen, and hunters use the watershed. The maximum recreational use has been facilitated by excellent highways leading to extensive mountain roads and trails, organizations of pack train outfits, and regular airplane transportation to 5 mountain landing fields. On its way to the desert are meadows, flats and valleys which likewise are used for recreational purposes. The average elevation of the desert floor at the foot of the mountains and above the intake is about 4,000'. The aqueduct not only collects the mountain streams but also springs which emerge at the base of mountains and the drainage from the valley floor. There is some grazing of cattle along the lower slopes of the mountains and there are 4 small towns on the valley floor widely separated. The resident population on the watershed is 1.8 persons per square mile.

As might be expected, bacteriological samples of the supply at the aqueduct intake showed the presence of slight contamination but only to the extent of 25 per cent of the samples with 3 or more tubes positive and 30 per cent of 10 c.c. portions positive. Since no sewers discharge into any of these streams it becomes apparent that very few large cities have supplies with as low a contamination.

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

The aqueduct collects the entire flow of the Owens River which formerly discharged into Owens Lake. It starts out as an unlined canal, changes to an open concrete channel, and enters Haiwee Reservoir 60 miles below the intake. Haiwee Reservoir is made up of 3 narrowly connected sub-reservoirs giving effective storage of 6 or more weeks, which apparently removes a large portion of the bacteria entering with the aqueduct. There is no resident population on the watershed nor is hunting or fishing allowed. It is a cold, bleak location in the winter and is scorching hot in the summer. Bacteriological analyses indicate that the supply at the outlet of Haiwee Reservoir meets U. S. Treasury Department Standards. In fact, during the past year there were no samples having 3 or more 10 c.c. tubes positive, and less than 2 per cent of the 10 c.c. portions were positive.

The aqueduct from Haiwee to Fairmont Reservoir, 140 miles downstream, is covered, with no opportunity for surface or other contamination to enter. Fairmont Reservoir, likewise located on the desert, has no resident population or recreational use. It is at elevation 3,000' and supplies power plants in San Francisquito Canyon which in turn discharges into Dry Canyon Reservoir, still outside the City of Los Angeles. There is no opportunity for contamination of the supply at Fairmont or Dry Canyon Reservoir except through birds.

The main aqueduct supply in Dry Canyon feeds Upper and Lower San Fernando Reservoirs. A portion, however, is diverted above Upper San Fernando Reservoir through the Maclay High Line to the northeast side of San Fernando Valley. This supply is continuously chlorinated with 2 automatically operated chlorinators treating flows varying from 6 to 60 second feet. It has water injector pumps in duplicate with a gas engine pump standby. The Maclay High Line is a

gravity conduit and chlorination is necessary to counteract any seepage which may enter it from local sources as well as to overcome contamination likely to enter at Dry Canyon and Fairmont Reservoirs. It is proposed in the future to install ammoniation equipment on this line to carry residual chlorination to its terminal reservoir.

Upper San Fernando Reservoir has a watershed of about 9.0 square miles with less than 0.3 persons per square mile. A railroad crosses the north side of it. This reservoir is subject to contamination following periods of heavy rainfall from surface run-off occurring on the average of about 2 weeks out of the entire year. Chlorination is admittedly important during such times. The supply from Upper San Fernando divides, one portion going directly to Lower San Fernando for delivery to the main portion of San Fernando Valley and the city proper, and the other through a high line on the northwest side of San Fernando Valley leading to Chatsworth Reservoir. Water is used directly out of this line and consequently is continuously chlorinated at the Chatsworth High Line station. A third chlorination station is located at the outlet of Lower San Fernando Reservoir.

GENERAL LAYOUT OF CHLORINATOR STATIONS

In all, the city has installed 15 chlorination stations, although the number now in operation is 8. It has had as many as 31 vacuum automatics in operation at one time. The Mechanical Engineering Division has worked up a schematic arrangement for varying degrees of automatic control from Venturi or Pitot tubes. Features of the Los Angeles practice include: (a) cranes for ton containers; (b) a drip pan under the ton containers in which water is circulated from the tray to collect moisture from the sides of the container, prevent it from running into the scale

pans, and provide the necessary latent heat for evaporation of chlorine at lower temperatures; (c) water injector to carry waste gas from cylinders into the sewer; (d) differential converters from Venturi control leads converting positive pressures into corresponding vacuums; (e) connections to water leg on gas orifice to vary chlorine feed; (f) gas regulation valves; (g) a direct low voltage system with necessary relays and switches to cut chlorinators in and out to keep in step with the flow to be treated; (h) water injector supply automatically operated and in duplicate with a gas engine driven pump for automatic emergency use; and (i) manifold chlorine application points.

CHATSWORTH HIGH LINE CHLORINATION STATION

The Chatsworth High Line station consists of four 300 lb. machines where the flow in a gravity conduit varies from 9 to 90 second feet. All the piping arrangements are overhead—black iron pipe is used for chlorine lines, and hard rubber pipe for solution lines. The chlorination solution is discharged into the gravity conduit at 3 points. In the second room of this station is located a device designed and constructed by the department which converts float elevations in the conduit to vacuum differentials which operate the chlorinators. Electrical equipment changing the number of chlorinators in operation and injector pumps is located in the same room. The injector pumps are in duplicate with a 3rd gasoline unit which operates either when the electricity goes off or the pressure in the injector water has decreased below an operating limit.

Water from the Chatsworth High Line discharges into Chatsworth Reservoir where the storage capacity is sufficient for over a year. This reservoir is fenced and although a chlorinator station is constructed at the outlet it has never been found necessary to use it.

SAN FERNANDO CHLORINATION STATION

The 2 main lines from Lower San Fernando Reservoir, 54" and 72" in diameter, respectively, are treated at 1 station. There are 8 machines with a chlorine capacity of 2,000 lb. per day. The combined flow in both lines is 329 second feet. This station was constructed in 1925 and is automatic. On the lower floor are the duplicate water injector pumps and a standby gasoline driven injector pump for the purpose of operating when the power is interrupted. This emergency unit has actually performed on a number of occasions during serious power interruptions. Converter equipment is located likewise in the basement. Storage in Lower San Fernando Reservoir amounts to 30 days or more and it is rare when the water needs to be treated. As a matter of precaution, however, it is operated continuously during the winter and 30 days following the last rain of the season. There is a saving of \$1,000 a month when chlorination is discontinued at this station, although this monetary consideration has no influence whatever on when the plant runs or is shut down.

AQUEDUCT CITY SUPPLY

The main supply for the city proper after leaving the chlorination station at Lower San Fernando is conveyed across San Fernando Valley to reservoirs on the mountains south of San Fernando Valley and north of the city proper. Stone Canyon Reservoir is the most westerly terminal reservoir. It has a storage capacity sufficient for over a year. No one lives on the watershed, and it still has the indigenous shrubbery on it. A chlorination station was located at the outlet but has not operated for 2 years because the water, even during storms, complies with the Treasury Department Standards.

A second terminal reservoir system is Upper Franklin and Lower Franklin Reservoirs. Upper Franklin Reservoir

is small, there being practically no storage, and although it is surrounded by a complete drainage system there are times during heavy run-offs when its capacity is exceeded. Lower Franklin Reservoir is adequately protected against surface water along the west margins and the drainage area above the reservoir. A chlorination station is located below this dam and is operated during the rainy season to take care of possible contamination which might enter the barren slopes on the east side of the reservoir.

A third terminal reservoir system for the aqueduct is in Upper and Lower Mulholland Reservoirs back of Hollywood. A chlorination station of the most recent design has been constructed to treat water from both reservoirs. It is a 2 story building, the upper floor being divided into 3 rooms. The first is for chlorine cylinders, scales, and the operator's desk. It is equipped with drip pans and blow-off lines. The second room contains the 5 fully automatically operated chlorinators, with flexibility of operation by any chlorinator to any of the 3 lines to be treated. The converters are located in this same room on the other side from the scale beams. In the third room are the duplicate injector pumps, electrical control devices for automatic operation, and the Venturi meters. In the basement are the Venturi tubes and the manifolds through which chlorine is applied at 9 different points from a hard rubber header into the water lines. The efficacy of this method for applying chlorine has also been proved at the Franklin Canyon chlorination station.

Intermittent operation of the chlorinator at Franklin and Mulholland Reservoirs, together with the discontinuance of chlorination at Stone Canyon, has proved satisfactory in that at all times the water as delivered to the consumer meets the Treasury Department Standards. Bacteriological sam-

ples for the past year of the aqueduct supply in the city proper indicate 1.95 per cent of the 10 c.c. tubes as positive, and 0.80 per cent of the samples show 3 or more tubes positive.

LOS ANGELES RIVER SYSTEM

One-fourth to one-third of the city's supply is still derived from the original source before the time of the aqueduct, consisting of wells and galleries in the Los Angeles River at the mouth of San Fernando Valley. One gallery has a $4\frac{1}{2}$ mile gravity conduit leading to Silver Lake Reservoir and $2\frac{1}{2}$ miles additional gravity conduit leading to Elysian Park Reservoir. The second gallery, known as Crystal Springs, has 4 miles of gravity line leading to Buena Vista Reservoir and an additional length of 2 miles to Bellevue Reservoir. In 1919 both galleries were equipped to take in surface water from the Los Angeles River. Chlorinators of a now obsolete type were installed at that time but in a very crude manner.

Chlorinators were later installed at the inlet of Bellevue and at the outlet of Silver Lake Reservoir. The gravity conduits for the most part follow hillside locations, but in other places pass through paved streets where sewers cross over or under. Bellevue, Silver Lake and Buena Vista Reservoir have now been protected against surface run-off and the conditions now on the Los Angeles River system are entirely different from those formerly existing. No surface water is taken and the raw water from both galleries is clear and safe. Manual chlorination equipment near the upper ends of both galleries was installed in 1930 but residual chlorine carried only 1,500' below. It was found that slight contamination was entering between the chlorinators and the terminal reservoirs. In 1933 the River Chlorination Station was converted into a full automatic ammoniation and chlorination plant with marked results.

The station is located where both lines come near together, one is automatically operated from Pitot tubes for both the chlorinator and the ammoniator, and the second is operated from vacuum differentials produced by a mechanism operated by a float in the gravity conduit. Residual chlorine is now carried to all the reservoirs served by these gravity lines. It has permitted the total discontinuance of chlorination at the Bellevue and Silver Lake Stations. Bacteriological analyses of the treated river supply show 0.69 per cent of the samples having 3 or more 10 c.c. tubes positive and 1.31 per cent of the 10 c.c. portions positive.

MISCELLANEOUS

The design of the buildings is an important feature. The first chlorination stations were merely shacks. The stations built since 1927 are permanent, substantial and artistic. Trucks with ton containers can drive back into the station and be unloaded with cranes. The older type of this station is typified by the abandoned station at Silver Lake.

In order to be able to treat reservoirs with chlorine a chlorine barge was constructed which could travel in 4 directions and diffuse chlorine solution as desired. This equipment is being tried out at Silver Lake about once a year in an effort to cope with algae which are not readily controlled by copper sulphate. It has not yet found a place in regular routine control.

The department maintains a portable chlorinator mounted on a trailer consisting of the following equipment: 1 vacuum-type chlorinator with full range of orifices, 10 h.p. gasoline engine, 30 gal. per min. pump, 220/440 volt motor, scales for chlorine cylinders, cooling facilities for chlorine tanks under high rates of chlorine withdrawal, a full line of hydrant pipe fittings, gages for water and gas pressures and gallons per minute pumped, and a series of hoods that are placed around the whole trailer while it is being hauled from place to place. This equipment has been successfully used in all emergency operations such as treating new mains when trenches have been flooded and emergency work during the Long Beach earthquake.

The department 2 years ago spent considerable time in testing out a residual chlorinator which automatically varies the flow according to the demand in the water as well as the varying flow. Considerable development needs to be done on such equipment but it is felt that the sooner it is perfected the safer and more reliable will chlorination be.

A special cabinet, consisting of orthotolidine standards using 100 c.c. matched Nessler tubes read against a blue light under white glazed glass of samples representative of 20 minutes contact between the time of chlorination and testing, enables the operator to get consistent results and vary the chlorine dose as required.

Discussion

S. M. DUNN

Bureau of Water Works and Supply, Los Angeles, Calif.

THE first practical installation of apparatus for the application of chlorine to domestic water in the United States seems to have been made about

1910. This was in the remote East and antedates the first installation on the Los Angeles system by approximately 5 years. This first installation on the

Los Angeles system was located on the Los Angeles River supply, and the equipment was of the dry gas feed type. As Mr. Goudey has mentioned, the installation was crudely made and the building was not elaborate, but it was of concrete construction, and owing to the newness of the process of chlorination and to the short period of development of the equipment, no large amount of money was spent on architectural embellishment. We must remember, however, that the site of this installation, which is now surrounded by a well kept park, was then covered by a wilderness of brush and could only be reached by several miles of damnably rough roads.

Owing to the lack of experience of the builders of the then existing chlorinating equipment—and the experience gained to date by some of the present builders does not seem to me to have been phenomenally productive of practical equipment—this early chlorinator soon developed a variety of ailments which the busy engineers of the department could not take time to diagnose or combat effectively. Consequently, this machine was replaced in 1920 by one of the pressure solution feed type, which was supplied with injector water from a gravity line and treated water in a gravity conduit.

In 1923 the first vacuum type machine was installed. This installation was made at the upper end of Lower Franklin Reservoir and the equipment was placed in a tile roofed concrete building of not entirely unpleasing appearance.

In 1925, 2 more machines of the pressure type were installed on the outlet from Silver Lake Reservoir. This reservoir was at that time an important storage unit, but was located in a rapidly growing district and was not then, as now, protected from surface contamination by barrier walls, fences, and adequate storm drains.

From that time on there has been

steady improvement, not only in the equipment available for installation but also in general elaboration of plant layout and in the buildings that have been provided by the department for housing the equipment. This improvement has synchronized quite closely with the general increase in understanding; not only here but in the water works field at large, of the importance of reliable chlorination as a safeguard to public health.

All of the later plants have been made fully automatic, not only to keep down labor expense but also on the theory that if chlorination is necessary at all every practical precaution should be taken to see that the application is continuous and accurate. As Mr. Goudey has stated, automatic control has been extended to include not only the chlorinators themselves but also the equipment for switching the machines and the pumps for supplying the injector water. However, it seems well to state that we are of the opinion that these latter elaborations are more fully justified than his statement that the equipment at Lower San Fernando had "actually operated" would seem to indicate. In fact, it has been found that at times of heavy rainfall, when the danger of surface run-off contamination is greatest, the gasoline engine driven injector water pumps are apt to operate because of failure of electric power. During the deluge of last New Year's Eve, the Maclay and Chatsworth Inlet plants, so equipped, were subjected to power outages of 140 minutes and 105 minutes duration, respectively, but there was no interruption in the application of chlorine.

Our experiments with the residual controller soon disclosed the necessity for more elaborate means for bringing about adequate distribution of the dose over the whole cross-section of the main at the application point, if the main exceeds 18" in diameter. The opera-

tion of this controller is based on the theory that the residual chlorine in samples taken from the main at a distance of 500' to 1,000' down stream from the plant can be used to initiate a sequence of control of the chlorinating equipment. At the plant where the experiments on this controller were made, either 2 or 3 application tubes were in use at one time, but it was found that with this small number the controller would shift almost continuously, when it was in working order, owing to the wide variation in the residual chlorine content of the water at the sample point. In fact, a series of samples taken in rapid succession with constant flow and dosage would show residuals running from zero to 0.5 p.p.m. A manifold connected to a total of 9 application tubes was then installed and it was found that the consistency of the residual readings was greatly improved with consequent improvement in the operation of the controller. The department now has on order another controller of this type, the design of which has been improved in a number of ways, with which we expect to get much more satisfactory results.

On the whole, our experience with chlorinating equipment seems to indicate that available equipment is not built in units of sufficient capacity and that the range of automatic control is much too limited. This latter deficiency makes necessary the installation of a multiplicity of units, and in some installations

where the flow varies over a wide range, the installation of auxiliary equipment to shift the load from one machine, or group of machines, to another. This added complication would be eliminated if the producers of chlorinating equipment would supply machines of larger capacity and greater range of automatic control.

This deficiency in capacity and range is well illustrated at the Chatsworth Inlet Plant, where it is not at all unusual for the flow to vary from 24 to 102 cu. ft. per second in one 24 hour period and the yearly range in flow is from 9 to 136 cu. ft. per second. To cover this range a total of 4 machines is required. The smallest of these has a maximum capacity of only 80 lb. of gas per day and can only treat flows up to 27 cu. ft. per second. The second machine has a capacity of 150 lb. and is used in the range from 27 to 56 cu. ft. per second. For the upper part of the flow range 2 machines with a capacity of 250 lb. each are used. A more ideal installation would seem to be one in which a single machine of sufficient range and capacity would be used to cover the entire range of flow with a duplicate unit for standby purposes. To produce such an ideal machine, however, an entirely new principle of operation will probably be necessary, but such a machine will no doubt follow the more general realization of the limitations of the equipment now available.

Individual Variations in Immunity*

HULDA E. THELANDER, M.D.

*Departments of Pediatrics and Communicable Diseases, Children's Hospital,
San Francisco, Calif.*

IN 1806 Thomas Jefferson paid the following tribute to Jenner: "Future nations will know by history the loathsome smallpox has existed and by you has been extirpated." Similar predictions have been made upon the discovery of protective immunization against other diseases. To date, however, our vital statistics still show deaths from smallpox, diphtheria, and typhoid fever. These smaller organisms, viruses, and bacteria, have not taken readily the path of the dinosaur to extinction.

Failure may be attributed to 3 main causes: (1) the high percentage of people who have not availed themselves of prophylaxis; (2) imperfections of the immunizing agents, and (3) individuals' failure to respond to immunization. This paper is concerned only with the third of these, namely the individual variations in immunity to disease.

The graded school system was designed originally to educate all children equally. It failed in part because children differ in ability to learn. Pediatricians compiled "age-height-weight" tables, but the combined efforts of mother, teacher, and doctor could not fit every child into its mould. It proved easier to suit the tables to the child.

A discussion then on differences in immunity should not be amiss.

Jenner recognized second attacks of smallpox. Authentic cases of second attacks of measles have been reported. In 1933 one of our medical students located 28 cases of adult pertussis most of whom had histories of previous whooping cough. With the aid of the cough plate the diagnosis is made more readily now than in the past. Patients who have recovered from diphtheria without treatment are not always immune to the disease. In poliomyelitis it has been found that individuals with severe paralysis may have less immune substance in the blood than normal adults or people with mild attacks of the disease.

Two procedures lend themselves readily to the study of individual differences in response to an immunizing agent, namely smallpox vaccination and diphtheria immunization.

In Peking, in 1927, 75 Westerners and 109 Chinese were vaccinated. This group could be observed carefully and histories of previous vaccinations readily obtained. There were a few unvaccinated people in the group and their takes, which were true primary takes, served as controls. It was found that 5 per cent of the Westerners had secondary takes indistinguishable from primary takes. The interval between takes varied from 1 to 20 years. Of this group, 9 gave a history of 2 takes, 2 of 3 takes, 1 of 4 takes, and 3 had

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 3, 1934.

scars from several takes. Others had reactions varying from typical immunity reactions to more marked vaccinoids. About 20 per cent showed degrees of poor immunity production.

Of the 109 Chinese vaccinated 9 per cent showed secondary takes equal to primary reactions, and 21 per cent showed poor immunity production. One of the Chinese with marked pocking had a typical take. Other individuals in the group of both foreigners and Chinese had never had anything but an immune reaction following an original primary take.

That these findings are significant has been demonstrated by Lennox¹ of the Peking Union Medical College. In his survey of the incidence of smallpox among missionaries in China he received reports on 111 cases with 28 deaths, and was able to get detailed reports from 30 families reporting 51 cases of smallpox. Fourteen of these were fatal and 37 recovered. One fatal case had been successfully vaccinated 3 weeks previous to his death. Of the 37 cases who recovered, 16 had been successfully vaccinated in the past; 4, more than 15 years previously; 3, from 5 to 15 years previously; 1, 4 years previously; and 3, 1 year previously. Twelve had been vaccinated once, 3 twice, and 1, 3 times. From his own figures and a review of the literature Lennox estimates that the chance of contracting smallpox after exposure is 18 in the unvaccinated to 1 in the vaccinated.

If we review our results in diphtheria immunization we will find a similar state.

New York observers found that approximately 88 per cent of adults in the city of New York were Schick negative without immunization. In rural New Jersey, on the other hand, only 29 per cent were Schick negative. For the past several years the medical and dental students at the University of California have been Schick tested and

have averaged about 30 per cent negative, showing a rural rather than an urban type of immunity. That they had an inherent capacity equal to the urban group was evinced when they were given very small doses of toxoid. Eighty-five per cent of the Schick positive group were Schick negative 6 months after 0.1 or 0.2 c.c. of toxoid in 2 or 3 injections at 2 weeks interval had been given. With very slight stimulation a figure resembling that in rural New Jersey was changed to a figure like that in suburban New York. Some of these positives were immunized by a repeat series, usually of larger doses. Everyone who has had experience with the immunization of adults, however, has found a certain percentage very resistant to immunization or readily reverting to the Schick positive state. It was interesting and surprising to find that these individuals, resistant to immunization, frequently gave a history of diphtheria in one or both parents. In one case both parents had had diphtheria. This girl was immunized but not Schick tested. She contracted diphtheria after a short service in the contagious unit. The Hirzfelds³ report a positive correlation between the Schick reaction of parents and children and their respective blood groups. It may be that this group with a deficient immune mechanism is the chief source of our present diphtheria cases. Lennox reports 3 members of one family contracting smallpox 15 months after successful vaccination.

In most instances a negative Schick test means at least 1/30 unit antitoxin per c.c. serum. The Kellogg test is used to determine immunity by testing for antitoxic content of the blood. Here again there is not a 100 per cent uniformity between the Schick and the Kellogg tests. Certain individuals with a negative Schick test will still have a Kellogg test of "not immune." At

Children's Hospital the past 2 years we have done Schick and Kellogg tests before and after transfusions on the recipients and also tested the donors. When a Schick positive child was transfused from a Schick negative donor the usual result was that the recipient became Schick negative but *not* Kellogg "immune." In one instance the *donor* was Schick negative and Kellogg "not immune" and in this case the recipient's Schick state remained positive. In other instances as little as 4 c.c. of blood given intramuscularly from a Schick negative donor neutralized the Schick test of the recipient. One of these donors was tested for antitoxin content and found to have 5 units of antitoxin per c.c. of serum. This donor had never been immunized but had had repeated Schick tests. It is possible, therefore, for two individuals both having become Schick negative without immunization to vary in the antitoxic content of their serum from less than 1/30 antitoxin unit to at least as much as 5 units per c.c. This knowledge becomes significant when human serum is used for specific therapy. In the recent epidemic of poliomyelitis, Schick and Dick tests were done on patients receiving human and animal sera. In patients receiving human serum the Schick tests were negative except in 2 instances where a faint reaction occurred, whereas several receiving sheep serum had strongly positive Schick tests. There were practically an equal number of Dick positives in the two groups.

It is quite evident from the presented facts that individuals vary greatly in their immunity to disease, but, in addition to this, any given individual's immune state is also subject to change. An infant under 5 or 6 months does not usually contract measles, scarlet fever, or diphtheria; yet he is susceptible to smallpox, chicken pox, and pertussis. The erysipelas mortality in the newborn is extremely high; after infancy

he withstands the infection well, but as he ages he again succumbs to it. In some diseases like meningitis and tuberculosis mortality among adolescents is high. In practically all epidemics of poliomyelitis the mortality has been very high in young adults. On the other hand, time and age increase the resistance to a great many infections.

In addition to constitution and age, a third factor must be considered, namely, environment. In the rest of the animal world, the law of survival of the fittest rules. Civilization has interfered with this law. Sanitation, isolation, treatment of disease, and immunization affect the natural course of life. The most radical of these interferences probably is artificial immunization. One is justified therefore in raising the question, is there an optimum time for such interference? Vaccination against smallpox is generally advised between the ages of 6 months and 1 year or shortly thereafter, because reactions are less severe and undesirable sequelae less frequent. In a group of infants immunized with toxin-antitoxin a few years ago the best results were obtained when immunization was done between 10 and 15 months of age, both those done before and those done after this age showing a higher percentage of positives.²

FIGURE I

ILLUSTRATING VARIATIONS IN IMMUNITY
DUE TO CONSTITUTIONAL DIFFERENCES
AND MATURATION CHANGES.

In order to summarize or visualize this entire problem the diagram (Figure I) was made.

CD represents constitutional variations. These are shown as blocks rather than curves, for at present we do not know what type of curve individuals arranged according to immunity would take. A and B represent age or maturation changes. It is obvious that AB are averages for all groups. Whether or not curves plotted for C and D separately would be the same is unknown. Other questions arise such as: Is immunity separate and specific for each disease, or can an individual have good immunity to diphtheria and poor toward smallpox or poliomyelitis? If a person has poor immunity as a child, may he by the maturation process change to an individual with good immunity? or does the individual retain his original type throughout life and for all infections? Can the environmental factors alter the individual's immune mechanism? may fatigue, cold, and worry, alter it unfavorably or will diet

and vitamins improve it? How much does artificial immunization change the immune state?

Our ignorance of this subject is colossal and an attempt to study it appears futile. However, if we choose to make a careful study of the exceptional cases (both those long-lived and those showing very poor immunity) as to constitution, endocrinology, heredity, longevity, blood grouping, response to various diseases, and so on, we may be able to project the rest of the curve and thus get a better conception of the entire problem.

In the meantime, this crude representation may form the scaffolding to the structure into which we can gradually place our facts until the true picture is complete.

What's a Committee?

THE ideal committee, of course, consists of three men. One must be the active chairman; one should be in Europe and the third in Timbuktu. The main idea is to keep the three far enough apart so that the chairman will be able to get the job done. There's

sense in the story about the small boy who asked his management engineer father: "Father, what's a committee?"

"A committee," answered father, "is a body that keeps minutes and wastes hours."—*Net Results*, May, 1935.

Tuberculosis Control in a Railway Health Insurance Program*

PHILIP KING BROWN, M.D., F.A.P.H.A.

Southern Pacific Hospital, San Francisco, Calif.

SINCE 1864 with the completion of the first part of the old Central Pacific Railroad, it was found necessary to provide accident and medical service to the employees of the road, because there were so few practising doctors in the state and almost no hospitals. A monthly deduction charge of \$.50 was required of all employees, and this served at that time to cover the expense of such care as the men received. The service was very largely surgical and continued so down to the time of the World War. The steady improvement in the type and extent of care given the patients, together with the better education of physicians generally, and the increased costs in methods of scientific investigation of disease, made this care of patients much more expensive, and the deduction has increased until now it is \$1.50 a month. There have been no medical conditions which were not treated in late years, in contrast to earlier years when exemptions were made where patients were found to be suffering from certain chronic conditions.

The present Chief Surgeon takes the very liberal and just ground that people have to work and that, since as high as 31 per cent were found to have correctable defects in the draft group, it was desirable that somebody should correct

these conditions before they make serious trouble, rather than take exemptions and have labor try constantly to "put it over" later in any way it could, under claim of industrial accident or disease. In the Company Hospital therefore, conditions are corrected as found. If the defects in an applicant are incapacitating they would prevent the man being employed at all, and there are certain things that have to remain entirely uncorrected like color blindness and deafness, for example. These men are not allowed to work where their defects would be a handicap.

For 22 years Wassermanns have been done on every patient admitted to the hospital, and under the present administration if lues is found it is treated. This is the most significant finding that results from routine examination because the percentage of employees who enter the hospital with positive Wassermanns has increased in 22 years from 3.2 per cent to 6 per cent. Next in importance, as a finding from routine examination, is tuberculosis, for in about half of the cases in which it is found it existed as an unrecognized incident, or if active, its true significance had not been appreciated.

The general examination on entrance to the Southern Pacific Hospital has been the means of uncovering a great deal of unrecognized disease, and has given us some very valuable means of prolonging life and usefulness, as well

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 5, 1934.

There were 27,730 hospital admissions in 6½ years.

There were 868 tuberculosis entries, including reentries for recheck.

General incidence in hospital admissions 2.7.

There were 746 original entries in which diagnosis of tuberculosis was made
Average number of employees during period 45,268
Incidence of tuberculosis discovered among employees 1.62.

as uncovering certain facts of great medical interest. For example, the history will frequently show that a man has worked 10 years in quartz mines before coming into our employ, and then will follow 10 to 20 years of employment for the Southern Pacific Railroad without any breaking down of the lung from an original silicosis. It has given us something to ponder about in regard to diagnosis. In one case a miner of hard coal for 17 years, working underground all this time, was employed, without examination, to blast rock. Within 2 years of employment he entered the hospital with a far advanced pneumoconiosis and extreme fibrosis, with a cavity in one lung and a rapid heart, but without fever. No tubercle bacilli were found in his sputum. As cavity formation has been reported in uncomplicated pneumoconiosis, it was impossible to send a case of this kind to a tuberculosis sanatorium since it would probably lead to a definite liability on our part should he develop later tuberculosis, which is not impossible. Reference is made to this case because of the serious liability which might result if a careful history and thorough examination did not make the condition entirely clear.

We have never been unfortunate enough to have to submit any lung tuberculosis case to the Industrial Accident Commission, although one stenographer who was in the habit of closing a drawer with her knee developed a bone tuberculosis at the point of contact. Her history showed that she had had lung tuberculosis which had been thoroughly arrested before entering our service, and that it did not become active at the time the bone condition developed.

There are on record in California a number of very ridiculous instances in which referees of the Industrial Accident Commission awarded compensation for the acquiring of tuberculosis. One of the worst examples is the case of a

county hospital ambulance driver who had to wash his ambulance and occasionally conveyed a tuberculosis case in it. Just how he acquired the disease from his occupation as driver and washer is a little difficult to figure out.

I have divided the admissions to the Southern Pacific Hospital into 13 groups in an attempt to have each group represent about the same type of work. Table I gives a summary of the findings.

In the first place the incidence of the disease between ages 20 and 35, and 35 and 50, is almost the same—293 and 292, while in people of 50 years of age and over, it was found in 155. It is impossible to give exact numbers in each group, but the ratio is about 4:4:2. With increasing age men come in for more and more serious things, while in the younger group such conditions as tonsillitis, or removal of tonsils, sinusitis, and trivial accidents bring the number up to a point that makes it surprising that the incidence of tuberculosis is so low. It is certainly not that the condition is overlooked at the time they are employed, because the younger they are the more attention is paid to the history and physical condition when they are examined. It is unfortunate that emergencies have to be met occasionally by taking on 300 or 400 laborers, in which event no examination can be made. A washout, perhaps, demands such immediate attention that extra men are recruited at very short notice. With the large number of foreigners that sometimes have to be employed, it has been very obvious that these people are in some cases hoping to take advantage of the industrial benefits, and we have found such a group present a large number of complaints in a comparatively short time. It would be in the interest of industry if immigrants could be examined adequately when they enter this country. In all probability working conditions are better here than they are in the places from which they come, and

when an immigrant reaches adult life with negative X-ray findings, which could be obtained at port of entry for less than \$1 each, it is presumable that he is not apt to develop tuberculosis in later life under the improved living conditions. The vast majority of our foreign employees with tuberculosis can be shown presumably to have had the disease, or the initial infection before they entered this country. The significance of our proximity to Mexico is interesting in connection with this latter problem. The number of Mexicans in San Francisco, for example, is only a few thousand, whereas in Los Angeles the number has reached as high as 300,000. The State of New Mexico had till recently more Mexicans and their descendants than all other nationalities combined. Our Negro population in San Francisco, although growing rapidly, is under 6,000, while Los Angeles has more than 10 times this number.

The incidence of tuberculosis among 27,730 admissions, not counting the re-entrances, amounts to 746 or 2.7 per cent. When the total number employed is considered and not the hospital admissions, the incidence is 1.62 per cent. There were 142 readmissions of these cases, chiefly patients who had returned from the sanatorium at Tucson to this neighborhood and were reexamined as to fitness to return to work. It has been our policy, if they are not in a very thoroughly arrested state within the year that we give them care, to try to provide for them through the county tuberculosis hospitals in their home districts if they have no homes of their own.

It is a very significant fact that the incidence of tuberculosis is highest among the groups that are not examined before they are employed. We have been particularly struck with the fact that out of a group of 14 interns taken annually there is apt to be 1 who is found to be actively tuberculous and 2

or 3 whose childhood infection is suspiciously severe and threatening, and who during the year's work with us develop conditions that make it necessary to take chest plates and temperature records and deal with potentially incipient conditions. One has to ask himself if the number of interns who apply from eastern colleges may not wish to come to California on account of some known or suspicious condition, and whether it would not be wise to ask them to send X-rays of their chests rather than their photographs and certificates of good moral character. Nurses who are not examined have a fairly high incidence of the disease although they are not exposed to tuberculosis, especially in the hospital since we send our lung cases to Arizona as fast as they are diagnosed.

A rather surprising fact is the protection that good pay and intelligence are to men who are undoubtedly exposed to considerable dust when riding in either closed cars or on engines, or getting off at stations in all sorts of weather. A group of train and engineers, of whom there were 8,087, showed an incidence of 0.84 per cent. Only 3 of the 68 cases had far enough advanced tuberculosis to die from it eventually, although nearly 25 per cent had cavities when first examined. They represent the highest paid group of all employees except executives. In contrast to these men, the executives, officers, and assistants show an incidence of 3.14 per cent, while their clerks and stenographers and other office employees exposed possibly to less favorable office conditions, show an incidence of 1.76 per cent in a group of 7,382. Another entire group in the shops, stores, and commissary department, numbering 12,286, show an incidence of 1.18 per cent, while 10,598 outdoor workers in maintenance of way and bridge building show 1.5 per cent. In cooks, waiters, and porters, of whom there were over 1,000, all Negroes, the

incidence was 4 per cent. This is probably due to the fact that they are examined annually and an X-ray plate made of the chest of every one. The fact has been brought to light with sufficient emphasis to make it important that family contact with tuberculosis is responsible for the disease in a very high percentage of these cases. Part of the history taken in such cases should be the occurrence of any questionable condition in the family and the making of such a condition reportable to the company. It would be difficult to enforce this, but the wives of a number of our colored employees have been found, through the local social service departments, to have the disease. This fact has been uncovered in seeking to provide for our employees' families through social agencies while they are being cared for at the tuberculosis sanatorium, or when the home is investigated because of our desire to send a patient back for further care in his home after his year under our sanatorium service.

Dufault and Robinson¹ review the subject of tuberculosis among the members of the same family and also the literature, the curious fact being brought out by Turban, quoted by Baldwin in 1902, that 80 per cent of 55 families showed evidence that the disease originated in the corresponding lung of the consort of a patient with lung tuberculosis. In Baldwin's 65 families 166 individuals (70 per cent) had developed tuberculosis in the corresponding lung. In 28 with parental tuberculosis 78 per cent had children with homolateral disease. In 35 families with one or more tuberculous brothers 63 per cent had the disease homolaterally. Fishberg has observed the same condition in two-thirds of the cases in which several members of the family were affected. The danger of housing open cases in families where there are children has been appreciated for decades. In California, state aid for the minor children

is refused if the breadwinner with open tuberculosis remains at home.

Just how far it is the duty of industry to insist upon the examination of doubtful family cases is a question, but in the Southern Pacific Hospital we have extended the services of our own laboratory to test the blood for lues in the members of the family of every instance where our employee is known to have the disease. It is a piece of public health work that promises much for a proper system of health insurance made compulsory for low wage earners. We try to have local doctors or clinics examine the families, and we know that if state aid is applied for, the local welfare director will see to the examination of contacts.

Conjugal tuberculosis is a far more important matter than is appreciated and although the extent of it is still under discussion it is growingly shown that it must be considered seriously.

S. Tillisch from the Grepén² Sanatorium, Norway, shows that in 1,152 married patients 85, or 7.4 per cent, the consort had pulmonary tuberculosis. Among 841 patients with active tuberculosis her husband found 18.5 per cent had clinically demonstrable evidence of childhood tuberculosis. Harbitz concurs in this frequency. In 72 of her 85 cases there was no clinically demonstrable evidence of childhood infection, making the percentage 6.2, in which the consort of a tuberculous individual acquired the disease from this source.

S. Rowland,³ Tuberculosis Officer for Northampton, England, quotes E. Ward as showing of 156 cases (120 wives, and 36 husbands) 91, or 58 per cent, showed the consort to have tuberculosis, but considers the death rate of consorts more reliable. His figures show 1,242 certified tuberculous causes of death 1911-1920, of whom 525 were married, with only 15 instances where both partners were certified as having died of tuberculosis and one of these was

doubtful. Two and seven-tenths per cent represents his figures on accepted cases, while the general death rate from tuberculosis was 1.1 per cent in England and Wales.

The obvious criticism of these figures is that they should have included the deaths from tuberculosis in the 5 to 10 years preceding and subsequent to his elected 10 years of any conjugal connections of people dying of tuberculosis in that period, or it should have included the conjugal deaths in a longer period, so that the overlaps in the period before or after the 10 years selected, would represent a smaller percentage of the total possibility. Rowland's method does not admit of a long enough lapse in time between the deaths of husband and wife. With better methods of diagnosis the clinical determination of tuberculosis should be sufficiently dependable to cover the facts of the case.

M. Fishberg^{4, 5} states that he has never observed a case of lung tuberculosis transferred from one consort to another. He made an extensive study later, and reports examining 9 women consumptives and 161 men. In 3 per cent only were husband and wife tuberculous.

Weber⁶ reported 147 cases of tuberculosis acquired by consorts of 68 consumptives. This was before the discovery of the tubercle bacillus, and the method of contagion was not known. Nine tuberculous husbands lost 18 wives with the disease, 1 lost 4, 1 lost 3, 4 lost 2 and 3 lost 1 each. In the *British Medical Journal* (about 1888) is a report of 18 consumptive widowers of whom 11 per cent lost wives with consumption, and of 29 consumptive widows of whom 17 per cent lost husbands by the disease.

Brehmer, in 159 couples one of whom had tuberculosis, found 12 per cent of the consorts infected. Jacob and Pannwitz, in tuberculosis sanatoria in Germany, found 8.57 per cent of cases where tuberculosis existed in both of

married couples. Weinberg⁷ reports 8.3 per cent of husbands of tuberculous wives died from tuberculosis, whereas only 4.5 per cent of wives of tuberculous husbands died from it.

Minnig, before his study at the Denver Municipal Clinic, was prejudiced in favor of Fishberg's idea of the non-existence of conjugal tuberculosis but after a study of 1,000 cases he made the statement that an average of 8.7 per cent showed the disease in both partners, and added: "If we take the normal incidence to be 2.7 per cent among all classes we do not find anywhere in the literature so low a percentage in the consort of the infected husband or wife."

Crouch, of the Modern Woodman's Sanatorium at Colorado Springs, showed even more strikingly that the wives of tuberculous husbands acquired or died from the disease to the number of 6.4 per cent, while 58 per cent of widowers who had lost wives of the disease, acquired it.

An extraordinary variation continued throughout a long list of observations here and abroad. This brief review of the situation is given for the sake of bringing out the point that the great variation in opinion among investigators does require a certain standardization, if one would make comparisons, but the fact cannot be evaded that, while there exists a protective relative immunity in cases where mild exposure occurred in youth, the frequency of this immunity being overcome in the case of adult exposure must be recognized.

The frequency of tuberculosis in nurses has been called to attention many times. Shipman, University of California, has dwelt on it a number of times. Geer in Minnesota has written twice on the subject recently, and in his article in the *Archives of Internal Medicine*,⁸ January, 1932, shows that 5.5 per cent of 110 nurses who entered training were tuberculous within 2 years. He contrasts this with Ship-

man's 2.6 per cent in the University of California training school over a period of 6 years. Much, in the Eppendorf Hospital, found his percentage reaching from 1 per cent to 4.6 per cent after the war. Ross, in 800 cases in Manitoba, found 6 per cent had developed tuberculosis in a 4 year period. The average incidence in women of the same age is estimated at 1.5 per cent. Geer has also reported twice on the incidence of tuberculosis in the Aucker Hospital in St. Paul. His latest figures show an incidence of 4.5 per cent of tuberculous disease among nurses in the training school. In September 1928, he undertook to test all nursing school applicants with tuberculin and those that were negative were retested every 6 months—30 per cent were reactors on entering the training school, and nearly 100 per cent before the training was complete. In 5 other St. Paul hospitals the average percentage of reactors was 42 in the 3rd year of training, and no cases of tuberculous disease in the 2nd year period prior to this were discovered. Geer makes the important suggestions that all nurses employed in the hospitals, and all student nurses be given a tuberculin test and have a chest plate made. He recommends better supervision of the hygiene of all tuberculous patients that are admitted.

The hospital should be a school and far more attention should be paid to teaching patients, through both nurses and doctors, as to how to handle their infirmities. A great deal of attention is given to those phases of our responsibility in the Southern Pacific Hospital. Cases of a single classification are kept together so that patients may learn also from each other. As it is frequently necessary to keep lung cases for some weeks before they are sent to Arizona, it has become a custom to use this period for instruction, not only of the patients but also of the nurses who have the care of them.

The high incidence of the disease in crossing flag men and bridge watchmen of 5.1 per cent is due to the fact that these men are frequently employed when long past 45 years of age, and without examination. It represents also one of the mistakes in excluding any class from a thorough physical examination on employment.

The 42 cases diagnosed as having tuberculosis of the lungs in the General Hospital from among yard foremen and yardmen, hostlers, ice foremen, and icemen, represented 11 per cent of the total employed in those fields, the highest incidence of tuberculosis by far, and demanding an explanation. Accordingly those 42 histories were reviewed in detail, with the following facts brought to light. Most of the cases were from the Southwest. Only 4 were icemen and 2 of these were foremen with 10 and 25 years service. Neither was admitted for lung condition. One had an arrested or apparently cured condition, and the one employed 25 years had a definitely active process. The 2 icemen had been employed respectively 1 and 5 months. They both had had pleurisy before employment, and the one employed 5 months had a healed lesion of one apex. The other came in to have an old hernia operated on. It could not be determined that the occupation had anything to do in either of these cases with the pulmonary condition.

In taking over another railroad in the Southwest it was found that of approximately 40 to 50 clerks sent to San Francisco 20 per cent had had tuberculosis and were sent back to the Southwest to the climate and surroundings they had been used to. This is cited as further evidence of the frequency of arrested pulmonary tuberculosis in that region.

Among the 38 men who worked on or about the motor equipment at station yards, 9 were apparently healed old lesions, 18 were in an active stage and

recent, and 11 were chronic cases. Of the 18 acute cases, one was admitted with tuberculosis of lungs, kidney and bladder, 5 had productive cough, 2 were supposed to have influenza, 3 had had accidents, 1 a hernia, 5 complained of such things as neuralgia, sore throat, and run down state, and 1 was short of breath. It must be remembered that if there is anything not obvious about an employee's condition he is sent into the General Hospital. X-rays and sputum examinations in small towns are sometimes difficult to get. The Hospital rule to examine every man from head to foot, no matter what brings him into the Hospital, uncovers fully half of the tuberculosis cases, and it is quite noticeable that among employees in Southern California, Arizona, New Mexico, and Texas, we have many cases of healed tuberculosis besides the incident of silicosis without tuberculosis.

In connection with silicosis it is important to call attention to dust as a hazard in railroad work. Russell⁹ reports the investigation of:

The cement industry, representing calcium dust.

Silver polishing, representing metal dust.

The granite industry, representing silica dust.

The coal industry, representing carbon dust.

The cotton industry, representing vegetable dust.

Street sweeping, representing municipal dust.

The conclusion is drawn that silica alone is a matter of importance. In various industries where grinding is done this matter is borne out by extensive studies, but apparently it is the silica and not the metal dust that makes the trouble. A case is shown however, of a World War veteran with a process that looked so like miliary tuberculosis that it had to be studied with great care. The boy had been employed sweeping out plaster molding works, and it was only after we sent to Portland, Ore., to have his brother's chest X-rayed and found that he had precisely the same picture though to a

somewhat less extent, as he had not been so much exposed to the dust of the plaster works, that a presumptive diagnosis was possible.

SUMMARY AND CONCLUSIONS

1. The important point in this study is that no matter what people enter a hospital for, the chance for a complete examination is too important a matter to be overlooked, and in advising people about themselves all the facts that have entered into their health problems should be known.

2. Arrested cases of tuberculosis in industry present an economic problem that is very important and only the most intelligent of the arrested cases can be trusted to protect themselves by what they have learned while getting well.

3. The racial differences are shown in the incidence of the disease among Negroes.

4. The problem of tuberculosis in the Pacific Southwest was illustrated by the fact that when the Southern Pacific Railroad bought a rival road running through its territory 11 of the officials who had been transferred to San Francisco had to be provided for in their former environment because of conditions of their lungs which had brought them to the Southwest.

5. Finally, annual examinations in industry are of the utmost importance from an economic point of view for industry and employees.

An Automatic Liquid Dispenser

HENRY BUKOSKI

Michigan Department of Health, Lansing, Mich.

THE fact that accurate dispensing of large volumes of media in small amounts is a tedious and time consuming operation resulted in the designing of the dispensing apparatus shown in the drawing.

The dispenser is made from glass tubing and the siphoning action is self-explanatory. The volume of liquid that empties at one time depends on the height C, the width D, the diameter of the S-tube, and also on the frequency of emptying. The frequency of emptying is controlled by the constricted tube B which must fit loosely into the S-tube. A pipette tip serves well for this purpose. The frequency of emptying may be further controlled by a Hoffman clamp. The dispensing is intermittent; and the operator is able to manipulate a rack of tubes, moving the rack over to locate an empty tube under the dispensing arm while the S-tube is filling. Pinch cook A is used when it is desired to stop the dispensing, otherwise flow through B is continuous.

The apparatus can be used for dispensing serum or melted agar media as well as broth. We have also used it successfully in dispensing Loeffler's

medium, and for filling silver nitrate solution into wax ampules for prevention of ophthalmia neonatorum.

FIGURE I—Dispenser Apparatus

With a small amount of practice one will be able to more than double one's output using the old pinch cock method.

TABLE I
DIMENSIONS OF SOME DISPENSERS

<i>Inside Diameter of Tube</i>	<i>C</i>	<i>D</i>	<i>Volume of Each Discharge</i>
5.5 mm.	6.0 cm.	9.0 cm.	4.16 c.c.
5.5 mm.	8.6 cm.	9.3 cm.	5.8 c.c.
7.0 mm.	8.9 cm.	8.1 cm.	7.5 c.c.
5.5 mm.	16.6 cm.	11.2 cm.	10.2 c.c.
10.0 mm.	13.0 cm.	13.0 cm.	24.5 c.c.
3.5 mm.	1.6 cm.	1.4 cm.	0.4 c.c.

One hundred Loeffler's tubes were filled by each of the two methods in a test run. The time required when using the automatic dispenser was 3 minutes 16 seconds. When using the pinch cock method, 8 minutes 31 seconds were required. Another advantage in the use of the dispenser is the large saving in media, due to the fact that only the right amount of medium, and no more is dispensed into each tube or flask.

Table II shows the weights in grams of 16 consecutive discharges of water from one dispensing apparatus at the rate of one discharge per 2.6 seconds.

A modification of this apparatus has

been designed for dispensing sterile solutions and will be reported on at a later date.

Chicago Study of Premature Births

THE Health Department of Chicago, Ill., made a study of the death certificates of infants born and dying in hospitals having more than 200 births a year, which shows that the death rate of premature infants under 15 days of age was as low as 5 per 1,000 births in

some institutions and as high as 50 per cent in others.

The Department of Health has established a 24 hour incubator ambulance service for hospitals without incubator facilities and for private physicians delivering mothers in the home.

I GIVE AND BEQUEATH

THROUGHOUT the 64 years of the life of the American Public Health Association a Big Problem has existed. It exists today. It is set in capital letters and even in bold face in everyone's thinking. The Big Problem has faced every officer who ever served in any capacity in the Association. It has absorbed years of time of the governing bodies and eons of time of staff members. No one can say what discussions revolved around it in the earliest days of the Association's being, but it was probably then, as it is now, the *bête noir* of every Executive Board meeting.

The Big Problem is finance.

When the Association was organized in 1872, the membership dues were set at \$5.00 a year. They have never been increased. The grade of Fellowship was created in 1922 with annual dues of \$10.00, but the classification may be ignored in this discussion because it involves less than 20 per cent of the membership. Though dues remain at \$5.00 for the majority, services to members have greatly increased. The membership is not unaware of the fact that the total income from all classes of membership dues is only 25 per cent of the Association's budget. It is common knowledge, too, that the remaining 75 per cent is secured from grants and from the organization's business services and not through or from the membership.

The Big Problem reappears constantly because of the uncertainty attending gifts and because of fluctuations in general business which the Association's commercial activities faithfully and dishearteningly reflect.

Such a hand-to-mouth existence invites emergencies. After each has been weathered (do not ask us how) the necessity for a stable financial structure becomes more apparent.

An endowment fund that some day will yield sufficient income to cover the basic and essential expenses is the heritage those currently serving on the Executive

Board would like to leave their successors. By basic and essential expenses is meant the costs of maintaining an office, of supplying a magazine, certain other publications, and an Annual Meeting to members. It is generally recognized that an endowment fund for the A.P.H.A. probably never will be achieved through one or several large contributions. Instead, a slow building up process is indicated during which hundreds and even thousands of small gifts will be accumulated over a period of years.

We hasten to say at this point that our present purpose is not to ask readers to add from their small earnings to an endowment fund. If the urge to do so becomes intolerable, however, permit us to intimate that checks made payable to the American Public Health Association will be deposited in the proper account. Our chief intent is to give some background of the Association's financial difficulties, comment on the Big Problem, and point out its ultimate solution.

In preparation for the last mentioned, it should be noted that no one, in all the years of the Association's useful life, has ever made a bequest in its favor. This seems odd in retrospect because in past years there must have been fortunate citizens connected with and interested in the society who were in a position to will it something. Indeed, we have evidence that there were, in the reality of substantial cash contributions made by several individuals in days gone by. We have no way of knowing whether the Association figures in the wills of those of the donors who are still living. We do know that not one who has died remembered the society in his will.

It is not too much to hope that the A.P.H.A. may benefit by legacies in the future. After all, we are a body of professional people, the vast majority of us with jobs which have never paid us princely sums but which, on the other hand, have been sure, and have paid us greater or lesser salaries over a period of many years. Most of us own our homes, educate our children, eat and sleep somewhere ourselves with a fair degree of regularity and have a liberty bond or two tucked away against that inevitable day of retirement. There are without doubt a few among us blessed with a sense of acquisitiveness, or a flair for the sound investment, or fortunate enough to have been born with a silver spoon in our mouths, or to have had advantage of any of the thousand odd tricks of fate that result in making a few better off than others. These fortunate ones could even now provide a small legacy for the Association. That group also undoubtedly has well-to-do friends. Sometimes it is easier to persuade someone else to do something than to do it one's self. They could recommend the mention of the A.P.H.A. in a number of wills. Further, the poorest of us, our positions being what they are, know officially and very often socially people with much larger incomes than our own. Here again the worthy cause the A.P.H.A. represents can be dwelt upon as something to be considered in the ultimate disposal of worldly goods.

If we cannot give and bequeath, therefore, it may be entirely possible for ours to be the influence that induces someone else to do it, and the glory and credit in either situation is the same.

The solution to the Big Problem is not an out-and-out donation running into many figures which will provide insurance to time eternal against worry and the constant search for pay-dirt which goes on continuously in the Executive Board and in the headquarters office, but an endowment fund arrived at after a number of years through a slow process of education and persuasion. The secret of the strength of the Association lies in its struggle to overcome financial obstacles. Too much money too easily arrived at is the cause of "Nervous Prosperity," as one

old-time physician diagnosed a case, quite as surely in organizations as in individuals. No one wants to see the Association sitting in the lap of luxury with the enervating, devitalizing hazards that such a situation brings. A margin of financial safety broader than the Association enjoys now, however, is a consummation devoutly to be desired. In anticipation of that, let us scan our friends' and associates' resources, and our own as well, with a view to disposal of a small portion of them eventually to that end.

A hint to those who have it in their power to help—It is much easier to get money for a project than a program. The *American Journal of Public Health* is a project well worth supporting. It lacks the dramatic appeal that a wheel-chair for a crippled child, for example, possesses. It must be sold to the intelligence and not to the emotions, and that is the hardest kind of selling. However, someone might consider its 25th birthday, occurring this year, worth commemorating through a contribution to be spent on paper and printer's ink.

"I give and bequeath" are words that extend an individual's influence and personality beyond the moment when he shuffles off this mortal coil. They are capable of assuring a measure of immortality to the writer if they are wisely directed. Let us hope they may be written many times in favor of the A.P.H.A.

INTERNATIONAL BIOLOGICAL STANDARDS

IN 1926 the Health Committee of the League of Nations appointed a permanent commission for the study of international standards for biological preparations under the chairmanship of Dr. Th. Madsen, Director of the State Serum Institute of Denmark, Copenhagen. The work has been apportioned to well known institutions in various countries—Germany, Denmark, the United States, France, and Great Britain having taken part. In most cases the laboratories coöperating were national institutions. Conferences have been held, discussions carried on, and results compared. There are now 22 international standards, including 9 for antisera, old tuberculin, insulin, pituitary extract (posterior lobe), estrous hormones, 3 of the arsphenamine group, 4 vitamins, ouabain and digitalis.¹

The most recent information which has reached us² tells of the adoption of international standards for gas gangrene antitoxin (*vibrio septique*), gas gangrene antitoxin (*edematiens*), antipneumococcus serum, type I, antipneumococcus serum, type II, and staphylococcus antitoxin. The Commission has asked the State Serum Institute of Denmark to draw up a scheme for the determination of an international standard for antitetanus serum, so that we may confidently look for a standard for this product in the comparatively near future. The status of antidysentery serum, Shiga, is also somewhat unsettled and the Commission has asked that the documentary material on hand should be reëxamined. The question of antityphoid serum has been placed on the agenda of the next session of the Commission.

One of the controversial matters is streptococcus antitoxin. The American standard adopted by the federal government has been selected as a basis for study and the Hygienic Laboratory (National Institute of Health) has agreed to place at the disposal of the Health Organization of the League of Nations a sufficient quantity of the standard serum for study. Up to the time of this report no effective action has been taken toward the adoption of an international standard for this serum, action having been hindered by the patents granted in the United States and several other countries covering the production and testing of the

product. Even in countries such as the United States, where a legal standard serum and unit in terms thereof have been defined officially, the manufacturers are obliged to submit samples of each batch of serum to the patentees for an independent and possibly discordant indication of its value, in units defined by them. Under the circumstances the Commission decided it was useless to proceed with work looking to an agreement on a standard and unit for international work which might conflict with the authority exercised by the patentees. This decision and the reasons for it were reported to the Health Committee of the League of Nations.

Up to 1914 the most important standard was that for diphtheria antitoxin which was established by Ehrlich and kept at Frankfurt, Germany. After testing in several countries, the original unit was accepted for the international standard.

The Health Organization of the League of Nations has placed the responsibility for the care, storage, and distribution of the standards adopted upon the State Serum Institute of Denmark and the National Institute of Medical Research at Hampstead, England. The former is responsible for all the serum standards and that for old tuberculin, while the latter has charge of those for hormones, the vitamins, digitalis and ouabain. In general these two Institutes distribute the standards to national central laboratories selected by the League and from them are distributed to smaller laboratories and research workers. Where there is no national central institute the standards are supplied directly from Copenhagen or Hampstead.

The work has progressed most satisfactorily. It is under the most competent direction that the world affords so that one may have great confidence in the products issued by any laboratory under national control in any of the countries adhering to the League. For the United States the standards are distributed by the National Institute of Health of the Public Health Service, Washington, D. C.

SIR GEORGE NEWMAN

NEWS comes to us from England¹ that Sir George Newman retired March 31, 1935, from the offices of Chief Medical Officer of both the Ministry of Health and of the Board of Education. In England, according to the testimony of *Public Health*, this will bring to an end an era in which the developments which have occurred in the field of public health are described as momentous. The influence of Sir George Newman on these developments has been enormous. It is only by and through him that the health machine, including as it does the school health service, the maternity and child welfare scheme, and the extensive general public health service, has moved so efficiently and smoothly. Indeed there is just reason to believe that but for him this machine would never have existed and would never have been perfected. His knowledge and ability as well as his organizing capacity were required and brought into action.

Since 1907 Sir George had served as Chief Medical Officer of the Board of Education. It will be remembered that the need shown by the great war led to the creation of a Ministry of Health and he was appointed Chief Medical Officer of that service. He made the position of Chief Medical Officer and filled it adequately in every way.

In America we know him not only as a master executive officer, but as the writer of essays which have had a far reaching influence. His annual report was a textbook and guide to us in this country, not only recounting the aims and accomplishments of the Ministry of Health of England during the year, but discussing in a masterly way many matters of general interest. England will miss him more keenly than we in this country can, but none the less, his retirement is a matter of great concern to us.

His successor is Dr. Arthur Salusbury MacNalty. The Deputy to the Chief Medical Officer is Dr. Thomas Carnwath. Both of these officers possess high capabilities, and with our congratulations we wish for them successful tenure of office.

MORE PUBLIC HEALTH AWARDS

IN the May *Journal* the winners for 1934 of the Health Conservation Contests, conducted by the Chamber of Commerce of the United States at Washington and the American Public Health Association, were announced.

Two additional special awards were offered, one for cities and the other for counties, in the form of free public health surveys. Announcement has just been made that for 1934 the award for cities goes to Louisville, Ky., and for counties to Spokane County, Wash. These awards are open to all participants in the Contests except the winning cities and counties. The awards are made on the basis of the claims presented indicating the need of such a survey, the readiness of the community to coöperate in the survey, and the assurance that serious efforts will be made to carry out reasonable suggestions for improvement. The Grading Committee had a difficult task in deciding the winners as 27 communities presented strong claims for this special award.

PUBLIC HEALTH EDUCATION *

Please Check Your Mailing Lists

—You who are sending house organs, news releases, radio talks, and other routine material for possible use in this department of the *Journal*: please *check your mailing lists* to see that your material actually is sent.

Mailing lists are perverse, and subject to unexplained and unanticipated changes and errors.

We have had assurances that material was being sent which never arrived, or which came for a time, and then never more.

Unless your mailing list carries the name of Evart G. Routzahn we do not hear from you. Then the address should be: 130 East 22d St., New York, N. Y.

A Coöperative County Program

—*Michigan Public Health*, Lansing (March, 1935), tells what a little organization plus some energy accomplished in one county.

As a result of the combined efforts of the Health Education Committee of the Washtenaw County Medical Society, the County Commissioner of Schools, the County Nurse, the Extension Division of the University of Michigan and a member of the Health Committee of the County Federation of Women's Clubs, 38 speakers gave 105 lectures in 93 rural communities to audiences totalling approximately 4,500.

Planning of the program was done by a committee made up of representatives of the interested organizations. The organization of the lecture schedule was carried on through the medium of personal visits to the 130 rural schools in the county. These visits were made by the County School Commissioner, or a member of the Health Education Committee

of the County Medical Society, or the Chairman of the Health Committee of the County Federation. The program was explained and offer of the lecture service was made to the local teacher and the members of the school board. If participation in the program was desired by the local school officials, formal request was made by them to the Chairman of the County Medical Society Committee, who, in turn, arranged the assignment of speakers.

A total of 38 lecturers participated in giving the talks. Most of them were physicians, one was a dentist, and the others were specialists in some phase of public health from the staff of the University of Michigan. They lived in Ann Arbor, Ypsilanti, Milan, Clinton and Dexter. In the assignment of speakers, effort was made to have the men talk in their own districts, and if possible on their own specialties.

One hundred and five lectures were given during the program, all of them to adult audiences and most of them in rural schools although some were given in connection with Grange Meetings, Farmers' Clubs, Parent-Teacher Associations and similar groups. In all, 93 schools participated, and the average attendance at the meetings reached the unusually high mark of 50.

A Doctor's "Plain Language"

Reported by Associated Press from Kansas City:

Transcript of proceedings in a damage suit today:

Lawyer—"Doctor, in popular language, please tell the jury the cause of the patient's death."

Doctor—"In plain language, he died of an oedema of the brain that followed a cerebral thrombosis or possibly embolism that followed. In turn, arteriosclerosis combined with the effects of gangrenous cystitis. . . ."

The Forbidden Topic—Dr. John L. Rice, speaking in New York City, said:

Two or three months ago, I was invited to speak before a Kiwanis Club in New York on what the taxpayers in that group get for their

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

money in the way of public health from the New York City Health Department. The talk was also being broadcast to the public.

I began by telling of the activities of the various bureaus. I think at the end of about the first 5 minutes I came to the matter of communicable diseases, which was followed with the venereal disease work. I no sooner referred to "venereal diseases" when I heard a commotion in the corner of the room; the kindly chairman had been whispered to and said, "You can't talk about venereal diseases." I hesitated for a moment and then went on, omitting further reference to venereal disease.

A friend of mine, who is the president of the Connecticut State Medical Society, wrote me a letter the following day, expressing his appreciation of the talk and his regret that I had been cut off from talking about venereal diseases on the radio. It seems to me that the proper use of the radio is one of the steps in the advancement of public health education upon this important group of communicable diseases.

A few nights ago, I was coming in from Queens and I had as driver of the car a man of 30 or 35, a pretty intelligent sort of person. On the way back, he asked, "Is it true that physicians cannot ethically treat cases of venereal diseases? Is there something in the state medical regulations which prohibits the ethical doctor from doing this or giving treatments for venereal diseases?"

Those are two experiences which make me think we still have a long way to go in getting this information over to the public.

Health Education at Saranac—On June 21-22, 1935, preceding the National Tuberculosis Assn. convention, a "post-graduate study on health education" will be held at Saranac Lake, N. Y. Sponsored by Conference of Tuberculosis Secretaries; subject, "Putting our knowledge to work"; sessions on "What are we trying to do?" (program for combating tuberculosis); "What shall be taught?" (content); "How shall we teach?" (method).

"Can You Smell the Elephant?"—This is the title of an 8 page folder issued by Michigan Tuberculosis Association, 535 S. Capitol Ave., Lansing.

Johnnie, who had recently been to a circus, went to visit the school where his sister teaches. That day they were presenting for entertainment, a mock menagerie. As Johnnie walked in the door, he said to his mother, "Ooh, hurry, they've started! I can smell the elephant."

Of course, there really wasn't an elephant, but you couldn't blame Johnnie for thinking so, his sister decided after she walked outside and in again. The air in the schoolroom didn't at all make one think of the outdoors.

So she decided to do something. She appointed a committee of pupils to help.

Every day at 10:00 and 11:30 in the morning, at noon, and at 1:30 and 3:00 in the afternoon, the committee walked outside and back into the room. When they came in, they:

*Tried to Smell the Elephant,
Recorded the Temperature,
Looked at the Waterpan*

Then follows an account of home-made devices by which that school controlled heat, air, and moisture. Every step is illustrated by line cuts.

Health Education in Tennessee—The recently issued report for 1931-1933 of Tennessee Department of Public Health includes 10 pages on health education, and 4 full-page illustrations.

Public health education activities are necessarily a definite part of every activity of a public health program. Public health education is the foundation of all public health work. It is the fundamental principle guiding the whole program. Through the local full-time units more health education is extended to the people on account of trained public health workers making day-by-day contact with individuals than in any other way. Quite naturally this scheme of educating the people is of prime importance.

The Department has engaged in public health education in all the work, but more directly through the activities (which are presented in some detail).

School Health Program—The report says:

The school is the strategic place in which to establish a health education program. If it is carried on systematically, it reaches the entire population during the impressionable learning period, when habits and attitudes are being formed. The child's health pro-

gram functions 24 hours a day, and unless a positive, constructive program is encouraged, wrong habits, attitudes, and information are sure to be acquired.

Five pages are given to this subject, with particular attention to the Blue Ribbon Program in the schools. Elementary pupils who meet the blue ribbon requirements receive a small bar pin mounted on blue ribbon.

The requirements for the blue ribbon include average scholarship, behavior and health habits; the correction of remediable defects, and immunization against typhoid fever, diphtheria, and smallpox. The teacher determines the pupil's fitness for the ribbon in scholarship, behavior, and health habits.

The practice of sound health habits year after year will help to develop a sane attitude toward health as a normal quality of living rather than a subject to be taught. The habits stressed are those of adequate sleep, fresh air, exercise, cleanliness (internal and external), and the eating of protective and building foods. Nutrition is stressed because it is one of the serious problems of the child in the rural community.

The correction of defects has been made possible by the enthusiastic support of the elementary teachers, school principals, and county superintendents, and the intelligent coöperation of such individuals and groups as the local physicians, dentists, and specialists, the parent-teacher associations, women's clubs, Legion, auxiliaries, community clubs, Legion posts, men's luncheon and civic clubs, church organizations, local press and others. In some communities, clinics for correction of defects are held annually and are carried on by the pooling of all available community resources of supplies and personnel.

In a number of counties the Blue Ribbon Program culminates in a county-wide observance of Blue Ribbon or Child Health Day. The children who have qualified take part in a short parade, pageant, field day, or have some other form of recognition. Sometimes they are guests at a moving picture or meet at some public building for the awarding of school prizes. No prizes are given to individual children and the awards to schools are based on the number of blue ribbons in proportion to average daily attendance. Anybody who has seen these hundreds of children from the elementary schools, massed under their school banners, with bands and flags adding to this picture of life and color, realizes that in this pro-

gram of child health and protection, peace has its victories no less than war.

The increased interest and coöperation year after year on the part of children, teachers, parents, and communities, is sufficient proof of the soundness and value of this program.

The number of blue ribbons awarded in 1930 was 7,848; in 1931, 17,704; in 1932, 30,771; and in 1933, despite the depression and lack of funds for securing corrections, there were 38,887 boys and girls in Tennessee's Blue Ribbon army.

Here is what the associate in school health education has been doing.

. . . has written numerous articles, made radio talks, spoken at 5 national, 10 state and 23 district meetings of different organizations, met 105 local clubs and 115 parent-teacher associations interested in public health, appeared before 18 county teachers' associations, talked to the pupils of 468 schools, made 73 visits to 50 counties in Tennessee, and served as Secretary of the Tennessee Conference on Child Health and Protection.

Radio Talks—Active coöperation with local stations in giving talks on popular health topics.

News Releases which have included Special articles released for local newspapers, radio talks, school teachers, doctors, health workers, and others.

Health News—including the monthly *Health Briefs* with about 2,000 circulation, and a bi-weekly *News-Letter*, sent to all full-time health workers in the state.

News letters, leaflets, and publications from other state health departments have been collected and excerpts have been mailed to full-time local workers for their use in educating the public. Through this medium valuable information has been passed on to the local full-time workers. The health officers in the State receive weekly from the U. S. Public Health Service reports which contain valuable scientific information for health workers.

Literature—which includes a supply of pamphlets furnished on request to individuals.

Exhibits—Includes display material

. . . used by the Department for community fairs, public lectures, and have been furnished to school authorities and others who are interested in developing exhibits. Much interest has been manifested in the full-time health departments in preparing exhibits for community fairs. Posters and charts demonstrating the value of sanitation, typhoid inoculations, smallpox vaccinations, toxin-antitoxin or toxoid administration, and other activities have been furnished local health and school agencies.

Lectures and Conferences are given by State Department and county unit staff members

. . . to county medical societies, county courts, parent-teacher associations, federated clubs, civic clubs, school boards, city councils and others interested in promoting an educational program throughout the state. Through lectures, exhibits, newspaper articles, the public has been informed of the advantages of full-time county health work, the value of the State Department of Public Health and its divisions, and a general well rounded program in child hygiene, maternity and infancy, sanitation, and other activities.

Films as well as lantern slides are used.

Annual Conferences of full-time local health workers are held.

Professional Technical Education includes an introductory course at Vanderbilt School of Medicine to graduates in medicine who are interested in becoming full-time health workers.

Courses in public health nursing are given at Peabody and Vanderbilt, and a course for sanitary officers at University of Tennessee.

Would our readers like to read similar reviews of state department activities as they can be gleaned from annual reports? One difficulty would be that we do not receive many such reports.

Health Education Specialists in State Departments—The March 1, 1935, issue of *Public Health Reports*, U. S. Public Health Service, Washington, carries the annual "Directory of State and Insular Health Authorities."

Here we find listed the following full-time workers:

Connecticut bureau of public-health instruction: Elizabeth C. Nickerson, C.P.H.

Illinois division of public-health instruction: Baxter K. Richardson, chief.

Indiana bureau of health education: Bynum Legg, director.

Iowa division of child health and health education: Joseph H. Kinnaman, M.D.

Kansas division of public-health education: Earle G. Brown, M.D.

Kentucky bureau of public health education: John W. Kelly, director.

Maryland committee on public health education: Gertrude B. Knipp, secretary.

Michigan bureau of education: Marjorie Delevan, director; Pearl Turner, assistant director; Melita Hutzel, lecturer.

New Jersey bureau of public health education: Edwin C. Lanigan, chief.

New York division of public health education: B. R. Rickards, director.

Ohio bureau of publicity: Paul Mason, chief.

Pennsylvania division of public health education: J. C. Funk, LL.B.

Philippine publicity section: Jose P. Bantug, Ph.G., M.D., chief.

Texas bureau of public health education: L. E. Bracy.

Wisconsin bureau of education: John Culnan, director.

Fifteen departments and 17 individuals. Is it possible that all the individuals were not listed in the reports to the U.S.P.H.S.?

How about a luncheon or dinner gathering at Milwaukee in October?

Humor as a Teaching Device—Health speakers do use "funny stories." Have we studied the elements which make them an effective tool? All too often the stories merely precede a prosaic presentation of solid fact.

Since the health speaker should be a teacher we offer several paragraphs from "The Use of Humor as a Teaching Device," from *High Points* issued for high school teachers by the New York City Board of Education (March, 1935).

That humor may be used as a valuable teaching device is unquestioned. What is

questioned is not the utility of humor in the classroom but the type and quantity which should be used. Other teaching devices, from the stereopticon to the thought question in Latin courses, have received careful study and close analysis, but no such studies or analyses have been made of humor as a teaching device. In this field all has been left to the individual teacher, abandoning the pupil to his uninstructed judgment.

There is a crying need for a detailed study of the use of humor in the classroom. This article lays no claim to being that study, but merely attempts to raise the question and to call to the individual teacher's attention the necessity of a critical analysis of his employment of humor, with a view toward its revaluation in the interests of more effective teaching and of a happier student-teacher relationship.

Those who have thought about the matter agree that relevancy ought to be the *sine qua non* of humor as a teaching device. The difference between the teacher who skilfully uses humor as a pedagogical aid and the one who merely blunders haphazardly into a joke is largely a difference in their relative will-powers and abilities to resist temptation. The one uses humor as an adjunct to teaching, the other as a substitute for it.

None of the examples quoted by the author happen to touch health topics.

State Health Releases—Below are listed the titles of recent releases to newspapers from several state health departments. To these should be added the radio talks from Illinois and Connecticut, and the releases based on the weekly bulletin of New York State Department. *Probably other state departments issue similar releases.*

Iowa: A great objective (May Day in Iowa); Lending nature a helping hand (measles); Rural health service; Deaths from measles prevented; The laboratory in disease prevention; The attack on Germs; Explains how to "K.O." epidemics; Mottled enamel; Getting at germs; Defenses against disease; Odds against plural birth; Errors of Omission (birth registration).

Maryland: Goals (reducing infant mortality); A message to you (typhoid inoculation); Milk-improved production and increased consumption; Maryland's 500,000 (population under 16 years).

New Mexico: Accidents; From pig to man

(diseases); Bone eaters (primitive racial diet wisdom); Waste (in curing sickness); The precarious age (high school age); The Gosling (goose vs. gander as to coffee and tobacco); We drink (alcohol beverages).

Exhibits in High Schools—A Latin Exhibit at George Washington High School, New York City, was made up of models, drawings, maps, posters, book reports and scrap books.

One exhibit, as described in *High Points* published by New York City Board of Education,

. . . that was particularly instructive was a table set with delicacies to tempt the jaded appetite of a Roman gourmet—honey, wine, nuts, oysters, olive oil, garlic, beef, pork, cheese, milk, eggs, and grapes. The pie-shaped bread on the table was not a relic of Herculaneum, but had been baked by the student responsible for this table. The Latin names of all the foodstuffs on display were shown on cards. A chart which compared food prices during the Empire with present day prices aroused considerable interest and comment.

This description suggests the participation of pupils in all courses in a health and hygiene display.

In the annual Children's Fair held recently at the American Museum of Natural History there were a few health and nutrition displays among a wide range of almost remarkable exhibits. Probably the teachers lacked graphic ideas on health to share with the children. Many three-dimension displays would be possible. It seems likely that the pupils in the social sciences would be interested in picturesque and original methods for depicting statistics and ideas in the health field.

"The Fire Next Door" (fire prevention play for junior high school students), and a radio interview (by Boy Scouts and local fire chief). *Safeguarding America against Fire*, 85 John St., New York, N. Y. Nov. 2, 1934. *Free.*

"How Good a Driver Are You?" is

a highway safety test form issued by Travelers Insurance Co., Hartford, Conn. Six pictures indicate right and wrong methods of driving and walking, the correct ones to be marked "R," 6 pictures show dangerous practices, the reader to indicate whether the driver or pedestrian is at fault; a series of "yes" or "no" questions; a series of factual statements, each in one correct and two incorrect forms.

"How Safely Do You Drive and Walk?" is a 12 page folder with accompanying answer sheet. In 10 cartoons dangerous practices are illustrated with numbered descriptions for the reader to locate. Questions to be checked "yes" or "no" and "How Not to Stay Alive" and "Things Worth Remembering" complete the folder which is distributed by Travelers Insurance Co., Hartford, Conn.

"How Safe Is Home?" by Howard W. Green. A 48 page study of accidents in Cleveland, including maps, diagrams, and tables. Published by Cleveland Health Council, 1900 Euclid Ave., Cleveland, Ohio. 50 cents. Some of the data may be quotable, but it is to be hoped that other cities may duplicate the type of study here illustrated.

We Do Not Cover the Field—Too much is going on; too many people are doing good work; and too few people take the time to help us here to share their successes or failures with health education workers generally. We can report or discuss only what is sent to us.

And frequently essential information is lacking about material sent so that no use can be made of it.

EDUCATION AND REFERENCE

vival"; "Automobile Fatalities Decline among Children: Increase among Adults." *Statistical Bulletin*, Metropolitan Life Insurance Co., New York, N. Y. March, 1935. *Free*.

"Can't Afford the Eight-Hour Day?" provides data for local efforts to change the time schedule for private-duty nurses. *Am. Journal of Nursing*, 50 W. 50th St., New York, N. Y. May, 1935. 35 cents.

"Diphtheria Can Be Eliminated: Immunize the Babies," says Dr. W. H. Park under that heading in *Child Health Bulletin*, Am. Child Health Assn., 50 W. 50th St., New York, N. Y. May, 1935. *Child Health Bulletin*, regularly to members; single specimen copy 10 cents.

"Insects," a list of available publications on insects injurious to man, etc. Supt. of Documents, Washington, D. C. *Free*.

"Report of Progress"—does not look like a report—is a 4 page illustrated folder—several ideas on copy and illustrations. Copy for 5 cents. Committee on 8 Hours for Nurses, 132 E. 45th St., New York, N. Y. Also, "Dr. X Knows Why 8 hours are better than 12"—envelope enclosure—example of "first person statement or testimonial." Copy for 3 cents. Both good for local campaigns.

A "special contraception number" of *American Medicine*, 60 E. 42d St., New York, N. Y. (March, 1935), includes editorials, original articles, and book reviews. Both sides are given a hearing. 25 cents.

Two maps showing the relative rank of the 48 states as to maternal and infant mortality, are offered for exhibit purposes. Address Children's Bureau, Washington, D. C.

"Vegetables in the Diet," by S. L. Smith. The third of a series, this article reviews changed attitudes, and proposes novel promotion methods to utilize the new points of view. Ideas

for exhibits, and for those who seek to enlist the aid of fruit markets, roadside stands, and even the catalogues of seed-men. Paragraphs on needed research will warn writers and speakers against too broad generalizations. *Journal of Home Economics*, 101 E. 20th St., Baltimore, Md., April, 1935. 30 cents.

WHAT OTHERS HAVE DONE

Some of these "ideas" may be adopted or adapted to your own work.

Again *Journal and Sentinel*, Winston-Salem, N. C., in coöperation with City Health Officer Carlton, issued a "Child Health Section," a 16 page tabloid magazine. There are numerous specially written articles by national health authorities. Sample for 2 cent stamp to City Health Dept.

And, too, the *Spectator*, Hamilton, Ontario, has made an annual event of its special health edition, presented in coöperation with the Medical Officer of Health.

In display type the following statement occupies the last page of May, 1935, issue of *Health Bulletin*, North Carolina State Board of Health:

This space is
sorrowfully dedicated
to the memory
of the
6,072

North Carolina Babies
who died during 1934 before
they were one year old

*A Disgraceful Sacrifice of
Infant Life for Which the State
Has No Legitimate Alibi*

Once upon a time a speaker's assigned topic was "Mental Hygiene," but he had it changed to "Inside of Your Head." Which do you prefer, and why?

"The Parson and the Doctor Discuss Leprosy" is an example of conversational copy in health education, one of

several types used in *Jamaica Public Health*, Bureau of Health Education, Kingston. March, 1935.

The recent publication of a "twenty-fifth anniversary edition" of Clifford Beers's *A Mind That Found Itself* resulted in numerous extended book reviews which did an effective job in mental health education.

Some of the community fund or chest posters or placards on health services are particularly well done and supplement the publicity of individual agencies. A recent one on "Healthy Babies" comes from Denver Community Chest.

What is it? Why is it dangerous? What causes it? These and other questions with their answers are found in a 4 page folder on tuberculosis issued by Bellevue-Yorkville Health Center, 325 E. 38th St., New York, N. Y. Is it not possible that the question and answer form might be used every once in a while to give a fresh approach to old material?

"What is Wrong with This? A case report with at least 3 things wrong in its handling!" *Public Health Nursing*, 50 W. 50th St., New York, N. Y. May, 1935. 35 cents. An idea for professional journals and staff conferences. In modified form it seems to offer a method of getting attention to home and community health problems. There is in it a possible newspaper competition.

RADIO

To repeat, the editor of this department earnestly requests full information about mention of venereal diseases in broadcasts.

From the Public Health Committee of the Cup and Container Institute, 30 Rockefeller Plaza, New York, comes a request for copies of radio talks on the sanitary dispensing of food and drinks.

Under this general heading we include talks on tavern and soda fountain sanitation, the

common drinking cup, roadside stand sanitation, and any other aspects of the spread of respiratory diseases through the channels of food and drink dispensing.

When the material has been assembled, we shall be very happy to make copies of the whole set available to you if you should care to have them.

Radio addresses by the Governor General, the Prime Minister, and the Leader of the Opposition, inaugurated the King George V Silver Jubilee Cancer Fund in Canada. The addresses are reported in *National Health Review*, Dept. of Pensions and National Health, Ottawa. April, 1935.

As announced in *Everybody's Health*, St. Paul, Minn.:

With his first broadcast in April this year, Dr. W. A. O'Brien of the University of Minnesota, began his seventh consecutive year delivering weekly health talks over the air under the auspices of the Minnesota State Medical Association. He gave the first in the series April 4, 1928. During these years, the program has become one of the most popular sustaining programs of WCCO, attested to by the ever increasing number of letters received from the radio audience. Requests for a booklet offered at only one broadcast last fall reached over 2,400, believed to be an all time station record for a morning program.

Extracts from the talks by Dr. O'Brien appear in the monthly issues of *Everybody's Health*. The May topics:

Hay fever. Anemia in children. Peptic ulcer. The sixth year molar.

American Medical Assn. (N.B.C., Tuesday, 5 P.M. EDST, or C.B.S., Thursday, 4:30 P.M. CDST):

Sickness insurance. Sudden death. Child health. "Catarrh." May Day or all year 'round? Mothers of America. Training good doctors. Pain. Being your age. Saving our mothers. Children's eyes. Saving our eyesight. Eye accident prevention.

Hartford Tuberculosis and Public Health Society:

Classroom education for healthful living. Work at the Hartford Dispensary. Knowl-

edge alone is not the way to health. Social Service at the Municipal Hospital. A day with the visiting nurse. Guarding the health of 2,300 children. The place of the Y.W.C.A. in the health program of the community. The medical social worker in a hospital. Work of the Juvenile Courts in crime prevention. The health program of the Y.M.C.A. The importance of health in family welfare. The family and home as the unit of community health. Modern weapons in fighting tuberculosis. Mental hygiene.

New York City Dept. of Health, 139 Centre St. ("enclose stamps for postage"):

Quacks and weight reducing. Quacks and tuberculosis. Recreation for every member of the family. Winter babies. Home care of invalids. The shortest day and cod liver oil. Milk gets a boost. Quackery in diabetes. When every cent counts. I am a fanatic about this (covering of coughs and sneezes). "The eyes have it." The autumn of life. Is there a school child in your home? Not everyone wants to reduce. Feeding the family. Food sanitation. The story of diphtheria immunization. The war on mosquitoes. They call them accidents. Common sense and ventilation. Fads and fancies in medicine. What about cancer? Pneumonia. Meet the facts on meat. Hear ye! Hear ye (care of the ears). Measles-time. The six year molars. Speaking of vitamins.

Ohio State Dept. of Health (station WOSU at 10:15 A.M., Thursdays):

Child health as reflected in vital statistics. Child Health Day as a factor in child life. Hospital Day in its relation to child health. Rabies. Occupational diseases.

REPORTING

A miniature line cut, a concise caption, and a date in red. Then another, and another, and more of them irregularly arranged over the two outside cover pages of a report and a flap the size of one page. At the top of the flap which folds back over the front cover page we read: "Meeting Human Needs: 39 Years of Palama Settlement." That reveals the secret. The 3 cover pages tell the story of 39 years; inside is the record of the "39th

Year of Service." The first inside cover page: "Where the Money Came From" and "Where the Money Went," the financial statement. Nearly every page has a hand-lettered script heading printed in red. Again Palama Settlement has done something "different" and decidedly effective. The Settlement is in Honolulu although the report does not say so. Of the \$197,829.97 budget \$30,000 went to recreation, \$53,000 to medical and \$46,000 to nursing services, \$2,300 to diphtheria campaign, and \$34,000 to dental clinic.

"Bright Eyes of 1934" is on the cover page. On the inside cover page: "Twentieth Annual Report of the National Society for the Prevention of Blindness, 50 W. 50th St., New York, N. Y., 1934." The cover carries two bands, across top and bottom, containing baby faces. Dull finish paper and large type make it easy to look at.

Again the Racine, Wis., Health Dept., has issued a mimeographed annual report. On letter size sheets, with printed cover, and a 2-page index (includes reference to "publicity"). An effective form of report.

SAFETY

Ninety-nine thousand deaths by accident last year in the United States are reported in "Preliminary 1935 Edition of Accident Facts." This is a slight decrease from the 1930 all-time high, but is 8.7 per cent increase over 1933. In 9 months "had been drinking" drivers in fatal accidents increased 29 per cent and pedestrians 53 per cent. In non-fatal accidents "had been drinkers" increased 50 per cent, pedestrians 64 per cent. The report doubts that all drinkers were reported. The full report costs 10 cents. National Safety Council, 20 N. Wacker Drive, Chicago, Ill.

Enforcing a safety law by means of motion pictures is reported in *Movie*

Makers, 105 W. 40th St., New York, N. Y. (April, 1935: 25 cents):

The drunken drivers in Flint, Mich., now appear in 16mm. movies, since the Police Department of that city has scenes made of the offenders as they are brought into the police station. This new and remarkable use of the 16 mm. movie camera was initiated as a result of difficulty in getting convictions on charges of driving while drunk. . . .

To solve the problem, the Flint Police Department enlisted the aid of Theo. Brice, ACL, who, with a concealed motion picture camera, made some experimental scenes which were so successful in preserving the evidence of intoxication that the Police Department has installed a permanent, concealed 16 mm. movie camera. . . . Two No. 4 Photofloods illuminate the hilarious subject and a calendar and a clock are so placed as to be included in the shot, to be used later as evidence. It appears that the drunken offenders take little notice of the bright light which is turned on as they stagger across the room. The next day, the majority of them plead guilty when they are told that movies have been made of them the night before, while the offender who insists on an alibi has slight chance when the record is projected.

CHILDREN AND SCHOOLS

"The First Visit to the Dentist," by E. M. Kohlhepp, *Public Health Nursing*, 50 W. 50th St., New York, N. Y. May, 1935. 35 cents. When to visit and pointers in handling children. Good stuff for parent associations and other uses.

"Home-School-Community Relationships" is a 6 page mimeographed pamphlet based on experiences of teachers under these headings: "Some teachers visit homes"; "Parents are invited to school"; "Children take ideas home"; "Mothers' clubs and community groups are helpful"; "The public health nurse is invaluable." Other counties may wish to collect similar material. Cattaraugus County School Health Education Project, 302 Laurens St., Olean, N. Y.

"Home-School Relationships," in "A Project in Rural School Health Educa-

tion," by R. E. Grout. *Quarterly*, Milbank Memorial Fund, 40 Wall St., New York, N. Y.

June 19-21, 1935, is the date for the Eighth Health Education Conference, Iowa City, Iowa. The main theme: "Effective relationships in school health activities." If interested write to Anne Whitney, Am. Child Health Assn., 50 W. 50th St., New York, N. Y. Preceding this conference will be the 9th Iowa Conference on Child Development & Parent Education. Address: Iowa State University, Iowa City, Iowa.

"The School Camp," by H. S. Curtis. *Journal of National Education Assn.*, 1201 16th St., Washington, D. C. April, 1935. 25 cents. An important adjunct to the school.

"Self-selection of Food by Children," by C. M. Davis, M.D. *Am. Journal of Nursing*, 50 W. 50th St., New York, N. Y. May, 1935. 35 cents. How children in the orthopedic ward, Children's Hospital, Chicago, decide what they eat and how much, and how they gain weight, and the hospital saves on food costs.

"The Teaching of Social Hygiene During the Depression," by F. H. Richards. *Journal of Social Hygiene*,

50 W. 50th St., New York, N. Y. March, 1935. 35 cents. The medical director of William Penn High School for Girls, Philadelphia, mentions "the changes in the attitudes of the pupil during the last 5 years" and some of the incidental problems.

In *Hygeia* for May, 1935—*Hygeia*, 535 N. Dearborn St., Chicago, Ill., for May, 1935, contains:

May Day versus diphtheria. Diphtheria a dreaded scourge. What are your health frontiers? The care of the eyes in measles. Your child's face and future (cosmetic surgery). The mosquito (the twelfth parasite). Prenatal care. The menace of radio quackery. The nursing care of the sick child. Louis Pasteur. Why the baby has eczema. The live topic of the dead tooth (5th in a series). Infant foods approved. Eye diseases in adults (a series). New books on health. Questions and answers.

In "School and Health" will be found:

Studying the pupil's health. Health teaching in May. Solving health educational problems. Health without wealth (or added school costs). Pushing posture (by making it pleasing). A convincing experiment (with milk). Combining health habits with the new curriculum. New health books for teachers and pupils.

BOOKS AND REPORTS

Principles of Genetics and Eugenics

—By *Nathan Fasten, Ph.D.* Boston: Ginn, 1935. 407 pp. Price, \$2.80.

The purpose of the author in writing this book is to make the highly specialized subjects of genetics and eugenics more easily understood. Most of it is devoted to genetics; and some of the chapters describe the Inheritance of Acquired Characters, Germ Cells and Heredity, Sex and Its Determination, Monsters and Abnormal Individuals, the Immortal Germ Plasm, Mendelian Principles of Heredity, the Gene Hypothesis, Variation and Species Formation, and the Improvement of Organisms. At the end of the book, a few chapters describe Physical and Physiological Traits, Mental Traits and Social Factors, and Eugenics and Human Betterment. To add to the understanding of the topics, illustrations and figures are freely used; and to the completeness of the book, a comprehensive bibliography, a useful glossary, and a good index, are appended.

Moreover, the book is interesting, well written, and contains a great deal of useful information. It should be found valuable to lay readers who have a little knowledge of biology, to physicians and nurses who should disseminate more freely knowledge for the betterment of the human race, and especially to students to obtain a basic understanding of genetics and eugenics.

FRANCIS LOWELL BURNETT

Mouth Infection—By *Oliver T. Osborne, M.D.* New Haven, Conn.: Published by the Author, 1934. Price, \$2.00.

We regret that we cannot recommend this book. The case histories, which

are not case histories in any sense of the word, might well have been compiled by a layman. The information under the heading "My Conclusions" was common knowledge when the author began writing in 1917. His observations on dental conditions are quaint, with diagnoses such as "terrible pyorrhea, stinking teeth, rotten foul bridge, nasty infected mouth, plenty of odor," etc. The information that "Pivoted teeth are always a menace" will be received with surprise by dentists, as will also the statement that "most fillings of the canals of teeth will allow, sooner or later, distention of the canal. . . ." We cannot believe that the tooth brush is harmful as the author does: "It has been noted in primitive countries that when the bristle tooth brush was introduced into the schools, the children's teeth decayed faster than they ever did before."

The general object of the book, to show the importance of mouth infections and the close relationship between the professions of dentistry and medicine, is commendable. C. F. ELZEA

Sing Sing Doctor—By *Amos O. Squire, M.D.* Garden City, N. Y.: Doubleday, Doran, 1935. 296 pp. Price, \$2.50.

This is a well written and interesting story of the services of the author as consultant, chief physician, and again as consultant at Sing Sing Prison. It opens with an introduction by Lewis E. Lawes, the Warden.

It is evident that Dr. Squire has not been simply a routine doctor but has studied his cases and his duties carefully and has given much thought to what he has seen. As a result of his

experiences he is very much against capital punishment, and has devoted two chapters to a study of the question, giving many cases of failure of justice. The strain upon the prison physician, who for a long time was the only one who had the right to say whether or not a prisoner was insane, was terrific. Even more trying was the necessity of watching executions, giving the signal for the throwing of the switch, and the subsequent postmortems. Finally his daughter persuaded him to resign after he had realized that he had a dangerous "fixation."

The book is intensely interesting, but we can recommend it only to doctors, sociologists, penologists, and to others of mature mind who are interested in and not merely curious about such subjects. We do not believe that it would be wise to recommend it for general reading, and it should be withheld from young and immature people.

The printing and binding are excellent. There are four illustrations showing the prison. MAZÏCK P. RAVENEL

Ten Years of Rural Health Work, Rutherford County, Tenn., 1924-1933—*By W. Frank Walker, Dr.P.H., Director of Health Studies, The Commonwealth Fund. Published and distributed by The Commonwealth Fund, New York, 1935.*

Rutherford County, Tenn., has been notable among rural health units for its broad program and for the persistence of the agencies which have supported the enterprise over more than a decade. This brochure reflects the record over a period during which the technic of rural health administration was being established.

Very few such units can hope to have their record of accomplishment written by so discerning and understanding a friend as Dr. Walker, for he has been familiar with this county's work during its entire history and he has seen its

progress in the light of similar work elsewhere. There is a nice balance in this report as between the tangible, objective records and the proper emphasis on those personalities involved in Rutherford. The forewords by Dr. E. L. Bishop and Dr. H. S. Mustard give a hint of two very effective personalities which have been behind this project. Dr. J. B. Black carries on the tradition: "At the heart of every great enterprise is a personality."

Those who are concerned with the promotion of county health service will profit by this lucid account which has been kept simple and direct but which carries the refined experience of much sincere labor. Here is the story of one community where the job has been well done and where permanence seems assured. REGINALD M. ATWATER

Voluntary Sterilization—*By C. P. Blacker. New York: Oxford, 1934. 145 pp. Price, \$1.75.*

A well organized book, presenting a rational, convincing and timely plea for the need and method of restricting procreation among the mental defectives. The author deals primarily with the legal, social, and hereditary factors of the problem reserving comparatively little space for the technical description of the surgical procedures. The free use of references and statistics imparts an authoritative quality and greatly augments the value of the proposals and discussions. Liberal and intelligent treatment of the objections to sterilization further enhances the merit of the text.

Present economic stress has markedly accentuated the practical importance of negative eugenics so that the serious consideration of the subject is most opportune. Reasonable controversy may exist relative to the efficacy of sterilization as a means of appreciably reducing the incidence of mental deficiency in the next generation, yet it can hardly be

denied that these unfortunates are entirely unfitted and ill-adapted for parenthood in this highly competitive age. It is precisely this class that is unable to make use of mechanical or medicinal contraceptive devices. Surgical sterilization, without unsexing, is undoubtedly the only applicable and certain method of curtailing their fertility.

The reviewer hopes that this excellent book will be widely read by both the laity and profession.

R. S. HOTCHKISS

Growth and Development of the Young Child—By *Winifred Rand, Mary E. Sweeney, and E. Lee Vincent.* (2nd ed.) Philadelphia: Saunders, 1934. Price, \$2.75.

The high character of this useful textbook has been maintained in its second edition. The subject matter has been brought right up to date. A new chapter on biological development is interestingly written and well illustrated. It gives the necessary background to child growth and development. Recent advances in our knowledge of endocrine function and in nutrition add to the value of the volume. The same lucid style and convenient arrangement of chapters with references as appeared in the first edition enhances the value of this new one. The book is recommended especially to nurses, teachers, and others actively engaged in work for the preschool child.

RICHARD A. BOLT

Ideal Health: or The Laws of Life and Health—By *Alexander Bryce, M.D.* Baltimore: Wood, 1935. 330 pp. Price, \$2.00.

This small book with many anecdotes, narrates notions and discusses principles on the value of Food, Drink, Work, Rest, Air, Exercise, Cleanliness, and Clothing, to health; it also emphasizes the need of Regularity and Moderation, and describes the Influence of the Mind

on the Body, and Eugenics—or the Science of Race Culture. The discourse on each subject is prefaced with a law, as "Eat three meals each day of plain, wholesome, nourishing food, at or about the same time," and is summarized in numbered abstracts; and below some of the abstracts, common quotations, as "All work and no play makes Jack a dull boy," are given. Much of the information in the book has been taken from standard works, and is comprehensive and accurate.

Technical terms have been generally avoided in the text, and thus the book may appeal to lay readers; but its purpose is more to interest teachers of personal hygiene, students of medicine, and practitioners, in order that they may become more enlightened and thus diffuse the knowledge of health.

—FRANCIS L. BURNETT

The Art of Public Health Nursing—By *Edith S. Bryan, Ph.D., R.N.* Introduction by *Elnora E. Thomson, R.N.* Philadelphia: Saunders, 1935. 300 pp. Price, \$2.00.

Enough cannot be said in praise of Miss Bryan's contribution to the nursing profession in her new book just off the press. While written primarily for the public health nurse—its interpretation of the cultural, moral, and spiritual concepts of the underlying principles of nursing as an art—one cannot but hope that this book will be within the reach of every woman in the nursing field. The rural public health nurse is especially fortunate in having close at hand knowledge of the many little things that memory often fails to recall when she is occupied with major problems. Its pages supply the mental stimulus to carry on when one is lonely, discouraged, and weighted down by the sight of poverty with all its gloom. Let us own this book, read it often, and be inspired. The printing and binding are excellent.

ELEANOR KEELY

The Romance of Exploration and Emergency First-Aid from Stanley to Byrd. *New York: Burroughs Wellcome & Co., Inc., 1935.*

Messrs. Burroughs, Wellcome & Company need no introduction to Americans. Indeed we feel proud to know that the present senior member of the firm, Sir Henry Wellcome, is an American by birth and education. The firm has done an enormous amount of high class scientific work in research as well as manufacture.

The book before us is frankly an advertisement from the Chicago. Interna-

tional Exposition, 1934. However, it gives a very interesting account of explorers from Stanley to Byrd, richly illustrated and containing reproductions of many autographs.

It is a valuable history and book of reference concerning such men. The fact that so many of these explorers carried the first aid packages put up by the firm sufficiently attests their quality and the confidence reposed in them by governments as well as individuals. Here is an advertisement well worth preserving.

MAZÛCK P. RAVENEL

BOOKS RECEIVED

THE HARVEY LECTURES, 1933-1934. - Delivered under the Auspices of The Harvey Society of New York. Baltimore: Williams & Wilkins, 1935. 262 pp. Price, \$4.00.

OUTLINE OF TOWN AND CITY PLANNING. By Thomas Adams. New York: Russell Sage Foundation. 1935. 368 pp. Price, \$3.00.

TEN YEARS OF RURAL HEALTH WORK. Rutherford County, Tennessee, 1924-1933. By W. Frank Walker. New York: Commonwealth Fund, 1935. 82 pp.

COMMUNITY PROGRAMS FOR SUMMER PLAY SCHOOLS. By LeRoy E. Bowman. New York: Child Study Association of America. 1935. 48 pp. Price, \$.35.

THE FRUSTRATION OF SCIENCE. By Sir Daniel Hall *et al.* New York: Norton, 1935. 144 pp. Price, \$2.00.

SOME NOTABLE EPIDEMICS. By H. Harold Scott. Baltimore: Wood, 1934. 272 pp. Price, \$4.75.

THE DOCTOR'S BILL. By Hugh Cabot. New York: Columbia University Press, 1935. 313 pp. Price, \$3.00.

AIDS TO ANALYSIS OF FOOD AND DRUGS. By

C. G. Moor and William Partridge. 5th ed. Baltimore: Wood, 1934. 322 pp. Price, \$1.50.

EPIDEMICS AND CROWD-DISEASES. An Introduction to the Study of Epidemiology. By Major Greenwood. New York: Macmillan, 1935. 409 pp. Price, \$5.50.

ECONOMIC PROBLEMS OF MEDICINE. By A. C. Christie. New York: Macmillan, 1935. 242 pp. Price, \$2.00.

HAPPY HEALTH STORIES. By Mildred H. Comfort. Chicago: Beckley-Cardy Co., 1934. 159 pp. Price, \$.70.

SOCIAL WORK YEAR BOOK, 1935. By Fred S. Hall, Editor. New York: Russell Sage Foundation, 1935. 698 pp. Price, \$4.00.

SEDGWICK'S PRINCIPLES OF SANITARY SCIENCE AND PUBLIC HEALTH. Rewritten and Enlarged. By Samuel C. Prescott and Murray P. Horwood. New York: Macmillan, 1935. 654 pp. Price, \$4.25.

A NEW ANGLE ON HEALTH. By D. H. C. Given. London: John Bale, Sons & Danielsson, 1935. 158 pp. Price, \$3.25.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

About St. Louis Encephalitis—Reviewing briefly the findings of the outstanding research project conducted upon the St. Louis outbreak of encephalitis (reported in detail in a separate pamphlet), this excellent summary emphasizes the difference between this disease and the endemic form of encephalitis.

ANON. Infectious Encephalitis. Pub. Health Rep. 50, 16:542 (Apr. 19), 1935.

Mortality Rates Up in 1934—Preliminary mortality statistics from 28 states indicate an increase in death rates from 10.5 in 1933 to 10.9 in 1934. This increase, while not large, was widespread, for 22 out of the 28 states showed an increase. Infant mortality was also higher, 58 per 1,000 live births against 56 in 1933. The rates for a number of specific diseases are also reported.

ANON. Mortality in Certain States during 1934, with Comparative Data for Recent Years. Pub. Health Rep. 50, 17:560 (Apr. 26), 1935.

Treatment for Injured Miners—Certain trade and medical unions in Scotland have under consideration a scheme for the formation of an orthopedic association to provide treatment for injured miners. They propose to open a chain of clinics throughout the country, where they will provide massage, sun-ray exposure and other special treatment.

It is estimated that about 7,000 workers are injured annually in Lancashire, many becoming permanently crippled because of inadequate treat-

ment facilities. Should this experiment prove successful a similar one would be introduced for other workers.

ANON. Orthopedic Clinics for Miners in Scotland. Indust. & Labour Inf., 53, 4:110 (Jan. 28), 1935.

Compensable Diseases in New York State—A review of occupational disease claims closed in the State of New York during 1934, with statistics. As compared with 1933 there was an increase of 25 per cent in the number of closed cases. This apparent increase was due to an enlarged schedule of diseases listed in the law as compensable and to an improved method of recording such claims.

ANON. Occupational Poisons and Diseases, New York State, 1934. Indust. Bull., New York State Dept. of Labor 14 (Jan. 1), 1935.

Medical Examination in Japan—The Japanese Industrial Hygiene Association is advocating the extension of legislation which now calls for medical examination twice yearly of all industrial workers living in dormitories connected with factories, to include all workers employed in strenuous work, especially in chemical and heavy industries.

ANON. Industrial Hygiene in Japan. Indust. & Labour Inf. 53, 6:165 (Feb. 11), 1935.

France's Notifiable Diseases —Cases of notifiable diseases in France in 1933 were: lead poisoning, 704; mercury poisoning, 13; poisoning by benzene, 45; X-ray poisoning, 2; total, 764. This total was a decrease of 23 per cent over the previous year. Two

companies were responsible for 65.5 per cent of all cases.

ANON. Occupational Diseases in France. *Indust. & Labour Inf.* 53, 3:85 (Jan. 21), 1935.

Madrid Society for Industrial Hygiene—On January 18, 1935, the Spanish Minister of Labour inaugurated the Madrid Society for Industrial Hygiene, which body will advise the industrial courts on medical matters, and engage in research in silicosis, the indirect results of cranial traumata, and the problems of hernia and self-injury. In addition the society should help to prevent accidents and diseases, and collaborate in vocational training problems.

ANON. Industrial Hygiene Society in Spain. *Indust. & Labour Inf.* 53, 5:143 (Feb. 4), 1935.

Anthrax—There were 23 cases of occupational anthrax notified to the French Factory Inspection Service in 1933, two of which were fatal. Industries responsible for these cases were: wool, 12 cases; hides, 10; and horse-hair, 1. All of the cases were anthrax of the skin in various parts of the body.

ANON. Occupational Anthrax in France. *Indust. & Labour Inf.* 53, 5:143 (Feb. 4), 1935.

Lead and Zinc Processes—Czechoslovakia has under consideration a bill for the purpose of excluding women and young persons under 18 from employment in certain processes in the treatment and handling of lead and zinc, and laying down certain conditions to be observed in regard to the employment of adult male workers in such processes.

ANON. Lead Poisoning in Czechoslovakia. *Indust. & Labour Inf.* 53, 5:142 (Feb. 4), 1935.

Silicosis—The British Home Secretary made an order on January 29, 1935, extending the Various Industries (Silicosis) Scheme, 1931, to cover employment in any operation underground

in hematite iron ore mines. The order was issued under the Workmen's Compensation Acts and comes into force on March 1, 1935.

ANON. Compensation for Silicosis in Great Britain beginning March 1, 1935. *Indust. & Labour Inf.* 53, 7:202 (Feb. 18), 1935.

Infant Growth and Disease—Growth of infants from poor families may be raised to normal levels by adequate medical supervision; most of the delay in growth occurs in the first 12 weeks of life and undergrown children have higher morbidity and mortality rates than normal ones.

BAKWIN, H., and BAKWIN, R. M. The Importance of Medical Supervision during Early Infancy in the Infant Death Rate. *New York State J. Med.* 35, 7:313 (Apr. 1), 1935.

Morbidity vs. Mortality Rates—Age, case incidence, mortality and fatality curves show, for 18 disease groups in a representative population sample, great variations both in the diseases and the age groups. Contrast rather than similarity prevails between case incidence and mortality.

COLLINS, S. D. Age Incidence of Illness and Death Considered in Broad Disease Groups. *Pub. Health Rep.* 50, 15:507 (Apr. 12), 1935.

Industrial Accidents in Rumania—Number of accidents during period totalled 751. Men: 701 (93.3 per cent); women: 50 (7.6 per cent). The largest number of accidents among the women between the ages of 19 and 22 (34 per cent of total number of women) is due to the fact that a relatively large number of unmarried women work in industry. Of the 50 accidents to women, 39 were injuries to extremities, indicating inadequate vocational training. Although the law forbids industrial employment of minors, 3 children under 14 years suffered injuries. Inadequately trained 20 year old wood, mine, and railroad workers contributed 3.7 per cent of accidents. Cause of the

accidents could not be laid to the employer. The frequency of accidents decreases after the 40 year age group, although 18 (2.6 per cent) accidents occurred among men over 65 years of age.

CORUTIU, C. Industrial Accidents Among the Members of the Local Sickness Fund, Cluj. Rumania, During the Period 1919-1930. *Revista de Igiena Sociala*. V, 1 (Jan. 1), 1935.

Mottled Enamel in Texans' Teeth—The Panhandle-West Texas region constitutes the largest mottled-enamel area in the United States. The water supplies of the large cities contain the causative factor in sufficient concentration to constitute an urgent public health problem.

DEAN, H. T., *et al.* Mottled Enamel in Texas. *Pub. Health Rep.* 50, 13:424 (Mar. 29), 1935.

New Deal for Nurses—A fast moving picture of developments in nursing which have come to some parts of this country because of 3,000 new jobs for nurses in the public health field made available through F.E.R.A. funds.

DEMING, D. New Deals for Nurses. *Survey (Midmonthly)* 71, 4:107 (Apr.), 1935.

Measuring Dustiness—Report of the finding of a new instrument for measuring the dust content of air more satisfactorily than any of the previously known methods were able to do. The method is based upon the fact that heated bodies repel dust. When dust laden air is drawn slowly through a chamber traversed by an electrically heated wire, dust is repelled and collects upon the microscope cover-slips which form the wall of the chamber.

GREEN, H. L., and WATSON, H. H. Physical Methods for the Estimation of the Dust Hazard in Industry. Medical Research Council, Special Report Series, No. 199, 1934.

Shops Acts in Great Britain—An outline of such legislation in Great Britain with a simple review of its his-

torical development, and a consideration of its future possibilities. Includes a consideration of the Shops Acts—in England, Northern Ireland, and the Irish Free State. Book is reliable and readable.

HALLSWORTH, J. Protective Legislation for Shop and Office Employees. By George G. Harrap and Co., Ltd. London, 1935. 244 pp.

Babies Still Have Sore Eyes—The instillation of one drop of a germicide has been relied upon with a sense of complacent security too long. In Philadelphia far too much blindness due to ophthalmia neonatorum was found in a survey, and undoubtedly the same conditions exist elsewhere.

LEHRFELD, L. Limitations in Use of Silver Nitrate in Prevention of Ophthalmia Neonatorum. *J.A.M.A.* 104, 17:1468 (Apr. 27), 1935.

Toward the Solution of Social Medical Problems—In Mr. Milbank's answer to the caustic criticisms of organized medicine directed against the Fund's "lay" participation in the study of medical care, he presents an excellent distinction between health education and propaganda which all in the health field might well keep in mind.

MILBANK, A. G. The Relationship of the Milbank Memorial Fund to the Field of Health and the Medical Profession. *Milbank Quart.* 13, 2:99 (Apr.), 1935.

Diphtheria and Immunity—Occasional cases of diphtheria among Schick negative individuals lead these British authors to the conclusion that, though the principles underlying diphtheria immunization are sound, the antitoxic level needed to insure safety from virulent strains of diphtheria is higher than that indicated by the present Schick level. The need of higher degrees of immunity is suggested.

PARISH, H. J., *et al.* The Schick Test and Active Immunization in Relation to Epidemic Diphtheria. *Lancet*, 1, 11:600 (Mar. 16), 1935.

New Kind of Nursing Campaign—How the Visiting Nurse Association and the Board of Health combined forces to reduce the deaths due to pneumonia in Detroit.

SARGENT, E. A. Detroit's Pneumonia Nursing Campaign. *Pub. Health Nurs.* 27, 4:190 (Apr.), 1935.

Desired and Accidental Pregnancies—The past history of the contraceptive practices of a large group of women attending a New York birth control clinic was studied to reveal the results of their efforts to prevent or to induce conceptions. An interesting finding is that the ability to conceive does not decline with age or increasing order of pregnancy in the pre-menopause period.

STIX, R. K., and NOTESTEIN, F. W. Effectiveness of Birth Control. *Milbank Quart.* 13, 2:162 (Apr.), 1935.

Court Rulings on Pasteurization—Decisions are quoted which demonstrate that the courts realize the practical value of pasteurization in protecting the public health from milk-borne disease.

TOBEY, J. A. Pasteurization and the Courts. *New Eng. J. Med.* 212, 14:613 (Apr. 4), 1935.

More Uncomfortable Mortality Statistics—Though mortality rates in the 86 large cities were higher in 1934 than in 1933 or 1932, accidental deaths, tuberculosis, and the diseases of childhood are down; it is the diseases of middle life and old age that are up. A special survey in 10 cities showed the death rates to be 43 per cent higher among those families without a full-time worker than in those in which there was a full-time worker.

WIEHL, D. G. Recent Trends in Mortality in the United States. *Milbank Quart.* 13, 2:122 (Apr.), 1935.

Social Services Help to Maintain Health—Reporting a statement of the Minister of Health concerning the effect of social services in maintaining Great Britain's health. Despite prolonged unemployment, health in Great Britain has been maintained at a high level, as the result of the work of various agencies: health, unemployment, widows' and orphans' and old age insurance, public assistance, and public health services.

YOUNG, H. S. Social Services and Health in Great Britain. *Indust. & Labour Inf.* 53, 2:47 (Jan. 14). 1935.

ASSOCIATION NEWS

THE MILWAUKEE ANNUAL MEETING

OCTOBER 7-10

INSIDE INFORMATION ABOUT PROGRAMS

REQUESTS for program outlines and program information are frequent in the headquarters office these days.

The Section Secretaries are busy sifting new material and front-rank speakers from the many papers offered and invited. They feel that so much refinement of their programs is possible and desirable, in order to take advantage of the best material available, that it is unwise to make exact announcements at this time.

It is possible, however, to list some of the topics with which the delegates to the 64th Annual Meeting will be concerned during the week of October 7.

Mental Hygiene has been forging ahead so steadily in interest that an entire session will be devoted to it this year for the first time. Four papers and a discussion period are planned. Mental Hygiene from the point of view of the Province, the U. S. Public Health Service, the city health department, the health officer, and the school physician will be presented by outstanding health officials and psychiatrists.

Papers on Economic Consequences of Ill Health, on Health Department Functions—preventive, nursing, medical care, dental care, hospitalization and maternity care—and the Health Department Relationship to the Activities of the Welfare Department and of the Medical Profession will make up the program of the Special Session on the health department and the social security program. The contributors here will be health officers, economists, practising physicians, welfare directors, and officers of government.

The Fifteenth Anniversary of the Association's Committee on Administrative Practice is to be commemorated by a program in which those who have been most intimately connected with its development will review its history and accomplishments, detail the present status of its work, and cast an eye ahead upon its hopes for the future. An especially interesting paper will be a prominent city health officer's evaluation of the committee's past and present activities.

Dr. E. L. Bishop, President of the A.P.H.A., and Dr. Walter E. Brown, President-Elect, are always worth listening to, speaking as they do from a wealth of practical experience and personal philosophy. Dr. Bishop will be the main speaker at the first General Session on Monday evening, October 7, and Dr. Brown at the Banquet Session on Wednesday.

Professional Education is the subject for discussion at a luncheon meeting on Wednesday. Those who attended the very successful dinner meeting under the auspices of Dr. Leathers's Committee on Professional Education at Indianapolis—a session which gathered a large and distinguished audience—know the interest that exists in the education and training of health workers. The committee is prepared this year to make some important announcements of policies. Particularly in view of the new personnel that will certainly be drawn into public health work with the passage of the Social Security Bill, the determination of what constitutes adequate preparation for a

career in public health is of paramount concern.

Another luncheon session, now traditional at Annual Meetings, is the one devoted to Diphtheria Immunization. A committee representing the Health Officers and Laboratory Sections is at work and will present a report covering practices, experiences, and results during the year.

The many allied organizations and special groups that meet with the American Public Health Association add interest and variety to the proceedings. Joint sessions are being arranged by various Sections with the American Association of School Physicians, the International Association of Dairy and Milk Inspectors, the Association of Food and Drug Officials, the Conference of State Sanitary Engineers, the American Association of State Registration Executives. The Association of Women in Public Health, Delta Omega, Johns Hopkins, Massachusetts Institute of Technology and Harvard Alumni, and the Conference of State Laboratory Directors will dine, lunch or breakfast and confer.

The International Society of Medical Health Officers, of which Dr. John P. Koehler, Chairman of the Milwaukee Local Committee, is President, promises a large dinner party on Tuesday evening to which free tickets will be distributed to several hundred delegates. The after-dinner program will be brief, but impressive.

The 10 Section programs reflect present-day attitudes and are thoroughly infiltrated with social and economic significance. The federal health program is given a large share of attention, and its possibilities and implications are thoroughly covered. Picked at random, the following of the other hundred odd subjects will indicate the breadth and scope of Section activity:

Public Health Significance of Poisonous Substances in Foods

A Planned Milk Control for State and Nation
Standard Methods for the Examination of Shellfish
An Improved Agar for Use in Making Bacterial Counts from Milk
Proposed Changes in Standard Methods for Bacteriological Examination of Milk
Whooping Cough and Measles
Mentality and Morbidity
Pneumonia as a Community Health Problem
Child Health at Different Levels
Growth and Nutrition
Health Training and Instruction in Schools
Scarlet Fever
Animal Diseases Affecting the Public Health
Recent Progress in Biological Products
Customer Demand for Vital Statistics
Sanitation in Rural and Recreational Areas
Air Conditioning and Industrial Health
Occupational Diseases
Present Status of the Vitamin B Complex
Food Advertising under the Food and Drugs Act
Maternal and Neonatal Hygiene
Adequate Health Service for the Child
Commercial Advertising's Challenge to Health Education
Community Organization for Health Education
F.E.R.A. Problems
Typhoid Carriers
Institutional Outbreaks of Pneumonia

The preliminary program will be published in full in the September *Journal*. Watch for it, but do not wait until then to make your plans to attend the 64th Annual Meeting in Milwaukee, October 7-10.

ABOUT ENTERTAINMENT

FROM Dr. John P. Koehler, Chairman of the Milwaukee Local Committee, comes the following abbreviated and, he informs us, incomplete, table of entertainment events planned for delegates to the 64th Annual Meeting:

Sunday, October 6, 3 to 5 P.M. A "Milwaukee Kermis" at the Wisconsin Club. Appropriate music will be furnished and light refreshments. Milk, tea, coffee and beer will be served.

The purpose of the Sunday afternoon party is to provide the opportunity for members

to meet local people, to renew acquaintances in the Association, and to make new friends. It will be entirely informal. The Program Committee hopes the music will be the beloved *Deutsches Lieder*, sung by waiters garbed to create the proper atmosphere.

Monday, October 7, 10:30 to 1 A.M. Dancing in the beautiful Ball Room of the Hotel Schroeder, following the first General Session

Tuesday, October 8, 6 to 8:30 P.M. A dinner at the Schroeder Hotel through the courtesy of a Chicago sponsor, by the International Society of Medical Health Officers to the Members of the Governing Council, attending health officers and their friends.

The attendance is limited by the capacity of the dining room, which is approximately 600. Members of the Governing Council, prominent guests and Officers of the Medical Health Officers' Society will first be supplied with tickets, and the remaining tickets will be given out on the basis of "first come, first served" at the registration desk.

Wednesday, October 9, 3:30 to 5:30 P.M. A large, general entertainment feature for all the delegates and their friends—probably a boat ride.

The Program Committee has arranged no scientific sessions for Wednesday afternoon to permit a period of relaxation and recreation.

Wednesday, October 9, 11:00 P.M. to 1:00 A.M. Dancing following the Banquet.

At various times all through the week, inspection trips will be scheduled. Visits to the County Institutions, Health Centers, Sewage Disposal Plant, certified farms, park systems, and, of course, the breweries, are planned.

The entertainment program has been arranged by Dr. Koehler's Sub-Committee on Entertainment, of which Dr. B. L. Corbett is Chairman.

RAILROADS AND HOTELS

THE railroads have granted the Association's request for reduced convention fares to Milwaukee on the identification certificate plan. Rates from various central points and full information about the use of the certificates will be published in the *July Journal*. The pink slips identifying members will be mailed in August.

Milwaukee has many fine hotels with reasonably priced accommodations. A list of them with single and double room rates will be printed in the *July* issue. A coupon for making reservations will also appear.

CORRECTION

ON page 342 of the March, 1935, *Journal*, in Table III of "Public Health Degrees Granted in 1934," an error was made—the dagger indicating that public health courses were discontinued in 1934 should not appear after University of Michigan. These courses are continuing.

CULTURES IN THE DIAGNOSIS OF TUBERCULOSIS

IN the December, 1934, *Journal* there was an editorial under the title "Cultures in the Diagnosis of Tuberculosis." This commented on the work

of Evelyn M. Holmes, of England, as reported in a paper entitled "The Value of Culture in the Solution of Problems of Tuberculosis," in the *Journal of State Medicine* for October, 1934, page 561.

The author has asked us to publish a correction in the formula as given in the original publication, which is that the magnesium sulphate should be 0.04 per cent, instead of 0.4 per cent. The formula follows:

Potassium sulphate	0.4 per cent
Magnesium sulphate	0.04 per cent
Magnesium citrate	0.1 per cent
Asparagin	0.6 per cent
Glycerine	2.0 per cent
aq. destill	

NEW MEMBERS

IN reporting below the latest group of applicants for membership in the American Public Health Association, the Committee on Fellowship and Membership wishes to take this opportunity of recording its appreciation of the efforts of the New York State Department of Health resulting in so many applications, and to urge other state and city health commissioners to make a similar attempt to increase the number of members in the Association. As Dr. Thomas Parran, Jr., has aptly stated: "Membership in the American Public Health Association is a real asset to all of us who are in public health work as a career. The only vigor or vitality any association of this kind can have is that asserted by its membership. Each year a number of members are lost through death, resignation, etc. These

vacancies must of necessity be filled from the younger and the more recent additions to the profession. It is therefore of importance that each year a definite and concerted effort be made to enroll as new members those who are interested in public health who are not already a part of this organization. It seems to me that this is a proper activity of the state and larger city departments. Certainly we should do our part to encourage all public health workers in the state to be aligned with their own national organization."

If any of our constituents are interested in helping the Association expand, the Committee on Fellowship and Membership will gladly furnish them with the necessary material and any other assistance they may require.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Charles A. Bailey, M.D., Apartado 679, Mexico, D.F., Mex., Field Director, Rockefeller Foundation
 J. Douglas Barry, M.D., 205 Nelson Ave., Peekskill, N. Y., Health Officer
 Angel de la Garza Brito, M.D., Ave. Alvaro Obregon 190 A, Mexico City, Mex., Supervisor General, Dept. of Health
 F. F. Chaya, M.D., 22 Main St., Yorkville, N. Y., Health Officer
 Roy L. Cleere, M.D., 424 State Office Bldg., Denver, Colo., Secretary and Executive Officer, Colorado State Board of Health
 Dr. C. E. Elkins, 92 Andrews St., Massena, N. Y., Health Officer
 Henry E. Elwood, Jr., M.D., 144 E. First St., Corning, N. Y., Health Officer
 Earl H. Engel, M.D., 114 Maple St., Wyandotte, Mich., Health Officer
 Daniel C. Fisher, M.D., Clarence Center, N. Y., Assistant District State Health Officer

Louis H. Fligman, M.D., 401 Power Block, Helena, Mont., Member, State Board of Health
 Charles C. Gans, M.D., Community Hospital, San Mateo, Calif., Director, Public Health and Welfare, San Mateo County
 Joseph P. Garen, M.D., 140 N. First St., Olean, N. Y., City Health Officer
 Burton A. Hall, M.D., Oxford, N. Y., Health Officer
 Edgar C. Harper, M.D., Abingdon, Va., Deputy Director of Rural Health, State Health Dept.
 Charles R. Haskin, M.D., 12 Vincent Ave., Chautauqua, N. Y., Health Officer, Chautauqua Institution
 George A. Hays, M.D., State Dept. of Health, Jefferson City, Mo., Director, Rural Health Work
 M. R. Kukuk, M.D., 2405 Franklin Ave., Toledo, O., Lucas County Health Commissioner

Frederick S. Leeder, M.D., D.P.H., 117 Crescent St., Allegan, Mich., Director, Allegan County Health Dept.
 Charles Lipsky, M.D., 162 Howard Ave., Brooklyn, N. Y., Medical Inspector, Bureau of Child Hygiene, Dept. of Health
 Gregory D. Mahar, M.D., 302 City Hall, Syracuse, N. Y., Commissioner of Health
 Thomas A. McGrath, M.D., 10 John St., Hoosick Falls, N. Y., Health Officer
 John G. Norris, M.D., St. Joseph, La., Director, Tensas Parish Health Unit
 Byron L. Pampel, M.D., Livingston, Mont., Member, State Board of Health
 John M. Quinn, M.D., 41 S. Corona Ave., Valley Stream, N. Y., Health Officer
 Dr. Domingo F. Ramos, Direccion de Sanidad, Havana, Cuba, Director of Sanitation
 George L. Rianhard, City Hall, Coral Gables, Fla., Health Inspector
 Ardeen E. Richmond, M.D., Wayland, N. Y., Health Officer
 Rudolph Ruedemann, Jr., M.D., State Dept. of Health, Albany, N. Y., Medical Consultant, Division of Social Hygiene
 Edwin H. Schorer, M.D., City Hall, Kansas City, Mo., Director of Public Health
 Leigh A. Simpson, 11 S. 3rd St., Fulton, N. Y., Health Officer
 Ralph B. Smallman, M.D., Corfu, N. Y., Health Officer
 Albert F. Soch, M.D., 40 E. Main St., Fredonia, N. Y., Health Officer
 Edgar E. Stewart, M.D., 25 Maple Drive, Great Neck, N. Y., Health Officer of Villages of Great Neck Estates
 Sidney S. Wasserstrom, M.D., 1877 Ocean Ave., Brooklyn, N. Y., Medical Inspector, New York City Health Dept.
 Joseph Weinstein, M.D., M.S.P.H., 783 Fox St., New York, N. Y., Assistant District Health Officer, New York City Health Dept.
 James W. Young, M.D., 9615 Brighton Way, Beverly Hills, Calif., Assistant Health Officer
 Alexander Zabin, M.D., 11 Nottingham Rd., Malverne, L. I., N. Y., Health Officer

Laboratory Section

William Antopol, M.D., Bayonne Hospital, Bayonne, N. J., Pathologist and Director of Laboratories
 Joseph O. Collins, M.D., Waterbury Hospital, Waterbury, Conn., Director, Hospital Laboratory
 Israel Davidsohn, M.D., 2750 W. 15th Place, Chicago, Ill., Pathologist, and Director of Laboratories, Mt. Sinai Hospital
 John V. Donnet, M.D., 57 West 57 St., New

York, N. Y., Member of Committee on Clinical and Pathological Laboratories
 Frederick Eberson, M.D., Ph.D., Dept. of Public Health, San Francisco, Calif., Epidemiologist, Bureau of Communicable Diseases
 John J. Engelfried, M.S.P.H., University Hospital, Ann Arbor, Mich., Student, Contagious Laboratories
 Maxwell J. Fein, M.D., 50 Greene Ave., Brooklyn, N. Y., Pathologist, U. S. Army
 Patricia Fleming, B.S., State Dept. of Public Health, Springfield, Ill., Bacteriologist, Division of Laboratories
 E. D. Furrer, M.D., 130 E. Broadway, Eugene, Ore., City Bacteriologist
 McLeod Gillies, M.D., Mountain State Hospital, Charleston, W. Va., Laboratory
 Alfred E. A'C. Hudson, D.Sc., Lee Memorial Hospital, Fort Myers, Fla., Director of Laboratories
 Clarence M. Hyland, M.D., 4614 Sunset Blvd., Los Angeles, Calif., Director of Laboratories, Children's Hospital
 Joseph A. Kasper, M.D., Herman Kiefer Hospital, Detroit, Mich., Director, Bureau of Laboratories, Dept. of Health
 Ludwig Lindberg, M.D., 1407 S. Hope St., Los Angeles, Calif., Pathologist
 Dr. Thomas B. Magath, Mayo Clinic, Rochester, Minn., Division of Clinical Pathology, Dept. of Parasitology
 George R. Moffitt, Harrisburg Hospital, Harrisburg, Pa., City Bacteriologist and Chemist
 Gertrude Moore, M.D., 2404 Broadway, Oakland, Calif., President-Secretary, Western Laboratories
 Frederick W. Shaw, M.D., Medical College of Virginia, Richmond, Va., Professor of Bacteriology and Parasitology
 Philip L. Varney, Ph.D., Washington University School of Medicine, St. Louis, Mo., Instructor, Dept. of Bacteriology and Public Health

Vital Statistics Section

May A. Burgess, Ph.D., 4615 Livingston Ave., New York, N. Y., Volunteer study in field of growth statistics
 Ernest G. Carscallen, A.B., 903 N. Broadway, Baltimore, Md., Student Assistant, Dept. of Biostatistics, Johns Hopkins School of Hygiene and Public Health

Public Health Engineering Section

John C. Cochrane, Jr., 605 Hardy & Hayes Bldg., Pittsburgh, Pa., Engineer, Wallace & Tiernan Co.
 Thomas M. Riddick, M.S., 1920 Osborne

Place, New York, N. Y., Sanitary Engineer
 Embert H. Sprague, B.S., University of
 Maine, Orono, Me., Professor of Sanitary
 Engineering

Industrial Hygiene Section

Elmer G. Balsam, M.D., Box 1324, Billings,
 Mont., Member, State Board of Health
 William B. Fulton, M.D., Dept. of Labor &
 Industry, Harrisburg, Pa., Chief, Industrial
 Hygiene, Bureau of Industrial Standards
 S. Edward King, M.D., 33 Fifth Ave., New
 York, N. Y., Medical Director
 Fredia Patten, R.N., Southern Alkali Corp.,
 P. O. Box 1591, Corpus Christi, Tex., In-
 dustrial Nurse
 Max Trumper, Ph.D., 920 Medical Arts Bldg.,
 Philadelphia, Pa., Consultant in Industrial
 Toxicology

Food and Nutrition Section

Robert McD. Allen, 122 Hudson St., New
 York, N. Y., President, Vegex Inc.

Child Hygiene Section

Edith M. Buyer, M.D., Albert Leonard
 Junior High School, New Rochelle, N. Y.,
 School Medical Supervisor, Board of Edu-
 cation
 Jean M. Henry, Wellington Hotel, Albany,
 N. Y., Consultant Nurse

Public Health Education Section

Edwin C. Braynard, M.D., 47 Highland Rd.,
 Glen Cove, N. Y., Health Officer, East
 Hills, N. Y.
 Eugene A. Fierro, M.D., 320 E. 57 St., New
 York, N. Y., Instructor in Public Health,
 New York Homeopathic Medical College
 & Flower Hospital
 Hugh G. Henry, M.D., Germantown, N. Y.,

Prenatal Clinics and Luetic Clinics, Colum-
 bia County Dept. of Health
 Irwin I. Lubowe, M.D., 505 West End Ave.,
 New York, N. Y., Practising Medicine
 Eunice I. Nickerson, C.P.H., 488 Whitney
 Ave., New Haven, Conn., Research As-
 sistant in Public Health, Yale University
 James H. Stone, C.P.H., Williamsburg, Va.,
 Instructor in Bacteriology and Public
 Health, College of William & Mary

Public Health Nursing Section

Mary B. DeLas, Indianola, Miss., Public
 Health Nurse
 Bertha Jenkins, R.N., Saanich Health Dept.,
 Royal Oak, B.C., Canada, Supervisor,
 Health Dept.
 Mary E. Wiseman-Herndon, R.N., Perry,
 Fla., Public Health Nurse, Taylor County

Epidemiology Section

Harry L. Chant, M.D., 4 Jewett Parkway,
 Buffalo, N. Y., Epidemiologist-in-training,
 State Dept. of Health
 Samuel Hyman, M.D., 556 Park Ave., Albany,
 N. Y., Epidemiologist-in-training, State
 Dept. of Health
 Mildred E. Shellig, M.D., 395 Myrtle Ave.,
 Albany, N. Y., Epidemiologist-in-training,
 State Dept. of Health
 Dr. Frutos Solon Nunez, San Jose, Costa
 Rica, Minister of Health

Unaffiliated

Margaret Bullowa, 62 W. 87 St., New York,
 N. Y., Medical Student, New York Uni-
 versity Medical College
 J. Louis Neff, 1527 Franklin Ave., Mineola,
 N. Y., Executive Secretary, Nassau County
 Medical Society

CLOSING DATE FOR FELLOWSHIP APPLICATIONS

THE Committee on Fellowship and
 Membership wishes to announce
 that August 1 is the closing date for
 accepting Fellowship applications for
 action at the Milwaukee Annual Meet-

ing. Eligible members who desire to
 apply for Fellowship this year are re-
 quested to submit their applications to
 the committee as much in advance of
 August 1 as possible.

Report on a Meeting to Discuss Standard Methods for the Examination of Shellfish

AT the request of C. A. Perry, Referee for the Laboratory Section on Laboratory Methods for the Examination of Shellfish, a conference was called at the Army Medical Center in Washington, D. C., on April 18, 1935. The following were present: L. M. Fisher, Chairman of the Committee on Shellfish of the Public Health Engineering Section, A. C. Hunter, representative of the Food and Nutrition Section, A. P. Hitchens, Chairman of the Coördinating Committee on Standard Methods and R. S. Breed, Chairman of the Committee for the Examination of Dairy and Food Products for the Laboratory Section, W. R. Berry, R. Messer, R. E. Tarbett, and others interested in the sanitary control of shellfish.

Under the leadership of Dr. Perry there was a full discussion of the nature of the control that should be exercised over shellfish production areas; the type of laboratory examination that should be carried out for oysters in the shell, shucked oysters, and other shellfish; and of the type of examination that should be made on oysters after they are received in consuming centers.

It was pointed out that in the preparation of any comprehensive report on methods of controlling the sanitary condition of oysters and other shellfish there should be a discussion of the

biology of shellfish so far as it has a bearing on the sanitary condition of the water in which these shellfish live. There was a general feeling that if the entire shell contents of the oyster are used as a source of the sample the results of the laboratory examinations would be more valuable, and that the laboratory methods should be such as would distinguish between *Escherichia coli* and other members of the colon group.

It was pointed out that there was genuine need for the preparation of a comprehensive report on shellfish examinations which would cover not only pertinent facts regarding the biology of shellfish and the sanitary condition of production areas, but also laboratory methods for the examination of oysters and other shellfish as shipped, and after receipt in consuming centers. It was not felt that the information at hand justified the fixation of definite sanitary standards. Objection was made to the fixation of absolute standards by the American Public Health Association on the ground that the existence of definite standards might embarrass official control agencies in legal procedures. On the other hand, all agreed that limits of pollution could be given for oysters and oyster waters in the form of carefully phrased recommendations.

Meeting of the Committee on Standard Methods for the Examination of Dairy and Food Products

THE Laboratory Section Committee covering Standard Methods for the Examination of Dairy Products met April 8, 1935, at Geneva, N. Y., with the following referees present: F. C. Blanck, Referee for Chemical Methods, A. H. Robertson, Referee for Methods of Counting Bacteria, Mac H. McCrady, Referee for Methods of Detecting Specific Types of Bacteria, G. J. Hucker, Associate Referee for Methods of Identifying Streptococci, R. S. Breed, Chairman.

There was some discussion over the need for methods for determining total solids in plain ice cream and for determining small amounts of nutritionally important minerals in milk. Dr. Blanck, speaking as President of the Association of Official Agricultural Chemists, and as a member of the committee, expressed the satisfaction of the A.O.A.C. with the present arrangement regarding the publication of *Standard Methods of Milk Analysis*.

Discussion developed the need for broadening the scope of the present report to cover the examination of dairy products other than milk and this led to the suggestion that the title of the next edition of the report should be "Standard Methods for the Examination of Dairy Products" rather than "Standard Methods of Milk Analysis." Only methods of value in official control work are to be included, however, in order that the report may continue as authoritative in its own field.

Consideration was given to methods

of securing more satisfactory incubation procedures in public health laboratories that are using the standard agar plate count, and to the problems that will arise if an agar of more satisfactory composition is substituted for the meat extract-peptone agar now in use.

It was reported that only minor criticisms and suggestions have been received thus far regarding the methods suggested by W. A. Hagan and I. F. Huddleson for detecting the presence of tubercle and Bang's disease organisms in milk. The section in the present report giving tentative methods for the detection of organisms of the colon group was discussed from various standpoints. Research work is showing more clearly than ever that the presence of organisms of the colon group in milk and dairy products does not have the significance that the presence of organisms of the colon group in water and sewage has. Effective use is being made of tests for organisms of this group in detecting inefficient pasteurization and in the control of recontamination of milk during the bottling process.

Through A. H. Robertson, who is also Chairman of the Committee on Bacteriological Methods of the International Association of Dairy and Milk Inspectors, a questionnaire covering the new ice cream section of the *Standard Methods of Milk Analysis* is being sent to the list of individuals and laboratories interested in this type of work that is maintained by the American Public Health Association.

Committee on Professional Education Meeting

A MEETING of the Committee on Professional Education was held in New York on May 4. This committee is one of the Five Standing Committees of the Association and is charged with carrying out studies for development of standards for professional education in public health work.

The committee and its various sub-committees have been giving consideration to the problem of educational qualifications of health officers, public health engineers, sanitarians, and public health nurses.

A draft of the Second Report on the Education and Qualifications of Health Officers was circulated to a list of about 200 members of the Association, and comments were received from 75, indicating the widespread interest in this subject. It was particularly significant to note the thoughtful consideration which the report provoked and the helpful suggestions made by many of the commentators.

Committee reports were unanimously adopted bearing on the education of health officers and public health engineers, and a report on the educational qualifications of sanitarians was brought up to the point of final revision. Progress reports were received from other sub-committees who are interested in different professional groups, including vital statisticians, health edu-

cators, and public health nurses. These reports will be presented through the Executive Board to the Governing Council at the Annual Meeting.

It was reported by the Sub-Committee on the Training of Undergraduates in Medical Schools that visits are now being made by representatives of leading medical colleges to the departments of preventive medicine of selected schools throughout the country, giving an opportunity for the exchange of ideas, methods of presentation of material, and suitable technic for teaching preventive medicine in medical schools.

The committee is planning to hold a special luncheon session at the Milwaukee Annual Meeting, and an interesting program is being developed. It is felt that the work of this committee is of such importance to the future of public health work that opportunity should be given to the membership to familiarize itself with its activities.

It is believed that the steps taken at the May meeting were highly important, reflecting as they do the long continued interest in this field by the American Public Health Association, and the intensive review of professional education given by a large number of specially qualified members of the Association.

NEWS FROM THE FIELD

DR. REYNOLDS NEW SURGEON GENERAL OF ARMY

COLONEL Charles R. Reynolds, Surgeon of the Army's Second Corps Area, at Governors Island, N. Y., was nominated by President Roosevelt for Surgeon General of the Army, with the rank of major general. He will succeed Major General Robert U. Patterson, whose term expires June 1.

Colonel M. A. Shockley, Commander of Letterman General Hospital at the Presidio in San Francisco, was nominated by the President as Assistant Surgeon General with the rank of brigadier general.

ARIZONA ASSOCIATION ELECTS OFFICERS

AT its meeting on April 24, the Arizona Public Health Association elected the following officers:

President—A. N. Crain, M.D., Phoenix

First Vice-President—Lydia Pothoff, Nogales

Second Vice-President—F. C. Roberts, Jr., Phoenix

Secretary-Treasurer—Jane H. Rider, C.E., Tucson

The next annual meeting of this organization will be held in April, 1936, at Tucson, Ariz.

DRINKING WATER

TRAVELERS will be interested to know that the sources of drinking and culinary water used on interstate railroads, buses, vessels, and airplanes are inspected and certified by the U. S. Public Health Service. Ninety-four per cent of these supplies were inspected and certified during the year. It was found necessary to prohibit the use of 28 of these supplies.—*New York State J. Med.* 35, 3:116 (Feb. 1), 1935.

MARYLAND-DELAWARE SEWERAGE CONFERENCE

AT the Ninth Annual Conference of the Maryland-Delaware Water and Sewerage Association, which was held at the State House, Annapolis, May 16-17, Prevention of water pollution, Comprehensive planning for water supply and sewerage systems, and other engineering problems of special concern to state, city, and county departments of health were discussed.

PENNSYLVANIA SEWAGE ASSOCIATION MEETS

THE Ninth Annual Conference of the Pennsylvania Sewage Works Association will be held at State College, Pa., June 24-26. Numerous papers of importance will be presented.

FREDERICK L. HOFFMAN RETIRES

AFTER 42 years of service with the Prudential Insurance Company of America, during which time he acquired international recognition as a foremost statistician, Frederick L. Hoffman, LL.D., a member for 28 years and a Charter Fellow of the A.P.H.A., was retired from active duty on May 1.

Dr. Hoffman, who was born in Varel, Grand Duchy of Oldenburg, Germany, on May 2, 1865, came to this country when he was 19 and after a brief mercantile experience became associated with the Metropolitan Life Insurance Company. In 1891, he became affiliated with the Life Insurance Company of Virginia and 2 years later became Statistical Assistant in the Prudential's Actuarial Department. His literary contributions to insurance, statistics, and social science have numbered scores and he has appeared as an authoritative

lecturer on insurance and public health subjects before leading universities throughout the country, some of his notable works being devoted to cancer, tuberculosis, statistics, malaria, radium necrosis (mesothorium), earthquake hazards and aviation.

In 1934, Dr. Hoffman, with the consent of the Prudential, presented to the Cancer Research Laboratories of the University of Pennsylvania Graduate School of Medicine his library on that subject and it was hailed as a notable event in the medical history of Philadelphia in an official statement by the *Pennsylvania Gazette*.

Dr. Hoffman does not intend abruptly to abandon his work. After a needed vacation he will continue his research on cancer, maintaining an office in the Laboratories of the University of Pennsylvania.

SUMMER TOUR

THE Health Section of the World Federation of Education Associations is arranging a European travel and study tour in connection with the Federation meeting at Oxford, England, August 10-17. Leaving New York June 29, the tour will visit France, Switzerland, Germany, Poland, Russia, Finland, Sweden, Denmark, and England. The group will meet leaders in school health in these countries.

Write for information to Professor C. E. Turner, Massachusetts Institute of Technology, Cambridge, Mass.

RESIGNATION OF MR. KINGSBURY

JOHN A. Kingsbury, LL.D., Fellow and Life Member, American Public Health Association, has resigned as Secretary of the Milbank Memorial Fund of New York. Mr. Kingsbury has served as Secretary with the Fund since 1922 and for the last year has been a member of the Board of Directors of the Fund. During his administration a very definite trend of increased in-

terest toward public health activities has been noted and there has been created a technical staff of national distinction. During Mr. Kingsbury's tenure, Edgar Sydenstricker became Director of Research. I. S. Falk, Ph.D., has for several years been a member of the staff. In addition to the well known rural, city, and metropolitan health demonstrations conducted by the Fund, there have been numerous studies of public health practice with special reference to the measurement of results to be obtained from public health service. The Fund was a large contributor to the study of the Committee on the Costs of Medical Care and, since the report of this committee, has continued an analysis of the data with special reference to the bearing of these data on sickness insurance. Mr. Kingsbury has been responsible for the publication by the Fund of the Studies on Medical Care in Europe by Sir Arthur Newsholme, and with Sir Arthur, Mr. Kingsbury was co-author of the work, *Red Medicine*.

FRANKLIN H. MARTIN

FRANKLIN H. Martin, M.D., LL.D., D.Sc., D.P.H., distinguished in American medicine as a surgeon, educator, author, and organizer of unusual resourcefulness, died recently in Phoenix, Ariz., at the age of 78.

He was founder of *Surgery, Gynecology and Obstetrics*. Dr. Martin was a member of numerous professional organizations in this country and honorary fellow of medical and surgical societies of several South American countries. In recognition of his services, he received awards from the United States, England, and Italy.

His contributions to medical literature include *Fibroid Tumors of the Uterus*, *Treatise on Gynecology*, and *South America from a Surgeon's Point of View*. He was also author of a monograph, *Australia and New Zealand*. His autobiography was published

under the title, "Joy of Living," in 1933.

FIELDING HUDSON GARRISON

FIELDING HUDSON GARRISON, Colonel U. S. Army, Retired, of Baltimore, Md., most eminent American medical historian, died April 18, 1935, at the age of 64.

Col. Garrison was Assistant Librarian at the Army Medical Library in Washington for 33 years, from 1889 to 1922. He served in the Philippines from 1922 to 1924, and in 1925 he was appointed Consulting Librarian to the New York Academy of Medicine. In 1930 he was appointed Librarian of the Welch Medical Library at the Johns Hopkins University School of Medicine, and also resident lecturer in the history of medicine.

He was co-editor of the *Index Medicus* at the Surgeon General's Library from 1903 to 1912, and editor from 1912 to 1927. His Book *An Outline of Medical History*, is recognized as a classic throughout the civilized world. He was the author also of numerous monographs.—*J.A.M.A.*, 104, 17:1540 (Apr. 27), 1935.

MIDWIFERY PRACTICE IN NEW YORK

FOLLOWING a conference with New York Health Commissioner John L. Rice, Hospital Commissioner S. S. Goldwater announced—the first week of May—the discontinuance of the Bellevue Training School for Midwives.

If the present trend in the reduction of midwife practice continues, it is stated, the proportion of births attended by midwives will amount to less than 2 per cent 10 years from now. In 1934 midwives attended only 5,000 of the 101,239 births in the City of New York, less than 5 per cent, representing a decline since 1914 of 35.3 per cent. The number of midwives licensed to practice in New York City reached a

maximum of 1,799 in 1916, whereas now there are only 700, of whom 30–40 per cent are reported inactive.

TOURISTS IN MEXICO

WHILE in Mexico City recently, J. C. Geiger, M.D., F.A.P.H.A., of the Department of Public Health of San Francisco, made a study of requirements made by the authorities in Mexico of tourists.

He is preparing a program related to the requirements of tourists between the United States and Mexico, which will be submitted for the approval of the health authorities of both countries.

DIABETIC PATIENTS CENSUS

THE New York City Department of Health is making an effort to place all persons with diabetes under the care of licensed physicians, and has for that reason sent a letter to all physicians in the city asking them to inform the department of the number of diabetic patients under their care.

Health Commissioner John L. Rice states that many diabetic patients are using trick diets and harmful nostrums, alleged substitutes for insulin. Information assembled by the New York Diabetes Association indicates that there are as many as 100,000 diabetic persons in the city.

NUTRITION PROJECT IN MICHIGAN

THE Michigan State Emergency Welfare Relief Commission, the Children's Fund of Michigan, and the State Department of Health are coöperating in a program to prevent an increase in scurvy and other dietary deficiency diseases among infants and young children, and to assist in making necessary medical care available for needy prospective mothers. The Michigan branch of the American Academy of Pediatrics is acting in an advisory capacity. Members serve as consultants to work with

the county medical societies and nurses in their respective districts.

The project will continue over a period of 6 months. According to the state medical journal, the work is based on home calls to families on relief or near the borderline in which there are prospective mothers or young children. The expectant mother receives suggestions and, in families with infants, special attention is paid to dietary supervision to guard against scurvy and rickets.

The project was begun at the suggestion of Dr. Thomas B. Cooley, of Detroit, President of the American Academy of Pediatrics. — *J.A.M.A.*, April 27, 1935.

NEW CANCER JOURNAL IN BUDAPEST

ACTA Cancerologica is the title of a new publication dealing with all aspects of cancer. It is published in Budapest and is edited by Dr. Gereb, assisted by Professor Ferdinand Blumenthal, now director of the Cancer Institute in Belgrade. Papers will be published in German, French, and English.

NEW JOURNAL ON IMMUNOLOGY

THE first issue of the *Revue d'immunologie*, Paris, appeared in January, 1935. The editors, all well known in the field of immunology, are Professors Robert Debré, G. Ramon, and Pasteur Vallery-Radot, the grandson of Louis Pasteur.

NEW HEALTH DISTRICT IN NEW YORK

ANEW health district has been established in Tompkins County, N. Y., with headquarters at Ithaca, as a coöperative project of the U. S. Public Health Service, the New York State Department of Health, and the Tompkins County Development Association.

Dr. Vivian A. Van Volkenburgh,

F.A.P.H.A., formerly associate in epidemiology at Johns Hopkins University School of Hygiene and Public Health, Baltimore, Md., is head of the staff.

The new district is the first to be developed under the plan for federal aid to rural areas for health work. — *J.A.M.A.*, April 27, 1935.

PUBLIC RESPONSIBILITY FOR PUBLIC AND PERSONAL HEALTH

AN integrated plan of public health, public medical service and private practice was urged as preferable to health insurance for New York State by Thomas Parran, Jr., M.D., State Commissioner of Health, in the 1935 Biggs Memorial Lecture delivered on May 2 at the New York Academy of Medicine. The thesis of Dr. Parran's talk was the health center plan devised by Dr. Biggs and urged by him upon several sessions of the Legislature from 1919 until his death. This plan contemplated a public medical and health service to be administered by local health departments under state supervision and aid, combined with an improved, private practice in a logical system for all citizens in need of such service. Some of the major points of the lecture are summarized below:

For a sizable proportion of the population, socialized medical care is an accomplished fact, but much of it is at the expense of the doctor and therefore less equitable than when financed by public taxes. . . .

A united attack by private physicians and public health authorities should be made against the catastrophic and chronic diseases of the poorly-paid employed classes who far outnumber in the population the one-seventh now on relief. The majority of these persons are able and willing to bear the cost of private medical care for illnesses which can be treated at home or in the doctor's office. . . .

The whole effort for human betterment has been handicapped because in this nation medicine is not now a vital force in the councils of government. Through the integration and union of needed preventive and curative medical efforts and through the pro-

vision of public medical care, as a matter of right and not of charity for those in need of it, medicine can assume its rightful position of leadership in humanizing society.

The most vocal members of the medical profession up to now, however, have been filled with the fighting spirit of the guilds and trade unions. They have been concerned primarily with protecting the *status quo* and in opposing so-called inroads upon their traditional prerogatives. But the rank and file of medical men have quietly and patiently been carrying the load of unpaid service for their unfortunate fellow men. They could do this easily enough when medical charity was required for no more than 2 per cent of the average practice. Now, unfortunately, many a formerly prosperous doctor has been almost overwhelmed by the need for free service among his patients. Yet still these unsung heroes of medicine have carried on. . . .

The groups needing public care for costly illness might be defined as including all manual laborers and their families, all persons participating in the proposed old age annuity plan or unemployment insurance and all others having an annual income of less than \$2,500. In determining the diseases and conditions which should be cared for at public expense, consideration must be given to the cost of treatment and the extent to which the particular disease or condition is "endowed with a public interest." The types of medical care which should be provided at public expense in whole or in part for the lower economic groups of the population he outlined as: facilities for accurate diagnosis, obstetrical care, hospital care, home nursing and treatment of chronic diseases. . . .

To provide an adequate and decent medical service to our public charges and to extend to the low-income group treatment for the catastrophic and chronic illnesses requiring costly diagnosis and long hospitalization is a necessary public health obligation. "I believe that in the long range it will be financially profitable, through the lightening of our ever-growing load of unemployables. And, I believe that Dr. Biggs would stir anew to the spirit of his thesis of 1882—'There are other considerations far higher than the financial which render government action in regard to the public health imperative.'"

Dr. Parran stated that, in his opinion, it would be desirable to unify under health departments, state and local, medical functions now performed by welfare officers.

Biggs had an orderly and logical mind. These qualities tempered his idealism and his professional vision. "Think things through" was his motto. No one before or since his time has combined with such idealism so practical a program for meeting the public health and medical needs of his state. Had his program of 1920 been adopted in New York State and carried out in the several communities, we should have today no such serious problems in medical care and medical economics as now confront us.—

Health News, New York State Dept. of Health, 12, 19 (May 13), 1935.

PERSONALS

GEORGE S. KELLEY, of New York, was awarded a certificate of merit "for reducing the dangers of silicosis, the dust hazard," at the Franklin Institute Meeting held in Philadelphia on May 16.

DR. DOYLE W. FULMER, of Little Rock, Ark., has been appointed Director of the Saline County Health Unit, succeeding Dr. Cad A. Henry, resigned.

LAWRENCE JACKSON SMITH, M.D., of Apponaug, R. I., is the newly appointed Health Officer of Springfield, Mass. It is announced that Springfield's health department will now be supervised by a public health council, in place of the former board of health.

DR. EDWIN HENRY SCHORER, of Kansas City, Mo., member A.P.H.A., has been appointed Health Commissioner of Kansas City, succeeding the late Jabez N. Jackson.

ALBERT GRANT FLEMING, M.D., of Montreal, Que., Life Member A.P.H.A., has been appointed secretary to the Health Insurance Committee of the British Columbia College of Physicians and Surgeons.

DR. JAMES H. SHRADER, F.A.P.H.A., formerly with the Research Laboratories of National Dairy Products Corporation, Inc., Baltimore, Md., has been transferred to the Sealtest

System Laboratories, Inc., with offices at 120 Broadway, New York. DR. ANNE L. BRADY has been appointed City Health Officer of Ross, Calif., to succeed Dr. George H. Willcutt. DR. CLARENCE E. SIMONDS has been appointed Health Officer of Windham, Conn., succeeding the late Dr. Frederick E. Wilcox.

DEATHS

DR. REUBEN HAYES IRISH, of Troy, N. Y., medical diagnostician and tuberculosis specialist, died of a heart attack April 30, while engaged in clinical work at a public school. He was a member of the board of managers of Pawling Sanitarium and of the staffs of the Leonard and Samaritan Hospitals, of Troy.

DR. JOSEPH HENSCHEL, president of the Bronx Borough Medical Society and a trustee of the New York Physical Therapy Society, died May 1 while delivering a lecture on physical therapy at the New York Academy of Medicine. He was a director of physical therapy at the Bronx Hospital and at St. Elizabeth's Hospital, of New York.

WILLIAM FOWKE RAVENEL PHILLIPS, of Washington, D. C., died February 16.

CONFERENCES

June 2-6, American Federation of Organizations for the Hard of Hearing, Cincinnati, Ohio.

June 3-5, Twenty-Fourth Annual Meeting, Canadian Public Health Association, in conjunction with the Ontario Health Officers' Association, Canadian Tuberculosis Association, and Canadian Social Hygiene Council. Royal York Hotel, Toronto.

Significant Aspects of a Recent Official Survey Concerning the Household Use of Milk in Philadelphia

SENECA EGBERT, M.D., F.A.P.H.A.

*Professor Emeritus of Hygiene and Sanitation, University of Pennsylvania,
Philadelphia, Pa.*

A COMPREHENSIVE study of the household consumption of fluid milk and other dairy products in Philadelphia and its vicinity was made during the summer of 1934 by the Department of Agricultural Economics of the Pennsylvania State College and the U. S. Department of Agriculture. In the same area similar surveys were made in 1924 and 1929.

The field work was done from June 11 to 28, during which time 21 enumerators—college students in economics—obtained direct records from 3,004 families residing in the city, and from 409 in the suburbs. In the city the families lived in 149 separate areas throughout the city. Approximately every 12th home in each area was visited.

The areas from which approximately every 12th family was selected for this survey were the same as those used as a basis for numerous sociological studies by the Department of Industrial Research of the University of Pennsylvania, and this "sample" of the population "has been very carefully checked

periodically by the university and found to be representative of the city in respect to nationality, income, geographical location, ages, social and other conditions, and contains approximately 36,000 families." Consequently, it is believed to be thoroughly representative of the population of the city as a whole, as are the corresponding suburban selections representative of their respective communities. In other words, the study is as nearly as possible in accord with the population and more important, social characteristics of Philadelphia and its immediate suburbs.

The enumerators used printed blanks, having demonstrated their thorough understanding of them and of a detailed set of instructions, were paid on an hourly basis, and were not required to obtain or submit a stated number of records daily. Also, "in order to check the accuracy of the purchases reported by the consumers, records of actual sales by dealers to these families during the same week were checked against amounts reported by the 1,412 individual families. Checks were also made

to find whether or not the families interviewed were receiving milk from any relief agency."

The data concerning the home consumption of milk, butter, and other dairy products were obtained from housewives in most instances, and the information, except where specifically noted, is given in the report just as it was given to the enumerators by those interviewed. The survey had only to do with the quantity of milk and its products bought for home consumption, and did not consider the amounts used in school lunches, at restaurants, or elsewhere by members of the reporting families, or that used in bakeries, ice cream factories, or in other processes outside the home.

STUDY OF DATA OBTAINED

There was a drop in the daily average use of fluid milk per capita in the home since the survey of 1929, when the average was slightly more than 2/3 pint (0.68), to 6/10 pt., a reduction of over 11 per cent in 5 years. It is unlikely that the decline was as marked as this, even though a lessening in the home use of milk was to be expected because of the "depression." A number of factors in the 2 studies have not remained fixed. The marked exodus from the city to suburbs in recent years, largely made up of the native white, Irish, and North European classes, which, according to the survey, use milk and its products more abundantly than most others, has had an influence in lowering the general average and in increasing the disparity between that of the city and suburban residents.

For those families reporting purchase and use, the average weekly consumption was 10.6 qt. of fluid milk, 2.17 lb. of butter and 1.31 qt. of ice cream—an average per capita consumption weekly of 2.25 qt. of fluid or fresh milk, and a little less than 5 oz. of butter and a little more than 1/2 pt. of ice cream.

These quantities as representative of the weekly *average* per capita use by the public generally would be hard to credit, did we not remember that they only indicate the purchase for *home* use. We learn that but 92.3 per cent of the families interviewed purchased fluid milk, and only 92.7 per cent of them bought butter. Almost one-half of the families bought some condensed or evaporated (canned) milk, and almost 40 per cent purchased ice cream.

Similar information was secured regarding the consumption of buttermilk, cream, canned milk (evaporated and condensed), and cheese, both as to the weekly purchase and the per capita use of each. This information is well analyzed and deserves more extended consideration than can be given here. Any student of dietetics or household economics will find this part of the report of interest and value.

NATIONALITY AND OTHER FACTORS

Of those using fluid milk, the highest weekly average per capita was by the Jewish families (2.56 qt.), closely approximated by the native white and Irish (2.53), and the North European (2.34). The lowest average consumption was by the Negro (1.57) and the Mediterranean (1.81) families, this difference being more marked in the case of the Negroes, since only 87 per cent of their families used any fluid milk at home, as compared with 98 per cent of the Jewish and 95 per cent of the native whites. The Negro and Mediterranean groups also showed the lowest average in the use of canned milk and of butter; but the general and free use of olive oil by the South Europeans doubtless accounts for their low average in the case of butter.

According to the averages, the use of fluid milk in the home increased with the per capita income until the latter is about \$18 per week. As it rose above this there was a slight decline in the

quantity consumed, which may be explained by the tendency of those households with larger incomes to make use of a more varied dietary, and also for some members of the family to take more of their meals away from home. Thus, of the 289 families receiving milk from relief agencies and comprising nearly 8.5 per cent of all interviewed, the average weekly consumption of milk per person was 2.12 qt., which was higher than the purchases by families in the lower income groups who were not on relief.

After the average per capita income of the family became \$10 or \$12 per week the personal use of milk in the home varied from 2.64 to 2.84 qt. per week. In the lower income groups the use of fluid milk was definitely related to the size of the family, the per capita average being decidedly less in the larger families, but when the average individual income was \$10 or more, this relationship between the size of family and per capita consumption was not apparent. Perhaps this was because, as a rule, there are not so many children in the families of the higher income groups, and also the use of milk is not so limited to the younger or privileged members of the household—this latter factor being, irrespective of the general rule that the more children in the home the greater the use of milk.

The use of butter increased with the average income per capita, which had a marked effect upon the amount consumed by the family. This is shown by the difference between 0.32 lb. per person for those with the lowest income and 0.84 lb. for those with the highest. Butter was more largely used by the native white part of the population than by others, but with similar small incomes, there was a decided tendency for the large families to consume less butter per capita than the small ones. As the incomes became larger, however, this tendency was not apparent.

The use of condensed or evaporated milk declined when the average personal income reached \$12 per week and continued to do so until it approximated \$18. Of the reasons given for using condensed or evaporated milk, 37 per cent dealt with the price, 30 per cent with convenience of its use, and 18 per cent with the fact that the user liked "canned milk." Seventy per cent of the families purchasing canned milk used it only in coffee; 7 per cent for cooking, and 23 per cent both in coffee and for cooking. It is significant that among the users of canned milk only 7 per cent purchased cream compared with 23 per cent of the families not using canned milk. There was no large variation in its use among the various nationalities, though the North Europeans and native whites were the largest consumers. The size of income did not affect the purchase of canned milk as much as it did that of butter or fluid milk.

ANALYSIS OF REASONS GIVEN FOR USE OF MILK

Eighteen per cent of the reasons given by adults for drinking milk had to do with its health value, and 5 per cent because of doctors' orders, but 75 per cent of the reasons related to liking it. On the other hand, of the reasons given by adults for not drinking milk, 49 per cent were because of a dislike for it, 33 per cent because it cost too much, and 9 per cent because it was thought to be too fattening.

For children, according to the adults interviewed, 2 per cent of the reasons for their use of milk related to physicians' orders, 34 per cent to its health value, and 62 per cent because it was liked—this, for those using it. About one-half of the reasons given for children not drinking milk was because of dislike for it, and 44 per cent because it cost too much.

Of more interest from the public

health standpoint, it was learned that between 80 and 90 per cent of the children between the ages of 1 and 10 years drank milk regularly; at from 9 to 10 years of age there was a decline; and from 9 to 11 years, apparently there was a decline in the percentage who drank milk habitually and a corresponding increase in the percentage that never drank milk.

Fewer mothers drank milk regularly than did any other adult members of the family, the proportion being 17 per cent of mothers, 23 per cent of the fathers, and 36 per cent of the other adults. Moreover, 58 per cent of the mothers as against 52 per cent of the fathers and 40 per cent of the other adults never drank fluid or fresh milk. This is probably because of the customary self-denial of mothers when funds are limited, and because the average per capita income of the family decidedly influences the milk drinking habits. It is serious, nevertheless, because so much depends upon the mother's maintained health and stamina, not only for her own welfare, but also for the good and safety of the children already here and those yet to be born.

In this connection the following quotations from the report are significant:

Generally speaking, the number of people who regularly drink milk has continued to increase during the last 10 years. With the exception of the Italian families, the children up to 13 years of age showed a decided increase in the number drinking milk over the 1929 study. The most phenomenal increase was among the colored children—30 more in each 100 drinking milk every day than 5 years ago. . . . Compared with 5 years ago, 23 per cent more children in the adolescent stage drank milk regularly, but in the Negro and Italian groups there was a decline in the percentage of children between 13 and 18 years of age who drank milk as compared with 1929. . . . Without exception, in the adult group there were fewer people drinking milk regularly than were reported 5 years ago. . . . It is significant that in the nationalities with the highest average per capita con-

sumption of fluid milk there was a high percentage of people drinking milk regularly. . . . A relationship between publicity and increased milk consumption seems clear, but it cannot be concluded that it is a "cause and effect" relationship. The causal relationship may run from high consumption to knowledge of publicity, rather than from publicity to increased consumption.

The statement that over 23 per cent more of the children in the adolescent stage drink milk regularly now than in 1929 is important, especially as it only refers to milk used at home. This naturally directs our attention to schools, although the influence of mothers' meetings, women's clubs and journals, etc., upon the parents must not be overlooked or ignored.

As for the schools, we find in them today not only a direct teaching of the importance and value of milk in the making of sound and healthy bodies, but also that the school lunch is becoming a feature of constantly increasing moment in the life of the child. Milk is stressed as an important part of that lunch, either in its fluid state or as a part of many of the other foods served that children like and naturally choose without much urging, such as cocoa, junket, ice cream, etc., and this applies to many of the boys and girls above 12 or 13 years of age who are shown to average a lower consumption of milk at home than the younger children, for in getting milk in some form of drink or food at school they may forego or decrease its use at home. An investigation as to the total quantity of fresh milk supplied regularly to the many hundreds of public, parochial, and private schools would be instructive and would doubtless show a considerable increase to be added to the per capita average of milk consumed by the children concerned.

Again, it would be interesting to know how many or what proportion of the older members of the families interviewed, including the youths and older

girls no longer at school, are absent from home for a considerable portion of the day either habitually or so frequently that they average at least 5 or 6 meals weekly taken away from home and not prepared for by the home keeper and family provider. Anyone conversant with the multitude of restaurants, cafeterias, etc., in the business sections of a city must marvel at the great quantity of foods necessary to supply the need, among which milk forms a component and considerable part. This, if it could be determined or even approximately estimated, would doubtless increase the per capita average in those families reporting adults or others who never drink milk at home.

Furthermore, the large quantities of fresh milk that are used in bread and cake bakeries, and candy factories, and in the preparation of many kinds of marketed foods need only be mentioned to indicate that, thorough and excellent as the survey in question has been as to the home use of milk, the latter demand is only one of several factors that influence the size of the stream that must unflinching flow in full quantity and unimpaired quality to supply the daily needs of a great community. It would be desirable that a future study, equally thorough in its method, be made of the consumption outside of the home. It is because of this inquiry into and subsequent concentration upon the home use of the milk that the city's daily supply may be and probably will be brought back to what it was a few years ago, and increased to the larger supply point that is advisable in order adequately to maintain the health and welfare of the community.

An appreciation of the total amount of fluid milk regularly distributed in a metropolitan area such as Philadelphia, may aid in comprehending the magnitude and complexity of the problems incident to a city's milk supply. Five years ago in Philadelphia this amount

exceeded 800,000 qt. daily. In recent years it has been somewhat less than this, but has probably not been less than 700,000 qt. a day at any time. Even at its maximum the amount is entirely inadequate for the city's health needs when apportioned to the population according to the well established and well recognized opinions of the best dietetic authorities. Under the rule of a quart of milk for every child and a pint for every adult each day, the supply would have to be increased to well over a million quarts daily, almost doubling the minimum of any time within the last 5 years.

The attainment of such an ideal may seem visionary, but we should work toward the end especially that the 13 per cent of children under 12 years, the 30 per cent of adolescents between 12 and 18, and the 83 per cent of mothers who only occasionally or never drink milk should have their essential and adequate quota.

CONSUMERS SHOW LACK OF ADEQUATE INFORMATION

Each person interviewed was asked if she knew the difference between Grade A and Grade B milk. The majority of the differences as stated by the consumers dealt with the quality of the product. Of the families interviewed using B milk, 26 per cent did not know the difference between A and B milk, and 9 per cent stated that "there was no difference." Approximately half of the differences reported by the consumers dealt with the fact that A was of higher quality than B. Apparently there is not a clear distinction in the minds of consumers between the various grades of milk sold in the Philadelphia market.

Of special interest is the following:

Each person interviewed was asked how much per quart he or she paid for milk. The purpose of this question was to find if the consumer really knew the unit price of fluid

milk. Approximately 47 per cent of the persons interviewed who purchased grade A milk named the retail price that was set by the Pennsylvania Milk Control Board for the Philadelphia market; 35 per cent named a price other than that set by the board. This may be accounted for in 3 ways: first, the consumer may not have known the grade of milk purchased; second, there may have been price cutting in the market; third, the consumer did not know the price paid for A milk. Approximately 18 per cent of the people interviewed stated specifically that they did not know the price they paid.

Approximately 76 per cent of the consumers purchasing grade B milk stated the price for that grade named by the Pennsylvania Milk Control Board. Approximately 13 per cent named a price other than the retail price fixed by the Board, and the remaining 12 per cent stated specifically that they did not know how much per quart they paid. Over 90 per cent of all the consumers interviewed did not know the retail price of cream. Of those purchasing cream, approximately 70 per cent did not know the price they paid.

Undoubtedly the "depression" has had much to do with and is a major reason for the lessened demand for milk. Many families formerly fairly well-to-do have had to economize to the utmost, and far too many have had to become recipients of outside relief, public or otherwise, but the depression has been blamed for much that has been really due to evasion of personal responsibility and duty, or to careless or shiftless thinking. There could be no better illustration of this than in the 22 per cent decrease in the use of milk which occurred within 2 weeks among over 31,000 of the 44,000 Philadelphia families on relief, when relief methods were changed in November, 1934, from food orders to cash relief. By the following month the decrease in the purchase of fluid milk was as great as 29.6 per cent.

Milk is not the only necessity of which the use has been unduly curtailed, but as regards family and personal health, it is perhaps the most important. Aside from the direct influence of the depression upon the dietaries and nu-

trition of families actually affected by it, the next and most serious factor in causing families and individuals to lessen instead of increase their use of milk and its products as a necessary part of the diet is the propaganda that the cost of milk to the consumer is too high in view of the price paid to the producers.

MUNICIPAL STANDARDS A SAFEGUARD

It will be well to recall and re-state certain matters concerning Philadelphia's milk supply, past and present, although space will not permit a thorough discussion of them and what they have meant in affecting and influencing the health and lives of the population.

In 1913 an ordinance was adopted that required the pasteurization of all fluid milk sold in the city for direct consumption, except that which was produced under such conditions and professional inspection as would justify its sale as "certified" or "inspected raw milk." Since then there have been other ordinances and regulations requiring the periodical inspection by city officials of all pasteurizing and distributing plants, of the sale of milk only from tuberculin tested cows, etc., etc., with the result that of all milk sold in the city for direct use in 1932, 99.53 per cent was pasteurized and less than $\frac{1}{2}$ per cent was sold as "certified" or "inspected raw milk."

In 1912 there were approximately 2,500 milk dealers or distributors in the city; now there are about 90. In that period there were thousands of cases of typhoid fever with over 200 deaths per annum. Even so, the cases and deaths had been much reduced within the preceding 5 years by the completion of the city filters and the supplying of clean water to the whole community. In 1913 the number of deaths from typhoid fever showed a marked increase and the mortality rate from infantile diarrhea was high; hence a pasteurizing

ordinance for milk and subsequent regulations governing its production and care. Since the mortality due to the diseases mentioned, and others of like nature, has progressively decreased until in 1934 there were only 18 deaths from typhoid fever and 146 deaths of children under 1 year from infantile diarrhea in the city, with milk certainly being a very improbable factor in causing any of them, and not a single milk-borne epidemic in Philadelphia since 1916.

To increase the use of milk to a total more nearly adequate for the community will require much persistent effort and the best thought of all concerned in the public welfare and, especially, in the nutrition and welfare of children now and as future citizens.

For a long time to come the best results in developing the extended and greater personal use of milk and its products will probably come from continuous and wisely directed publicity of all legitimate kinds and by all concerned in advancing human welfare. This has been effective in the recent past and throughout the depression, and is shown by the increase in the number of school children regularly drinking milk. Too much credit cannot be given to every organization and agency that has had a part in the splendid educational work already done, and in aiding them and others to continue and increase the efforts they have made. The methods of the city health departments, the American Child Health Association, the Dairy Council and others should have more than passing commendation. Still more

intensive efforts must be made, especially among parents and other adults, to bring home to them that milk is not only an important and healthful food but that it gives value more than any other staple one of similar cost and that it is cheap only in the sense of price.

The following editorial in a recent number of the *Journal of the American Medical Association* indicates that this need is not a local one or peculiar only to Philadelphia and its neighborhood:

The unique importance of milk in the dietary has been fully established by investigators in nutrition during the past 30 years. Largely through the studies of Sherman and his cogent presentation of the results, there has been given to the human requirement for milk a quantitative expression. A quart of milk daily per child has become a by-word with practical workers in nutrition. How does the current per capita consumption compare with this standard or one based on it? Assuming that adults require less milk than children and that other suitable foods can be substituted in part for milk, the *Consumers Guide* states that a minimum-cost diet should provide 260 quarts of milk or its equivalent annually. "What we are actually getting is about 191 quarts per person a year—and this is an average, which means that a lot of people are getting very much less." Similar evidence is provided by the statistics issued by the Department of Agriculture. In 1933 the daily per capita consumption of milk and cream in cities and villages was about 154 quarts. Thus there is considerable discrepancy between the current consumption of milk and what it ought to be according to conservative expert opinion.

Culture Media Used for Routine Diphtheria Cultures With a Suggested Modification of Loeffler's Blood Serum Medium*

ROSS L. LAYBOURN, F.A.P.H.A.

Bacteriologist in Charge, Public Health Laboratory, Kansas State Board of Health, Topeka, Kans.

WHILE the range of reaction in which *C. diphtheriae* will grow on artificial culture media is quite wide, the effect of different reactions within this range on luxuriance of growth, morphology, and staining is marked. The following references illustrate these points:

Medalia¹ found that a change of pH 0.4 in the better growth range had a marked influence on the luxuriance of growth of the organism.

There is usually little change in morphology between pH 7.8 and pH 6.4, but beyond this zone decided differences are noticed. The author² has found that many of the Wesbrook types can be produced from a culture which normally shows a predominance of Type C by varying the reaction of the medium. Plates I and II show the same strain grown on medium of pH 7.4 with Wesbrook Type C predominating, and on the same with a pH 6.1 with Types C-2 and D-2 predominating.

Stovall³ reported in 1923 that the morphology and staining characteristics of *C. diphtheriae* in throat cultures con-

taining *S. aureus* were quite different and less typical than the characteristics of the same strain when grown in pure culture. In view of the effect of reaction upon the morphology of this organism, it seemed probable that the variations observed by Stovall might be due to the production of acid by *S. aureus* from the dextrose in Loeffler's blood serum. This assumption was confirmed by a preliminary study of 5 strains of *S. aureus* isolated from throat cultures which changed the reaction of tubes of a modified Loeffler's blood serum from an initial pH of 7.1 to a pH of 6.0 to 5.8 in 18 to 24 hours.

Considerable emphasis is frequently placed on morphology and staining in the examination of diphtheria throat cultures, particularly by inexperienced workers, and it seems desirable that the media used should be of a composition and reaction which would support luxuriant growth and permit the development of what are termed "typical forms" of *C. diphtheriae*, if for no other reason than to facilitate the examination of cultures. Such a medium must either be well buffered and hold the reaction in the vicinity of the optimum for *C. diphtheriae* (pH 7.4-7.6)

* Read before the Laboratory Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 6, 1934.

in the event of considerable acid production by other organisms present, or the fermentable carbohydrate content must be reduced to limit acid production. A study of this problem conducted along these lines has been divided into the following sections: (A) changes in reaction occurring during the storage of uncoagulated serum and serum bouillon mixtures; (B) the effect of reaction upon the appearance and physical properties of coagulated serum; (C) changes in the reaction of serum-bouillon mixtures during sterilization and the buffer effect of different media; (D) the production of acid from coagulated serum media by *S. aureus*; (E) an improved medium for diphtheria throat cultures.

METHODS

Determination of reaction of serum-bouillon mixtures and coagulated serum media—Colorimetric hydrogen ion determination on serum-bouillon mixtures and coagulated serum media presents many difficulties including the accurate comparison of colors in serum, the determination of the reaction of coagulated serum medium, and the protein

and salt-effect errors introduced by the composition of the test substance. A commercial colorimetric hydrogen ion set designed for use with small amounts of biological fluids was used. This employs small glass cells about 10 mm. inside diameter and 5 mm. inside depth, and readings are made on an opal glass plate. The principle of dilution of the specimen with neutral distilled water, suggested by Brown,⁴ was employed to reduce the color of the serum, 1 drop of the test substance being diluted with 5 drops of neutral distilled water. Two drops of the indicator were added to both the test cell and those containing the standard buffer mixtures. Dilution was also found materially to reduce protein and salt-effect errors, and bromthymol blue was found to be the most satisfactory indicator as regards range and protein and salt-effect errors.

Readings on coagulated medium were made on the water of condensation and were found to give quite an accurate index of the reaction of the coagulum.

In establishing the reliability of the method, electrometric determinations were made using the quinhydrone elec-

PLATE I—*C. diphtheriae*, culture No. 663, after 18 hours' incubation on Loeffler's medium of an initial reaction of pH 7.4. Granular types predominating.

PLATE II—*C. diphtheriae*, culture No. 663, after 18 hours' incubation on Loeffler's medium of an initial reaction of pH 6.1. Solid staining types predominating.

trode designed by Cullen⁵ for determining the reaction of small amount of blood serum. Comparisons were made between the water of condensation and the coagulated medium by pushing the Cullen electrode, less its capillary tube, into the coagulum and connecting to the calomel electrode by means of a salt bridge consisting of a glass tube containing saturated potassium chloride solution in 3 per cent agar which was pushed into the coagulum.

While the colorimetric method used would hardly be termed one of great precision, it was found to be sufficiently accurate for the problem. In most instances the error did not exceed pH 0.1 rarely pH 0.2. The larger errors usually occurred in the extreme range of the indicators.

Sera used—Beef, sheep, horse, hog, and human sera, the latter being the pooled surplus of inactivated Wassermann specimens. All sera used were preserved with chloroform and stored from 1 to 2 weeks.

Formulae used—While trial lots of media were made, eliminating various constituents, the following basic formulae were used in this investigation.

Other formulae were tried in which the proportion of serum was increased to 90 per cent. Lots of media were also made up with a content of peptone, dipotassium phosphate and other substances approximating the concentrations used in infusion media. Such formulae were found to be too concentrated for luxuriant growth and are not reported in this paper.

Stains used—Loeffler's alkaline methylene blue and the author's⁶ diphtheria stain have been used in these studies.

CHANGES OCCURRING IN SERUM AND SERUM-BOUILLON MIXTURES DURING STORAGE

The practice of obtaining serum in large quantities and preserving it with

chloroform until needed is followed in some laboratories which use large quantities of Loeffler's blood serum. While bacterial action is inhibited by the chloroform, it does not entirely arrest enzyme action. Changes take place rather slowly but when serum so preserved is stored at room temperature from 2 to 6 weeks, considerable change in reaction will frequently be observed. Beef sera preserved in this manner and stored for considerable lengths of time have been found to give reactions varying from pH 6.2 to pH 7.4. The drift in reaction during storage is usually toward an increased acidity. Because of this fact, a formula which calls for the use of a certain serum to which a fixed amount of sodium hydroxide solution is added, cannot always be expected to give uniform results when made with preserved serum.

BASIC FORMULAE USED

Formula I (Loeffler's)

Serum	3 parts
0.5% dextrose, meat extract bouillon	1 part

Formula II

Serum	800 c.c.
Glycerol	40 c.c.
Bouillon concentrate	160 c.c.

Bouillon concentrate

Proteose peptone, Difco	1.25 gm.
Dextrose	3.00 gm.
Dipotassium phosphate	1.25 gm.
Water	160 c.c.

Dissolve with heat.

Formula III

Serum	800 c.c.
Glycerol	40 c.c.
Bouillon concentrate	160 c.c.

Bouillon concentrate

Proteose peptone, Difco	1.25 gm.
Dipotassium phosphate	1.25 gm.
Cystine	0.5 gm.
Water	160 c.c.

Dissolve with heat.

NOTE: Not all the cystine can be dissolved in this amount of water. Undissolved cystine should be in suspension in the concentrate when added to the serum.

THE EFFECT OF CHANGE OF REACTION
UPON THE APPEARANCE AND PHYSICAL
PROPERTIES OF COAGULATED
SERUM MEDIA

The consistency, color, and adherence to the culture tube of coagulated serum media is indicative of the reaction of the medium. Media which are acid in reaction are chalk-white and adhere tenaciously to the tube. Very acid media usually contain irregularly shaped bubbles and crumble under the pressure of the swab during inoculation. The chalk-white media sometimes supplied commercially, while pleasing in appearance, advertises by that appearance that it is too acid for best results.

The addition of sodium hydroxide solution to serum media causes a hydrolysis of the serum which is proportional to the amount of the reagent added and color, transparency, consistency, and adherence to the tube change in proportion to the extent of the hydrolysis. While these manifestations of hydrolysis vary somewhat with the sera of different animals, generally speaking, moderate hydrolysis produces an opaque

cream colored coagulum which adheres well to the tube while more extensive hydrolysis results in soft, mushy, semi-transparent coagulum which is either tan or gray-black in color depending upon the kind of serum used. The first manifestation of hydrolysis which makes a coagulum unsatisfactory for throat cultures, particularly when the medium is shipped or transported, is its failure to adhere firmly to the tube. The reaction at which this occurs varies with the sera of different animals and with other constituents of the medium. With medium made according to the standard Loeffler's formula, the most alkaline final reaction at which different sera give a coagulum which adheres firmly to a grease-free tube is as follows:

Serum	pH
Human	7.6-7.8
Hog	7.3-7.5
Horse	7.3-7.4
Sheep	7.1-7.2
Beef	6.7-6.8

The reaction of a coagulated serum medium should be in the vicinity of the optimum for the growth of *C. diphtheriae*, and at the same time, the smallest possible amount of sodium hydroxide solution should be added to avoid excessive hydrolysis. Human and hog serum are, therefore, best adapted to use in the media used for diphtheria cultures. These two sera also give a firmer coagulum at all reactions than horse, sheep, and beef sera.

CHANGES IN THE REACTION OF SERUM-
BOUILLON MEDIUM DURING
STERILIZATION

When the adjustment of the reaction of a serum-bouillon medium has not been attempted, there is no appreciable change in reaction during sterilization, but when the reaction has been adjusted there is a drift of pH 0.1-0.6 toward the original unadjusted reaction on both the acid and alkaline sides during sterilization. The drift is not

^a = Unsatisfactory Consistency

so great in buffered media (Formulae II and III) as it is in Loeffler's medium (Formula I), but it is large enough to require experimentation and checks on the finished product in order to be assured that it has the final reaction desired. Table I gives the reaction of lots of media made from the various kinds of sera used before and after sterilization and the drift in reaction of buffered hog serum medium is presented graphically in Chart I.

The effect of buffering is apparent from a study of Table I. While the final reaction of buffered media of satisfactory consistency does not always approach the optimum reaction of *C. diphtheriae* as closely as that of Loeffler's medium, it is well within the range of typical growth and considerably more acid production is required to change the reaction to the point where the morphology of the organism is noticeably influenced, than is required to produce the same effect in standard Loeffler's medium.

PRODUCTION OF ACID IN COAGULATED SERUM MEDIA BY *S. AUREUS*

In studying the production of acid by *S. aureus* lots of hog serum medium having a reaction of pH 7.2 after sterilization were prepared, according to Loeffler's formula, which contained respectively 0.25 per cent and 0.125 per cent and no dextrose (these amounts of dextrose being the quantity present in the mixture when 1 per cent and 0.5 per cent dextrose, meat extract bouillon are used). Five strains of *S. aureus*, isolated from throat cultures, were grown on 5 or more tubes of each lot of medium and the reaction determined after 18 to 24 hours' incubation. Medium containing 0.25 per cent dextrose had a reaction of pH 5.8, the lot containing 0.125 per cent dextrose of pH 6.0, while that with no dextrose has a reaction of pH 6.6, indicating that the changes in reaction occurring

during the growth of *S. aureus* bear a relation to the amount of dextrose in the medium. The change which took place in the medium to which no dextrose was added may be accounted for by the presence of fermentable carbohydrate in the serum. Since this change is relatively small it may be expected that buffering will reduce it still further.

In connection with the production of acid in diphtheria throat cultures, it is worthy of note that members of the colon group are found with considerable frequency and a few checks made indicate that the change in reaction brought about by this group is even more marked than that produced by *S. aureus*.

IMPROVED MEDIA FOR DIPHTHERIA THROAT CULTURES

C. diphtheriae grows so poorly on standard serum medium from which the dextrose has been eliminated that it was necessary to add other nutritive substances in order to secure luxuriant growth.

Glycerol has been reported by a number of workers as increasing the growth of *C. diphtheriae*, and the author has used it since 1919 with excellent results.

Dipotassium phosphate was originally added to the medium for the purpose of increasing the buffer action, and while the unadjusted reaction of medium containing this salt is slightly more alkaline than that of Loeffler's medium, it also contributes to the luxuriance of growth.

Proteose peptone, Difco, has been used in modified formulae because the buffer effect is slightly superior to that of standard peptone.

Gibbs and Rettger⁷ found that the addition of 0.5 per cent cystine to sugar free, veal infusion produced a heavy typical growth, and Braun and Mundel⁸ considered it necessary to the oxidation metabolism of the organism.

They also found the addition of cystine to Loeffler's blood serum stimulated the formation of larger colonies.

Beck⁹ reported that when the diphtheria bacillus is grown in an atmosphere of hydrogen sulphide, growth is stimulated and granule formation is increased. The addition of sodium sulphide (sodium monosulphide) achieves the same result and in the writer's opinion is the most important departure from the standard Loeffler's formula incorporated in this report.

The following formula, incorporating these substances gives a more typical and more luxuriant growth of *C. diphtheriae* in mixed throat cultures than Loeffler's blood serum.

Hog or human serum.....	800 c.c.
Glycerol	40 c.c.
Sodium sulphide (sodium monosulphide) dissolved in 10 c.c. of cold water.....	1.50 gm.
Bouillon concentrate	160 c.c.
Bouillon concentrate	
Proteose peptone	1.25 gm.
Dipotassium phosphate	1.25 gm.
Cystine	0.5 gm.
Water	160 c.c.

Dissolve with heat.

NOTE: Not all the cystine will be dissolved in this amount of water. The undissolved portion should be in suspension in the concentrate when it is added to the serum.

When hog serum is used the reaction of the mixture should be adjusted to approximately pH 7.6-7.7 before coagulation. This requires from 5 to 10 c.c. of normal sodium hydroxide solution per liter of the mixture and the sterilized medium will have a final reaction of about pH 7.3. No adjustment of the reaction is necessary in well preserved human serum, obtained by pooling the surplus serum from inactivated Wassermann specimens, which has been stored in a refrigerator. Medium made according to this formula is tan in color, of a firm consistency and adheres well to the culture tube.

PLATE III—*C. diphtheriae*, culture No. 667, and *S. aureus*, culture No. 1341, after 18 hours' incubation on buffered serum to which no dextrose had been added. Initial reaction of the medium pH 7.3. Reaction after 18 hours' growth pH 6.9. Granular types predominating.

PLATE IV—*C. diphtheriae*, culture No. 667, and *S. aureus*, culture No. 1341, after 18 hours' incubation on Loeffler's medium. Initial reaction of medium pH 7.3. Reaction after 18 hours' growth pH 5.8. Solid staining types predominating.

The use of other kinds of sera than those specified will give a product superior to a similar Loeffler's medium, but the reaction cannot be made as alkaline as hog serum medium due to the production of a coagulum of unsatisfactory consistency.

S. aureus growing on hog serum medium, prepared as above, changes the reaction from pH 7.3 to pH 6.9 during 18 to 24 hours' incubation, as compared to pH 5.8–6.0 on Loeffler's medium. This is well within the zone of reaction in which *C. diphtheriae* grows luxuriantly with typical morphology and staining, and comparisons made with mixed cultures of *S. aureus* and *C. diphtheriae* on this medium and on Loeffler's hog serum having a reaction of pH 7.3 show marked differences in morphology and staining. These are illustrated in Plates III and IV, in which the 2 media were inoculated with the same strains of *S. aureus* and *C. diphtheriae* and incubated for 18 hours. Growth on Loeffler's hog serum medium was not so luxuriant as on the buffered medium and the diphtheria bacillus

showed a predominance of solid staining forms while on the buffered medium Wesbrook's Type C predominated.

SUMMARY

1. Changes in reaction occur during the storage of blood serum preserved with chloroform which influences the reaction of coagulated serum media in which such serum is used.

2. The color and consistency of serum-bouillon media are indicative of the reaction. The addition of sodium hydroxide solution to serum-bouillon mixtures causes a hydrolysis which, if extensive, makes the consistency of the coagulum unsatisfactory for use. Human and hog sera require the use of less alkali in the adjustment of the reaction than beef, sheep, and horse sera, and are preferable for this reason. Beef, sheep, and horse sera form a softer coagulum than human and hog sera which also makes them less satisfactory for use in throat culture media.

3. The reaction of bouillon-serum mixtures changes during coagulation and sterilization, and allowance must

be made for drift of reaction in adjusting the uncoagulated mixture.

4. *S. aureus* produces sufficient acid from the dextrose in Loeffler's medium in 18 hours to influence greatly the luxuriance of growth, morphology, and staining of *C. diphtheriae*.

5. A formula for diphtheria culture medium is suggested which supports luxuriant growth of *C. diphtheriae* with typical forms of the organism in the presence of *S. aureus*.

A Federal Hospital for Drug Addicts

THE United States Narcotic Farm at Lexington, Ky., was dedicated the end of May, and opened its doors to narcotic addicts now incarcerated in the various federal prisons. Eventually plans call for the admittance of citizens addicted to the drug habit who voluntarily wish to avail themselves of the newest scientific treatments.

The institution at Lexington is designed primarily for the care of the more intractable type of person, largely the prisoner type. For that reason, the custodial features have been emphasized. The second institution, which will be located at Fort Worth, Tex., will be more open in character, being designed as a cottage type, and the custodial features will be less emphasized.

The main building of the Lexington narcotic farm will accommodate 1,000 persons. In addition there will be quarters for the 250 people required to

operate the institution with an annual pay roll of approximately \$340,000.

Structures on the farm include a complete dairy, poultry house, greenhouse, abattoir, root cellar, and other buildings necessary for the operation of farm activities.

Shops have been established to afford occupation, vocational training and education. Experiments are to be carried out in laboratories to determine the best methods of treatment and research in this field and the results disseminated to the medical profession and the general public. . . . In the laboratories of the Public Health Service, researches are now being made to determine which particular part of opium probably will not cause addiction but will give the beneficial results of opium.—*The United States News*, May 27, 1935.

An Outbreak of Milk-Borne Hemolytic Streptococcic Infection

ARTHUR W. NEWITT, M.D., JEAN W. GLASSEN,
AND R. W. PRYER, DR.P.H., F.A.P.H.A.

Michigan Department of Health, Lansing, Mich.

DURING September, 1934, the attention of the Michigan Department of Health was called to a large number of cases of severe sore throat in the village of Petersburg, a residential and farming community in the west-central part of Monroe County, with a population of about 700.

A number of cases were visited and the similarity of symptoms was strikingly evident. The typical case appeared acutely ill. The face was flushed and the eyes were watery and slightly injected. The mucous membrane of the mouth was red, and the tonsils, soft palate, and uvula were injected and edematous. The anterior and posterior cervical lymph nodes were considerably swollen with usually more enlargement on one side. Several patients had so much swelling of the neck that the muscles were rigid and any movement caused severe pain. Attending physicians reported that frequently the swelling would subside on one side only

to appear on the other. Some of the patients had a skin eruption which resembled that of scarlet fever, but was darker, blotchy, and unevenly distributed. The disease more nearly resembled septic sore throat than scarlet fever.

Milk consumed in Petersburg was supplied by one dairy (hereinafter designated "G" dairy), and by a number of persons owning one or two cows. None of the milk was pasteurized. All patients visited were users of "G" milk. A hasty survey of 20 families where "G" milk was not used disclosed no cases of sore throat.

Samples of milk were collected from each cow at the "G" dairy, each sample being a pooled specimen from the four quarters. There were 18 milking cows in the herd. These milk samples, together with throat swabs from patients ill with the disease, were immediately sent to the Michigan Department of Health Laboratory for culture.

FIGURE I—Percentage of Cases by Date of Onset

After 18 hours the laboratory reported the presence of hemolytic streptococci in the milk obtained from cow No. 7. (This cow had been purchased about 2 months before the outbreak.) It was decided on the strength of the evidence at hand, to order "G" dairy to cease distribution of milk until further notice. This order was issued on the afternoon of September 15. The president of the village made arrangements with an out-of-town distributor to supply the people with pasteurized milk, beginning September 16.

TABLE II
COMPARISON OF CASES AND NON-CASES BY MILK SUPPLY

Milk Supply	Cases		Non-Cases		Total	
	Number	Per Cent	Number	Per Cent	Number	Attack Rate
Exclusively "G" milk.....	138	74.2	220	47.4	358	38.5
Regularly "G" milk.....	21	11.3	38	8.2	59	35.6
Occasionally "G" milk....	16	8.6	58	12.5	74	21.6
Exclusively other milk.....	11	5.9	148	31.9	159	6.9
Total	186	100.0	464	100.0	650	28.6

On September 17 the investigation was resumed. A veterinarian from the State Department of Agriculture examined the herd and, without previous knowledge of the laboratory report, made a diagnosis of mastitis in cow No. 7. Separate specimens of milk were then taken from each quarter of this cow for further bacteriologic examination. The cow was killed and the udder sent to the laboratory. The milk from the right front quarter was grossly pathologic.

On September 24 the Monroe County nurse with the cooperation of the village officials began a house-to-house survey of the entire village to collect

the necessary data for a comprehensive epidemiologic study.*

EPIDEMIOLOGY

Analysis of the data obtained in the survey shows that of 650 persons whose histories were obtained, 186 (28.6 per cent) had had sore throat between August 28 and September 26. Referring to Figures I and II, it may be seen that the 8 day period, September 3 to 10, was the time of greatest incidence, in spite of the fact that distribution of milk from "G" dairy was

* The authors gratefully acknowledge the valuable service of Catherine Connelly in making the survey to obtain epidemiologic data.

FIGURE III—Attack Rate According to 5 Year Age Groups

not discontinued until September 15. The possibility of the milk conveying the infection was early suspected by physicians and some of the people in the village, and for some time previous to September 15 an unknown number had been boiling the milk before use. Other families had discontinued the "G" milk and were buying elsewhere. Just how much these changes affected the outbreak could not be determined. However, it would seem that the majority of the population using "G" milk (133 or 71.5 per cent by September 10) was infected within a few days; indicating that they were exposed almost simultaneously to a purveyor of infection common to all.

The distribution of cases by milk supply according to date of onset is given in Table I. The distribution of cases indicates that users of "G" milk were more likely to be attacked. However, it should be borne in mind that "G" dairy was the only concern seri-

ously engaged in supplying milk in the village.

Table II shows a comparison of cases and non-cases by milk supply. It is quite evident that the attack rate (38.5 per cent) among those persons using "G" milk exclusively, is much higher than the attack rate (6.9 per cent) among those persons who obtained their milk exclusively from some other source. The difference in these attack rates is statistically significant and shows almost positively that the milk from "G" dairy must have been responsible for the infection. The responsibility of this milk is also indicated by the downward trend of the attack rates according to the probability of exposure to "G" milk.

Secondary cases were few, judging from the limited duration of the outbreak. In this respect the outbreak conforms to the findings in other milk-borne outbreaks of streptococcic infection reported.

Table III is a tabulation of the attack rates according to sex by 5 year age groups. This is graphically shown in Figure III. The attack rate was slightly higher for females than for males, but not significantly so.

A comparison of curves representing the cumulative percentage age distribution of the cases and of the general population is shown in Figure IV. It is evident that the infection showed little selectivity for any specific age group. This observation is emphasized by comparison with the typical age distribution of scarlet fever.

A remarkable feature of the outbreak was the complication of erysipelas which occurred in 5 cases. All had used "G" milk and had the typical symptoms associated with the outbreak. The erysipelas occurred as they were recovering from the throat infection. Two of the cases of erysipelas had had previous attacks. Cross-infection with other erysipelas cases could be almost positively ruled out for the following reasons: (1) All cases occurred in separate households. (2) Each patient had been ill and confined to the house for several days prior to the onset of erysipelas. (3) Two physicians were in attendance on the cases.

Information as to the presence of rash accompanying the sore throat was available for 169 cases. Of these, 49, or 29 per cent, had a skin eruption. It is interesting to note that in a similar

FIGURE IV—Percentage Age Distribution of the Population and Cases of Sore Throat in Petersburg—Also Scarlet Fever Cases in 1932 in Rural Monroe County

outbreak which occurred in Sweden in 1933,¹ 32.4 per cent of the cases had "scarlatina," the remainder had a more or less severe angina.

The toxin produced by the hemolytic streptococcus isolated from the milk and udder and from the throats of patients was neutralized by standard scarlet fever antitoxin. The question arose as to whether or not persons who had had the infection developed immunity to scarlet fever or Dick toxin. Three months after the outbreak, 126 persons were Dick tested. There were 65 persons tested who had had sore throat and of these 54, or 83.1 per cent, were negative. In the control group there were 61 tested of whom 43, or 70.5 per cent, were negative.

In Table IV is a comparison of Dick tests in cases and controls by age

TABLE IV
REACTIONS TO THE DICK TEST

Persons Who Had Sore Throat During the Outbreak				Control Group		
Age	Number Tested	Dick Test Result		Number Tested	Dick Test Result	
		Number Negative	Per Cent Negative		Number Negative	Per Cent Negative
0-9.....	19	14	73.7	13	7	53.8
10-19.....	18	14	77.7	27	17	63.0
Total.....	37	28	75.7	40	24	60.0

groups. All persons who had had scarlet fever previously were eliminated.

Apparently those persons who had had sore throat, had in general the advantage of a higher grade of immunity to Dick toxin than did those in the control group. Nevertheless, the proportion of immunes is considerably less than the 90 per cent found among persons who have recovered from scarlet fever.^{2, 3} Another observation was that of 23 persons who had a scarlatinaform rash when ill with the streptococcic throat infection, 5, or 22 per cent, had a positive reaction to the Dick test. In contrast, of 21 persons who had had scarlet fever before the outbreak, only 1, or 4.8 per cent, showed a positive reaction. (This positive reactor had sore throat during the outbreak.)

Six deaths could be definitely attributed to hemolytic streptococcic infection, a fatality rate of 3.2 per cent. All deaths occurred in persons over 50 years of age, of whom 5 were males and 1 female. Two died from the complication of erysipelas and all were in an impaired state of health prior to the time they acquired the infection.

BACTERIOLOGY

Milk and Udder Cultures—On September 14, 18 specimens of milk from individual cows in "G" dairy were sent to the laboratory. Poured sheep's blood agar plates were made and the cultures examined after 24 and 48 hours' incubation at 37.5° C. Only one of the cultures, the pooled specimen from cow No. 7, showed hemolytic streptococci.

Additional samples from each of the quarters of cow No. 7 were examined. The milk from the right front quarter was yellow and contained some clots. Hemolytic streptococci were recovered from the milk from this quarter only. On September 18 the cow was killed and the udder examined in the laboratory on the same day. The udder was

apparently normal upon surface examination, except for a lump near the base of the teat of the right front quarter. This lump showed some fluctuation on palpation. Each of the quarters was incised and specimens of material were collected aseptically from the lactiferous sinuses. The glandular tissue of the right front quarter was deep yellow. The fluid in the sinus was purulent and contained clots. Sedimentation took place rapidly on standing in a test tube. Smears from the fluid showed many pus cells. Only that culture made from the right front quarter showed hemolytic streptococci.

Throat Cultures—The first throat swabs, 9 in number, were brought to the laboratory on September 14. No hemolytic streptococci were found. On September 15, 22 swabs were received, none of which showed hemolytic streptococci. The routine method of this laboratory was used, namely, each swab was rubbed over a portion of the surface of a sheep's blood agar plate and the culture allowed to incubate over night.

The observation that many colonies had developed from the milk cultures below the surface of the blood agar indicated that perhaps the organism we were seeking grew best at a reduced oxygen tension. It was decided, therefore, to use poured blood agar plates for culturing the remainder of the throat specimens.

On September 18, 46 throat swabs were received. Surface plate cultures were first made. The swabs were then placed in 1 c.c. of dextrose broth and incubated at 37.5° C. for ½ hour. The broth cultures were then mixed with melted blood agar, and pour plates made. Both surface and pour plates were examined after 24 and 48 hours' incubation at 37.5° C. Seven cultures showed hemolytic streptococci in the pour plates, 2 of which showed colonies on the surface also. Two of the cul-

tures were subsequently lost through failure to grow in sub-cultures.

A tabulation of fermentation reactions and other characteristics is given in Table V. All of the cultures isolated except throat culture No. 15, which was not a true beta hemolytic streptococcus, are classified as being of human origin. Fermentation of trehalose but not sorbitol, low acidity in dextrose broth, and lack of hydrolysis of sodium hippurate were used as criteria.

Throat cultures Nos. 13 and 31 corresponded in all respects to those recovered from cow No. 7, except for differences in growth characteristics. The cultures recovered from the milk were always difficult to grow on the surface of blood agar plates while those recovered from the throats grew well after the second or third sub-culture. Difficulty was also encountered in obtaining growth in carbohydrate broths of organisms recovered from the milk, heavy inoculations being necessary.

All cultures were carefully examined for capsules and mucoid colonies, characteristics of *Streptococcus epidemicus*

originally described by Davis⁴ and regarded as the specific causative organism in septic sore throat by Frost *et al.*⁵ None of the cultures showed any tendency toward capsule formation when grown in any medium used, nor when recovered from peritoneal exudate after passage through the mouse. The moist india ink method and Gin's method⁶ were used in the search for encapsulated organisms. One c.c. of dextrose broth culture inoculated intraperitoneally was used for each mouse pathogenicity test.

All the cultures killed mice within 16 hours after inoculation except No. 36 which was found to be non-pathogenic.

SEROLOGY

Toxins produced by cultures of the hemolytic streptococci originally isolated from the throats of patients and from the milk and udder of cow No. 7 were tested for neutralization by standard scarlet fever antitoxin. The protocol covering the titrations is given in Table VI. It will be noted that one unit of antitoxin completely neutralized 1 c.c. of 1:100 dilution of toxin. The

titrations were repeated about 2½ months later (January 7, 1935), with the same results.

The toxin produced by the strain isolated from the cow's udder contained between 20,000 and 50,000 skin test doses per c.c.

Because erysipelas had developed as a complication in 5 of the cases of sore throat, the possibility of neutralization of the toxin produced by the strains with erysipelas antitoxin was considered. Similar dilutions of the toxin were titrated with erysipelas antitoxin produced by Parke Davis and Company, No. 024265 B. However, the erysipelas antitoxin was unable to neutralize the toxin produced by any of the strains from the Petersburg outbreak.

COMMENTS

Clinically, the disease produced by this infection differed materially from

scarlet fever. The differences may be summed up as follows:

1. Only 29 per cent of the cases had a rash, indicating that a predominating quality of the Petersburg strain was the production of disease primarily by tissue invasion, and secondarily by toxin production.

2. There was no selectivity for the younger age groups as is the case with scarlet fever.⁷ This observation agrees with the findings of Godfrey.⁸

3. Erysipelas was a complication of 5 cases in the Petersburg outbreak, whereas this complication is exceedingly rare in scarlet fever cases where cross-infection can be ruled out.*

4. There is some evidence, as demonstrated by the Dick test results, that the degree of immunity following infection with the Petersburg strain was less than might be expected following typical scarlet fever.

In spite of the clinical evidence cited above, the neutralization of the toxin

* Erysipelas occurred as a complication in but 1 of 9,061 cases of scarlet fever in Herman Kiefer Hospital, Detroit.⁹

produced by the Petersburg strain, by scarlet fever antitoxin, cannot be ignored, and it is hoped that future studies will throw more light on the intimate relationship between strains of hemolytic streptococci.

SUMMARY AND CONCLUSIONS

1. There were 186 known cases and 6 deaths in an outbreak of sore throat in Petersburg, Mich., during September, 1934.

2. The attack rate was 28.6 per 100 inhabitants, the fatality rate 3.22 per 100 cases.

3. The outbreak was caused by the transmission, through raw milk, of hemolytic streptococci from one infected quarter of one cow.

4. None of the cultures from the milk nor from the human throats showed the moist, mucoid colony nor the capsule formation characteristic of *Streptococcus epidemicus*.

5. The cow was probably infected by a hemolytic streptococcus of human origin.

6. There is evidence that gives credence to two theories: (a) that the infecting organism was originally a scarlet fever streptococcus particularly in view of the serologic behavior of the cultures, and (b) that passage through

the cow changed the organism making it dissimilar from the typical Dick strains in requiring a lessened oxygen tension to obtain optimum growth.

7. The disease produced by the Petersburg strain differed materially from scarlet fever in its usual clinical manifestations and more nearly resembled typical septic sore throat.

8. Hemolytic streptococci associated with scarlet fever, erysipelas, and septic sore throat may well be variables rather than fixed strains deserving separate classifications.

Residence Allocation

AN editorial in the January *Journal* made reference to recent progress in residence correction of vital statistics. Since that time, information has come to hand as to dates when certain states began correcting for residence. We are advised that Florida made partial allocations by residence in 1917; New York State made some experimental studies in 1918, and instituted a routine system of correction in 1926; in Connecticut, all tables have been corrected for residence since 1927; and in Rhode Island, since 1930. Doubtless other states than these have begun

publishing residence corrected tables.

The purpose of this statement is not to attempt to establish priority. To do this would demand a very time-consuming examination of many reports, and meticulous weighing of the varying extents to which residence allocation has been carried in different states. Our purpose, here, is primarily to indicate some sources, called to our attention, of residence-corrected statistics covering a period of years; and to encourage the progress of this important method of increasing the significance and usefulness of vital statistics. A. W. H.

Wax-Paraffin Ampules for Silver Nitrate Solution Used in Prevention of Ophthalmia Neonatorum

W. E. BUNNEY, PH.D.

*Associate Director, Bureau of Laboratories, Michigan Department of Health,
Lansing, Mich.*

THE purpose of the study reported in this paper was to develop a satisfactory ampule for silver nitrate solution used in prevention of ophthalmia neonatorum. The ideal ampule would have the following characteristics:

1. It would be made of a material not dangerous if accidentally dropped into the eye.
2. It would be easy to handle so that the amount of silver nitrate solution administered could be controlled and given at the exact instant desired.
3. The ampule would be of such material that it would not crack nor crumble during use.
4. The ampule would have no deleterious action on the silver nitrate so that silver nitrate solution contained in it would remain fresh indefinitely.
5. The ampule would be inexpensive.

Of the materials available for ampule manufacture, glass is undesirable because of the possibility of getting fragments into the eye and because of the difficulty of controlling ejection of the silver nitrate from the ampules. The preparation and use of wax ampules composed of beeswax, paraffin and paraffin oil has been previously described in a publication by Young.¹ These ampules are satisfactory in all respects except that the silver nitrate deteriorates rather rapidly to give an acid solution with a pH of about 2.2 and a deposition of a black precipitate on the

walls of the ampule. Study showed that the beeswax was responsible for this deterioration. In Pyrex flasks silver nitrate solution in contact with beeswax quickly became acid and showed the typical black deposit, while in similar flasks containing paraffin or paraffin oil there was no deterioration over 6 months' observation at room temperature. However, the beeswax was found essential to the formula since paraffin alone or any combination of paraffin and paraffin oil gave an ampule which cracked or crumbled when squeezed. Attempts to neutralize the beeswax by boiling with sodium hydroxide solution gave a more stable ampule but the silver nitrate still deteriorated within 1 month's incubation. Attempts to use a bleached beeswax gave a more attractive ampule but the deterioration was even more rapid than in the unbleached beeswax. Probably the yellow color prevents some deterioration due to photochemical action. An attempt was made to use synthetic waxes in place of beeswax without success, the ampules cracking too easily. Paper thimbles were impregnated with paraffin but it was found that too thick a coating had to be applied to prevent deterioration of the silver nitrate by the paper and that this thick coating made the resulting ampule too difficult to squeeze in ejecting the silver nitrate. It was found that

cellophane could not be used for ampules because the silver nitrate deteriorated rapidly.

It was thought that a satisfactory ampule might be one lined with paraffin and coated with a beeswax mixture so as to assure stability of the silver nitrate and the desirable properties of an ampule made out of a beeswax mixture. Attempts to use a low melting point paraffin for lining failed, since on dipping for the beeswax coat, the paraffin lining melted and boiled through the beeswax coat. Enough beeswax would penetrate to the inside of the ampule to cause deterioration of the silver nitrate. The use of a paraffin melting at 68° to 72° C. eliminated this difficulty. It was found best to add 12 per cent of paraffin oil to the paraffin because this gave a lining which crumbled easily but still had a sufficiently high melting point. If the lining did not crumble easily in squeezing, the hard paraffin lining would break through causing the ampule to crack.

METHOD

The method finally adopted for making the ampule is as follows:

1. Aluminum spindles are wiped with paraffin oil and dipped twice in a mixture of 12 per cent paraffin oil and 88 per cent paraffin melting at 68° to 72° C.

One dip was unsatisfactory because the coating cracked upon cooling. More than two dips were unsatisfactory because the paraffin broke through the beeswax mix coat on squeezing the ampule. The length of the paraffin coat should be a little greater than that of the beeswax (see No. 1, Plate I). This prevents the silver nitrate solution from coming in contact with beeswax.

2. The spindles are dipped in a mixture containing 71 per cent beeswax, 8 per cent paraffin oil, and 21 per cent of a 56° C. melting point paraffin.

The number of dippings varies with the temperature of the mix and of the room. The lower melting point paraffin was used in the mix because it was cheaper. Many other combinations of beeswax, paraffin oil, and paraffin were tried for the outer coat-

ing and found less satisfactory. If more paraffin was used, the ampules were found to crack on squeezing, and if less was used or the paraffin oil omitted, the ampules were found to crumble if squeezed when cold.

3. The ampules are placed in racks for filling.

4. Silver nitrate solution is filled into the ampules.

5. Melted paraffin is floated onto the surface of the silver nitrate solution to seal the ampule.

This insures the silver nitrate solution being in contact only with paraffin. The ampule could not be crimped and sealed in the usual manner because the paraffin lining cracked on squeezing.

6. The rack containing the ampules is inverted over an electric plate and the ampules seared off to a uniform level.

7. The rack full of ampules is inverted over a melted bath of the beeswax mix and the ampules dipped to seal the ends further. The finished ampule is shown in Plate I (No. 2).

RESULTS

A study of the behavior of silver nitrate solution in the old ampule showed that the silver nitrate solution deteriorated rapidly at a temperature of 37.5° C., less rapidly at room temperature, and was quite stable at a temperature of 5° to 10° C. In order to speed up the comparison of the stability of silver nitrate solution in the new ampule with the stability in the old, both kinds of ampules were filled with the same

silver nitrate solution, placed in the incubator at 37.5° C. and tested at intervals as shown in Table I. As a check on the results both kinds of ampules were left at room temperature and also placed at 5° to 10° C. and tested at intervals (Table I).

The variation in the silver nitrate content of the unlined beeswax ampule during incubation at 37.5° C. is interesting. A possible explanation for the initial drop would be the destruction of the silver nitrate and deposition of the insoluble precipitate. The contents of the ampules were filtered before the silver nitrate content was determined. A possible explanation for the subse-

quent rise in silver nitrate concentration is that water passed through the walls of the ampule, and that the silver nitrate ions did not, so that on long incubation a gradual concentration took place. If this is the explanation, it is interesting that the paraffin lining slowed up the process. Evidently at room temperature this phenomenon does not take place to as great an extent since the unlined ampules show only a slight drop in silver nitrate content.

Ampules from three commercial firms and one state laboratory were obtained and examined. The results (Table II) indicated superiority of the ampule described in this paper. It is interesting

TABLE II

COMPARISON OF THE STABILITY OF SILVER NITRATE IN PARAFFIN LINED AMPULES WITH THAT IN AMPULES PREPARED BY OTHER MANUFACTURERS

	Original pH	pH After 1 Mo. Incubation at 37.5° C.
Paraffin lined ampules.....	5.4	5.4
Manufacturer 1	3.4	2.2
“ 2	3.6	
“ 3	2.6	
“ 4	3.6	2.6

that the silver nitrate solutions from these four manufacturers were more acid when received than was that in the paraffin lined beeswax ampule after 6 months' incubation at 37.5° C.

The behavior of the silver nitrate in this paraffin lined ampule will be studied over a period of years, but it seems safe to say at this time that the silver nitrate solution will retain the characteristics of a fresh solution in the new ampules for from 10 to 12 times as long at the relatively high temperature of 37.5° C. as does the silver nitrate solution in the old type of ampule. Because of these results our silver nitrate ampule will be distributed with an expiration date of 1 year, instead of the

present 6 months dating, until further study has been made.

EQUIPMENT

The equipment for making the ampules is shown in Plate II. Constant temperature bath B is used for the paraffin-paraffin oil mixture, and bath C for the beeswax mixture. These baths are regulated to a temperature which keeps the contents fluid without overheating. If the baths are permitted to get too hot an undesirable smoking and a darkening of the beeswax results and, moreover, too many dippings are required to build up a satisfactory coat on the spindles.

Each bath was fitted with a constant

PLATE II—Equipment for Making Ampules

PLATE III—Filling Apparatus

level device. That for bath B has been raised up and is lettered A in Plate II. It consists of a Monel metal box without a bottom. A valve and rubber hose attachment is inserted in the top of the box so that when the box is in position as in bath C, the melted mixture can be poured around the outside of the box and sucked up into it by vacuum applied to the hose connection. A hole in the side of the box at the right height to give the desired level in the dipping end of the bath completes the apparatus. This apparatus has the advantage

of being simple to make, easy to clean, and easy to fill. There is no part to plug up with solidified wax, since the wax or paraffin need not come in contact with the valve. The spindles in the dipping racks shown at the right of the baths are made of aluminum which makes the racks of 60 spindles light enough to be easily handled without fatigue. The handles on the racks facilitate the dipping.

The filling apparatus is shown in Plate III. The ampules to be filled are placed in the aluminum block shown

below A in the plate. This block has three rows of holes which hold the ampules so they will not fall out when the plate is inverted, and yet are not so small as to make loading and unloading difficult. The silver nitrate solution is kept in a black bottle shown in the plate and is filled through an automatic, intermittent siphon dispensing apparatus lettered A. This was devised by Bukoski.² Four-tenths c.c. of silver nitrate solution is found to give a satisfactory ampule. When a block of ampules is filled with silver nitrate solution, melted paraffin is run in on top of the solution from the separatory funnel B. This paraffin solution is kept hot during the filling operation by lowering the funnel into a cup of heated paraffin solution when it is not being used for sealing the ampules. The paraffin plugged ampules are then seared off to a uniform level by inverting the block and searing the ampules on the hot Plate C. This hot plate slopes to the

right and to the front and has a trough on the right and front edges so the melted paraffin and beeswax from the searing runs down the trough into the box placed at its right end. The heaters in the hot plate are chosen so the plate gets warm enough to melt the paraffin and beeswax but not hot enough to burn, thus no smoke or objectionable odor results from this part of the procedure. The block of seared ampules is then dipped in the bath of melted beeswax mixture lettered D. The ampules are dipped while still in the inverted position and this gives a finish coat to the seared end of the ampules which aids in holding the paraffin plug in position so that when the ampule is squeezed in use, the paraffin plug will not be forced out.

Amebic and Other Intestinal Protozoal Infestations in Representative Groups of New York City

RALPH W. NAUSS, M.D., DR.P.H., F.A.P.H.A.,
AND MAY H. SALINGER

*Parasitological Laboratory, Department of Public Health, Cornell University
Medical College, New York, N. Y.*

THE incidence of human intestinal protozoal infestation is widely recognized to be quite general throughout the United States, although according to reports of various investigators, it varies considerably in different localities.

Sumerlin¹ has tabulated the results given in various publications which have appeared during the past 10 years,^{2-7a, 8, 9} in connection with similar data from his own studies of 1,850 persons. The range in percentage of organisms found in these 9 groups was:

	Per cent
<i>Endameba histolytica</i>	0.2-15.6
<i>Endameba coli</i>	4.0-19.6
<i>Endolimax nana</i>	0.8-16.9
<i>Iodameba williamsi</i>	0- 5.3
<i>Giardia lamblia</i>	2.4- 6.5
<i>Chilomastix mesnili</i>	1.3-11.5
<i>Trichomonas hominis</i>	0.1- 5.9

For *Endameba histolytica* infestation higher percentages than these have been claimed by other investigators. In 1911, Sistrunk¹⁰ reported 17.2 per cent in 145 persons examined at the Mayo Clinic; Sanford¹¹ in 1911-1916, 22.5 per cent in 5,000 persons also at the Mayo Clinic; Kofoid and Swezy¹² in 1920, 53.2 per cent among 154 soldiers in California, a majority of whom however had been overseas; Faust,^{7b} in 1928, in Wise county, southwestern Virginia, 20 per cent in

460 individuals examined; and Meleney^{13a} 1929-1931, in rural Tennessee, 17.3 per cent and 38 per cent respectively. However, the percentages given in surveys published during the past 10 years, as tabulated above, seem to represent the variations generally to be expected in the United States. Faust,^{7a} in his 3 specimen survey of 1,000 persons at New Orleans in 1931, found an average infestation with *E. histolytica* of 13.8 per cent, distributed as follows:

	Per Cent
Welfare Clinics and Pediatric Service	7.7
Boys' Home	12.5
Male Medical Wards	27.2
Female Medical Wards	13.1
Obstetric Service	25.2
Medical Students (F. M. Johns)	8.27
Ambulatory Cases (F. M. Johns)	7.26
Private Pay Patients (F. M. Johns)	9.05

These figures show variation in percentage in the various groups studied. Comparing these results with those of somewhat similar group studies made by him^{7a} in Panama during the summer of 1931, Faust was able to show the influence of economic status, personal hygiene and sanitation on the incidence of protozoal infestation. Both groups, which comprised approximately 1,000 and 2,000 persons respectively, present a fairly representative cross-section of

the respective populations. He further indicates that, except for the extremes, the Panama group shows percentages quite similar to the New Orleans group. The extremes referred to, consisted of inhabitants of unsanitated river villages on the one hand, and on the other of American whites living in the tropics under the best practical hygienic and sanitary conditions obtainable, which, as Faust states, "might well be emulated in cool as well as in warm climates."

AMEBIASIS IN NEW YORK CITY

Bishop and Bishop¹⁴ concluded that amebiasis occurring endemically in New York City is probably far more prevalent than is commonly supposed. They were unable to reach any conclusions as to the epidemiology of this condition and believed that more attention should be paid to the detection of carriers.

During the past 4 years the author and his assistants have examined the colonic contents from approximately 850 persons for the presence of intestinal protozoa. About two-thirds of the specimens came to us through the coöperation of the Department of Gastro-Enterology of the former pay-clinic of Cornell Medical School, New York City, and of the Outpatients Department of the New York Hospital-

Cornell Medical Association at the new Medical Center on York Avenue at the East River between 68th and 71st Streets, Manhattan. The balance, comprising about one-third of the total, consisted of New York Hospital patients, of private cases of staff members of this institution, and of an additional 200 adults of various ages, the sexes being about equally represented. The groups as a whole present a fairly representative cross-section of the population of New York City.

The data in Table I comprise the accumulated results of routine examinations of the fecal material which came to the laboratory throughout the 4 years covered by these studies. During the first 2 years, direct examination was largely relied upon, the material being kept warm in thermos bottles until examined and rarely held over for examination for more than 2 hours. During the second 2 year period cultural methods on an ever increasing scale were employed as well. In most instances the material was secured directly from the lower bowel through a proctoscope or sigmoidoscope.*

The results obtained from the first

* Dr. Douglas Palmer, now Chief of Gastro-Enterology Clinic, was most obliging at all times in this connection, and formal acknowledgment is hereby made of this assistance.

270 persons who were examined by direct methods only (observation being restricted to a fresh saline-iodine preparation and a permanent Heidenhain iron-alum hematoxylin stained smear), parallel quite closely percentages reported in 1930 by Andrews and Paulson⁶ from a study of 522 out-patients at the Johns Hopkins Clinic in Baltimore, Md. Their total incidence of protozoa infesting the human intestinal tract was 10.9 per cent, while our total percentage in this series was 9.1 per cent. With the exception of *E. histolytica*, our percentages for individual organisms are somewhat less than theirs. Judging from clinical findings and symptomatology, we are convinced that our single instance of a materially higher percentage for *E. histolytica* is probably at least less than half the true figure for this organism. The consistently lower percentages in the case of other protozoa is also believed to be somewhat less than the true figure. In explanation, we would suggest that this disparity may be due to the small quantity and mucoid character of the

sigmoidoscopic specimens, as well as to the inferiority of the permanent preparations made in the early stages of this investigation. In fact, in such routine surveys as these, it is doubtful if the results obtained from examination of sigmoidoscopic specimens have any superiority over those obtained from examination of material secured in other ways, except where there are observable lesions in the lower bowel. On the contrary, we deem this method in general inferior to direct examination of a loose stool following mild catharsis, or even to examination of a normal stool which has not been subjected to desiccation in the rectum. If, in addition, one applies the generally accepted dictum that a single specimen examination reveals not more than one-third to one-half of the protozoa actually present in the bowel, it can readily be seen that the percentages now reported for this first group of 270 persons are undoubtedly low and should not be accepted as adequately representing the true percentages of intestinal protozoal infestation of this group.

As for the cultural results shown in Table I, in which 75 of the 184 cases so studied were checked by direct slide examinations, it should be pointed out that these were cases more or less selected on the basis of the sigmoidoscopic findings, history, and symptomatology. The results obtained seem to indicate the value of culture alone in the study of properly selected sigmoidoscopic material. Further discussion of the actual advantage to be derived from selective culture will be given in connection with Tables II, III, and IV.

Table II records the results of careful examinations of one fresh stool specimen from each of a group of 222 persons engaged in preparing, handling, and serving food. These persons were employed in an institution where hygienic and sanitary conditions were of the best and where every effort is made to maintain a high degree of excellence at all times. All of the members of this group were adults, the majority were under 30 years of age, and the sexes were about equally represented. Rarely was any history given pointing to gastrointestinal symptoms which might lead one to suspect the possibility of any kind of parasitic intestinal infestation. In case of the most pronounced and persistent amebic cyst carrier, where repeated inquiry was made in regard to bowel symptoms, the replies were consistently of a negative character.

On all suitable specimens, a saline-iodine preparation, a cyst concentrate and a Heidenhain hemotoxylin stained smear, were made and studied. Cultures were not, however, made routinely, this method of search being reserved for confirmation of the other findings, *i.e.*, when the findings were open to doubt, or suspicion had been aroused in the course of observation of the saline-iodine or other preparations. In order to insure freshness and correct identification of individual specimens, these

were obtained under proper supervision, placed in pint cardboard containers with tightly fitting lids, promptly delivered, and placed in an incubator until examined.

With the exception of attempted cyst concentration, which was usually postponed until the end of the day, every effort was made to carry out the various procedures promptly on a fresh warm stool. By so doing, we were frequently able to observe motility and to judge relatively the number of vegetative and cyst forms, and their possible significance at the time the stools were passed.

The percentages of infestation presented in Table II, we believe, represent fairly accurately, though not completely, the relative numbers of vegetative and cyst forms for the various protozoa observed. A parallel study of the same specimen by the different methods of search employed by us also serves to evaluate to some extent the relative effectiveness of the various modes of examination utilized. For example, an attempted concentration of cysts by the method devised by Yorke and Adams¹⁵ proved to be disappointing. This method, given by Thompson and Robertson,¹⁶ is as follows:

1. Make as fine an emulsion as possible of a portion of feces about the size of a walnut. The feces should be placed in a mortar and rubbed up with tap water.

2. Mix this fecal emulsion with about 500 c.c. of tap water and place the mixture in a tall glass cylinder in which it is allowed to stand for 15 minutes.

3. At the end of that time three layers have more or less separated off. On the top there forms a sort of scum, at the bottom a considerable amount of sediment, while the bulk consists of a fairly even suspension of fecal particles which also contains the bulk of the cysts. Remove the scum from the surface.

4. Syphon off the remainder of the fluid, leaving the debris at the bottom of the cylinder and about an inch of fluid above it untouched. Discard the scum and the material at the bottom of the cylinder and place the intermediate fluid in a clean cylinder.

5. Allow the fluid to stand overnight. The cysts now precipitate to the bottom of the cylinder.

6. Syphon off the supernatant fluid, and this time discard it, retaining the deposit at the bottom of the cylinder.

7. This precipitate should be washed several times by shaking up with water and centrifuging each time.

(According to our experience, satisfactory results can be obtained by direct examination of this sediment, thus obviating additional centrifugations.)

In so far as this method of attempted concentration of cysts as a means of direct search is concerned, it would appear from our experience that it has little advantage over the study of saline-iodine and permanently stained preparations, except in the case of *Endameba coli* cysts. Apparently no very appreciable or consistent actual degree of the cyst concentration may be expected in case of the smaller protozoal cysts, with the possible exception of *Giardia*. Our conviction in regard to this matter is that the more or less colloidal condition of the material found in the average stool specimen makes consistent concentration, at least for the smaller cysts, quite unreliable, and our experience certainly does not justify its use as an exclusive method of search. It does, however, appear to be useful in conjunction with other methods, particularly in the preparation of fecal material for culture. We have tried certain other methods recommended for concentration of cysts, but not with very gratifying success.

Little need be said here about the value and necessity of the properly prepared and stained smear. This should always be made and used as an ultimate check-up and for future reference. We found it of inestimable value in these studies, particularly when employed to confirm the results obtained from cultures. We did not find it practicable to stain from culture as we should have done if it had not entailed too much

additional routine at the time. Checking up the results of culture against those of corresponding stained preparations, we are able to show that the relatively high percentage of apparently positive cultures for *E. histolytica* may be accounted for. A careful study of the stained smears made at the same time as the positive amebic cultures reported in Table II and following tables, revealed that in about half of them no evidence of *E. histolytica* could be found, whereas *E. coli* cysts were invariably found.

The Difco Bacto Liver Infusion Agar with horse serum diluted in saline (1:10), and whole rice flour as devised by Cleveland^{17a} was employed as medium. Cleveland states, "So far as the amebae of man are concerned, this medium appears to be practically specific for *E. histolytica*." Contrary to his experience we have been able to grow *Dientameba fragilis* fairly consistently on this medium employing the horse serum saline in dilution of 1-10, but agree with him in his statement that "Evidently *D. fragilis* is more common than the surveys that have heretofore been made indicate."

Since the publication of Cleveland's article, Arnett, Weinrich, and Stabler¹⁸ found by direct stain an incidence of 3.5 per cent of *D. fragilis* in "A survey of 401 college students for intestinal protozoa." They state that "An incidence of 3.5 per cent in this survey indicates that *D. fragilis* is not so rare as commonly supposed."

Tables III and IV comprise the findings in 55 persons selected from the 222 reported in Table II, and are designated as groups 3a and 3b. These were either positive for one or more protozoa upon the first examination, or our impression was of such a character as to prompt us to call for a second specimen at once. In compiling Table IV, our conclusions were based on the final result of the examinations of the

two specimens submitted by the same person at different times. Our purpose in presenting these tables is to show: (1) the effect of a second examination of a stool specimen by the various methods employed by us and (2) to analyze further the probable identity of amebae obtained in culture. In this connection, it must be kept in mind that the percentages given in Tables III and IV only apply to this group of 55 selected cases (groups 3a and 3b). A number of these were found to be positive upon examination of the first specimen as recorded in the complete one specimen survey given in Table II. Therefore these percentages should be employed only in connection with this Table II for analytical and comparative purposes.

As to the value of making subsequent examinations of specimens from the same person, particularly when the first examination gave positive results for one or more protozoa of whatever sort, or in case suspicion was aroused in consequence of the first examination, it

may readily be seen that such procedure is certainly justifiable. A similar third examination of about 20 persons included in Tables III and IV, would seem to indicate that triple examinations have some further advantages, but that the proportionate percentage increases would be somewhat less. This agrees in general with what others have reported on this point.

Regarding the identity of the amebae briefly referred to in the discussion of Table II, our findings, as recorded in Tables III and IV, seem to warrant the conclusion that in addition to the excystation and growth of *E. histolytica* and *E. coli* and multiplication of *D. fragilis* in culture on Cleveland's medium, *Endolimax nana* may appear in vegetative form in a not inconsiderable number of instances. With *Iodameba* we did not get any apparent positive results in culture, but the number involved (2 positives by other methods) does not justify any definite conclusion. The flagellates *Trichomonas hominis*, *Chilomastix mesnili*,

and *Embadomonas intestinalis*, seemed to grow quite readily, judging from the small number of cases which came under our observation. All of these were positive in culture as well as by one or more of the other methods of search employed.

The total percentage of *E. histolytica* found in Group 2 (Table II), comprising 222 food handlers, was 5.4 per cent based on a single specimen survey. Group 3a (Table III), composed of 55 persons selected from Group 2 (Table II), for further examinations represented nearly 85 per cent of the positives in Group 2 (Table II). A comparison of the total percentage of 18.4 per cent positives for *E. histolytica* in Group 3a (Table III), with the 27.3 per cent of like positives in Group 3b (Table IV), shows an approximate increase of nearly 50 per cent in positive results for *E. histolytica* in these 55 persons, whose stools were examined a second time. If in lieu of a second specimen examination of the 167 persons remaining in Group 2 (Table II)

(in which two additional cyst carriers of *E. histolytica* were revealed upon inspection of the Heidenhain iron-alum hematoxylin stained specimens), one were to apply a similar approximate ratio of increase, namely 50 per cent, a percentage of positives of between 7 and 8 per cent might be anticipated. Assuming in addition that a third specimen examination of the whole of Group 2 had also been made, it seems reasonable to predict that the total number of positive amebic cyst carriers in this group of food handlers might possibly have been somewhere between 9 and 10 per cent.

DISCUSSION

At the present time there appear to be two outstanding facts deducible from data available on the prevalence of amebiasis and amebic dysentery in non-tropical countries, namely that comparatively few cases of the latter are recognized or even suspected, and that laboratory evidence reveals the presence of cysts of *E. histolytica* in sig-

nificant percentages in all groups of the general population. The question, therefore, arises as to whether the mere presence of any considerable group of individuals harboring cysts of this parasite constitutes a real public health hazard or only a minor personal health menace. Under similar circumstances and conditions, as Faust^{7a} has shown, there appears to be little difference in so far as climate is concerned. Sporadic cases of active infection with *E. histolytica* not infrequently occur in non-tropical localities, where the evidence points to a purely local origin. While we have not at the present time many reported cases of such individual instances, where the epidemiological evidence is complete, nevertheless, most workers familiar with this subject have little doubt that inception of infestation or infection is undoubtedly occurring more or less frequently. These cases may manifest no symptoms or no more than the mild, indefinite, frequently unrelatable, gastrointestinal symptoms commonly complained of by people in general.

As evidence on this point, Craig¹⁹, p. 8 claims to have seen 7 cases of liver abscess occurring in individuals who had never been out of the United States and who had never suffered from dysentery or repeated attacks of diarrhea, and Mackie and Nauss²⁰ reported recently on an investigation of familial infestation and infection where circumstances were such that the original infestation must have been contracted in or near New York City. Sanford¹¹ also pointed out that the majority of their positive amebic cases were undoubtedly endemic to the Northwest United States.

Such a view seems to conform with our present knowledge regarding this condition. Active recognizable symptoms are the exception, although varying numbers of individuals are infested with *E. histolytica* as revealed by the

finding of the characteristic cysts in the bowel contents. Consequently, we are inclined to look upon the symptom-manifest case of amebiasis as somewhat incidental. This appears likely to be the case also when the disease takes on epidemic characters although the underlying causes may be entirely different. It seems quite possible that the depressed resisting power of the gut wall may play the major rôle in this connection. Such factors as mechanical, nutritional, and toxic trauma, originating from within as well as from without, might constitute essential contributing etiologial factors. In other words, the infestation in most instances may be quite superficial with few, small, scarcely recognizable lesions which heal quite rapidly and may reappear elsewhere. This was found to be the case at autopsy by Bartlett²¹ in Egypt during the World War, and by Hegner and colleagues²² in 1931, in the majority of monkeys infected by the administration of washed cysts *per os*.

In regard to the rôle which intestinal bacteria may possibly play in this connection, Cleveland and Sanders^{17b} found that the pathogenicity of their pure line strain of *E. histolytica*, diminished greatly after being in culture for 1 year, but that liver or intestinal passage seemed to increase its virulence. In order to determine whether the ameba or the bacteria regained pathogenic qualities, bacteria from amebic cultures which had been through several liver passages were inoculated together with cultures of *E. histolytica* which had apparently lost their virulence. An increased incidence of liver abscess followed. It was then concluded that the amebae were unable to maintain themselves in the liver unless accompanied by bacteria capable of doing some damage to this organ. Cleveland and Sanders also believed that the increase in incidence of intestinal infection which they obtained after

repeated liver passages of the amebic cultures may have been due to the increased virulence of the bacteria rather than to that of the ameba. The outcome of an experiment by the writer during the course of amebic cultural studies several years ago affords still more positive evidence of the probable selective accessory action of bacteria.

Cultural strains of *E. histolytica* which had been isolated from 2 clinical cases of amebic dysentery respectively about 6 and 1½ months previously, were employed in this experiment. Kittens of the same litter, of approximately the same weight and physical condition, were inoculated with these cultures per rectum through a small catheter after a cleansing enema. Only the kitten receiving the younger culture showed signs of infection, as indicated by diarrhetic stools, rapid loss of weight, failing appetite, and death within about 2 weeks. The other showed no signs of reaction, although repeated attempts were made to infect with the older strain, until it had been injected previously or simultaneously with a broth culture of *B. coli* of the hemolytic variety. This strain, received from Dr. John C. Torrey, had been recently isolated from a case of nonspecific ulcerative colitis and has proved unusually virulent for mice and rabbits. Within a few days of this dual inoculation with the apparently innocuous amebic culture reinforced by the presence of a virulent strain of *B. coli*, the kitten began to pass soft stools with considerable amounts of mucus, containing characteristic vegetative forms of *E. histolytica* which were repeatedly found microscopically. This kitten recovered completely after several weeks.

The significance of this and subsequent experiments, in line with Cleveland's work and belief already referred to, will be discussed later in a paper devoted to the pathology of amebiasis and the significance of cyst carriers.

Suffice it here to state the author's suspicion that intestinal bacteria may possibly play a very important accessory rôle in aiding *E. histolytica* to penetrate the intestinal mucosa and in contributing materially to the ultimate formation and probably advancement of the characteristic end product, the amebic ulceration so familiar to the pathologist.

Finally, with reference to the possibility that amebiasis may manifest true epidemic characters, a study of the reports thus far published relative to the outbreak originating in Chicago last year strongly suggests gross contamination of food or water or both as the outstanding epidemiological probabilities. This statement is supported somewhat by experimental evidence in so far as success in acutely infecting laboratory animals depends on the administration of comparatively large doses of ameba. Infection may occur directly from a cyst infested food handler, but it seems rather doubtful if any considerable number of individuals would be acutely infected in this manner at the same time. Hence the appearance epidemically of cases of clinical amebiasis would appear not to be the rule unless a large number of cysts of *E. histolytica* have been ingested by various persons at or about the same time. Epidemic prevalence of amebiasis is probably therefore, associated with gross contamination of food or water or both. Ordinarily it would seem that direct hand to mouth, food or utensil transmission could rarely accomplish this result.

SUMMARY AND CONCLUSIONS

1. A brief review is given of published reports of human protozoal surveys made in the United States and Panama.

2. Surveys for intestinal protozoa in several groups of persons in New York City, thought to be representative of this locality, are presented in tabular form with explanatory matter and relevant discussion.

3. Different methods of search for protozoa in stools are compared as to their value and desirability.

4. The limitations and value of cyst concentration and culture as methods of search are briefly discussed.

5. Amebic infestation and amebic dysentery are discussed briefly in the light of present knowledge and experience.

ACKNOWLEDGMENTS—The author wishes to express appreciation to Prof. D. H. Wenrich and Dr. Robt. M. Stabler of the Department of Zoölogy, University of Pennsylvania, for assistance rendered in identification of species in question relative to interpretation of results of culture of protozoa.

Grateful acknowledgment is also hereby made to Dr. Lucy M. Crawford of the New York Hospital for most effective coöperation in procuring satisfactory fecal material, and to Josephine Wells and Elizabeth Montu, for voluntary technical assistance rendered during conduct of the latter part of this work.

An Outbreak of Epidemic Cerebrospinal Meningitis in a C.C.C. Camp*

MAJOR WESLEY C. COX, M.C., U.S.A.

Laboratory, Walter Reed General Hospital, Washington, D. C.

CIVILIAN Conservation Corps Company No. 1758 arrived at Camp in the Northeastern Section of Indian Trail Park, Dent County, Mo., on October 27, 1933, from Nashwauk, Minn., where the Company had been stationed for approximately 6 months. The Company had a strength of 3 officers and 215 junior C.C.C. enrollees, between ages of 18 and 25 years. The majority of the enrollees were housed in four 1 story, wooden barracks, 20 ft. wide by 100 ft. long, heated by wood burning stoves. Approximately 40 sq. ft. of floor space per man was allowed. The enrollees slept on standard, canvas, camp cots arranged along each side of the barracks. The cooks, truck-drivers, and special duty men were housed separately. The officers and work superintendents occupied individual rooms in officers' quarters. The forestry foremen occupied small log cabins, 2 to 3 men to a cabin.

On October 30, 1933, an enrollee who bunked in Barracks No. 2 (see Chart I), developed clinical signs of epidemic cerebrospinal meningitis and was transferred to the hospital at Rolla, Mo. The diagnosis was confirmed by the laboratory findings. This man died, November 2, 1933. The Company was placed under a working quarantine to extend for 10 days following the development of the last case of this disease. The Camp

Medical Officer examined all men daily and special care was taken not to overwork or fatigue any of the men. No secondary cases developed and the quarantine was lifted after the 10 day period had elapsed.

Upon the release of the Company from quarantine, an enrollee who had bunked next to the man who had developed meningitis and who had constantly chummed with him, received permission to move from Barrack No. 2 to Barrack No. 4 (See Chart I).

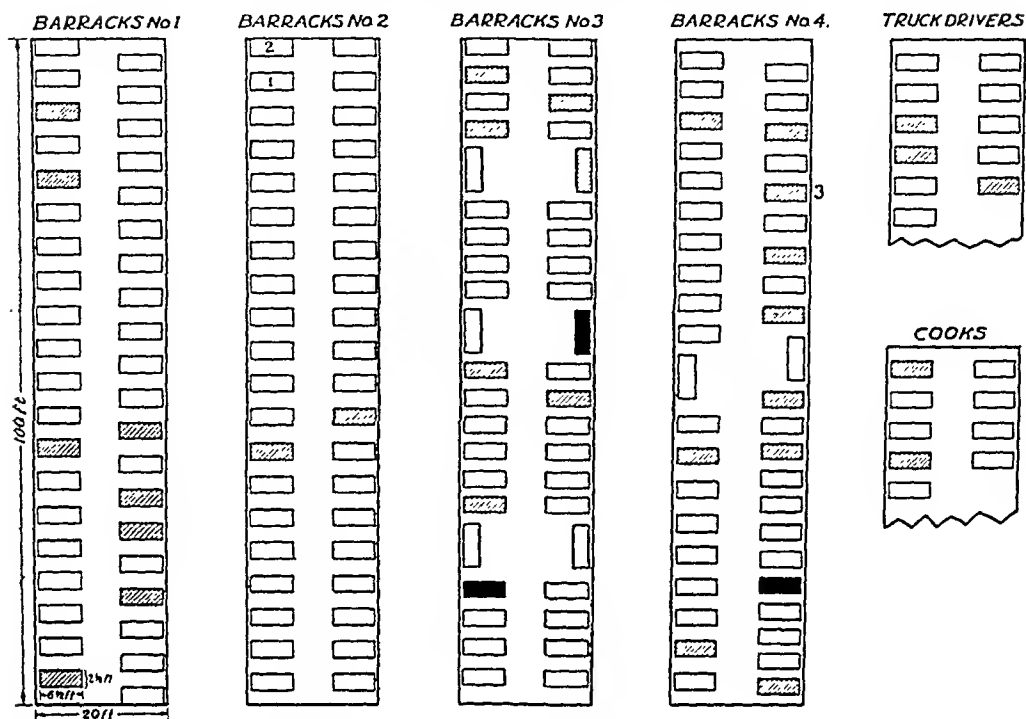

The routine work of trail making, road building and forestry was carried on by the members of the Company during the fall and winter, 1933-1934. During this period the health of the Company was excellent. Leave to visit home was granted all enrollees during the Christmas holidays and passes to visit nearby cities and communities were issued weekly. A number of enrollees were discharged in January and new men enrolled at this time.

Epidemic cerebrospinal meningitis reappeared in this camp on March 25, 1934, with the development of a single case followed by a second on March 26, and a third March 27. Five suspects were hospitalized on March 28, but none of the suspects developed the disease. Two of the patients died.

Upon notification of this outbreak, the Commanding General of the Missouri District and the District Surgeon immediately visited the camp. Instruc-

* From the Laboratory Service, Station Hospital, Fort Leavenworth, Kans.

Note: One selectee, a carrier slept in supply room.

Two selectees, non carriers, slept in Hospital.

tions were issued for the reduction of the overcrowding in the barracks. To accomplish this, tents were set up and the number of men in each barrack reduced from 42 to 30.

The Corps Area Commander ordered the camp quarantined and the entire company placed in working quarantine, the quarantine to extend until 10 days after the appearance of the last case of meningitis. Nasopharyngeal cultures were taken on all members of the Company in order to detect those who were carriers. All carriers found were to be cultured at intervals of 5 days until 3 successive negative cultures were obtained.

There being no laboratory facilities available locally; on March 27, the Laboratory, Station Hospital, Fort

Leavenworth, Kans., was directed to set up a field laboratory at this camp. In accordance with these orders an improvised field laboratory was set up on March 28, and all members of the Company were cultured before breakfast on the morning of March 29. Because of the long journey by automobile over rough roads, no attempt was made to transport liquid media. For this reason the rapid method of isolation of the meningococcus was not used. No transportable water bath was available so that it was not possible to set up agglutination tests at camp. Sub-cultures on blood slants were kept at 37° C. by means of hot water bottles and transported to Fort Leavenworth, where agglutination tests were set up. On each trip to Fort Leavenworth a fresh supply

of media was obtained for use in the field.

The cultures from the posterior nasopharynx were plated on medium prepared from 1 per cent glucose, beef heart, infusion agar, pH 7.8 to which laked rabbit blood was added. The plates were incubated at 37° C. for 24 hours. Typical colonies were transplanted to slants of laked rabbit blood agar. Identical colonies were stained by Gram's method, in order to eliminate all but Gram-negative diplococci. The slants were examined after 18 hours incubation, all chromogens discarded, typical cultures identified as Gram-negative diplococci, and preserved at 37° C. for final agglutination.

The total population of the camp on March 29 was 209 officers, foresters, and enrollees. A total of 33 (15.7 per cent) were found to carry the meningococcus in the posterior nasopharynx. The organism was identified as a Type II (normal) meningococcus.

The number and percentage of carriers by barracks is given in Table I. With the exception of Barrack 2, which housed the case developing in the fall of 1933, there existed a fairly uniform "barrack rate," varying from 16.6 per

TABLE II

cent to 27.2 per cent. Careful investigation revealed no differences in mode of life or association with other members of the company between the men housed in Barrack 2 and the men housed in the other barracks. It is possible that some of the men housed in this barrack developed the carrier state following their exposure to the disease in October, 1933, and that this temporary carrier state cleared up prior to March, 1934. It is impossible to state how long the carrier state had existed in the two carriers found in this barrack.

The carriers were re-cultured every 5th day until 3 successive negative nasopharyngeal cultures were obtained. Table II gives the results of this survey.

Upon detection of the carriers, the members of the Company were divided into 3 working quarantine groups. One group was composed of those non-carrier enrollees who were to be discharged shortly due to the termination of their period of enrollment. A second group was composed of non-carrier enrollees who were to remain in the Civilian Conservation Corps. The carriers formed the third group. These groups were segregated in separate barracks and tents, messes separately, and

worked separately. A separate latrine was provided for the carriers as were separate bathing facilities.

No cases of meningitis developed in this camp after March 27, 1934. The quarantine, except for the carriers, was lifted April 6. Eighteen of the carriers were released from quarantine April 15, and 13 April 20. Two carriers were transferred to the Station Hospital, Fort Leavenworth, Kans., for further quarantine and finally released May 6.

DISCUSSION

The case of epidemic cerebrospinal meningitis which developed 3 days after the arrival of the Company at Indian Trail Park, undoubtedly acquired the infection during the period the Company was encamped at Nashwauk, Minn.

It is possible that a healthy carrier existed among the personnel of the Company and that this carrier was the cause of the first case as well as the subsequent outbreak.

The distribution of carriers throughout the enrollees of the Company was fairly uniform, Barrack 2 in which the first case developed being the exception. It was from this barrack that an enrollee, found on the survey to be a carrier, moved to Barrack 4.

No carriers were found among the officers or foremen. This group while in constant contact with the enrollees, was housed in cabins under optimum conditions as to floor and air space.

One carrier was found in the group of 5 enrollees who were housed under optimum conditions as to the floor and air space. These men, however, visited the Company barracks, spending evenings associating with their fellow enrollees in the barracks. The carrier rate of 20 per cent for this group parallels closely the general carrier rate for the camp.

The Health Officer of the City of Nashwauk reported that there were no cases of epidemic cerebrospinal meningitis in that city or the surrounding country during the year 1933 or the first 5 months of 1934. The Health Officer of Dent County, Mo., reported that there had been no cases in that county for several years. No cases developed in the other Civilian Conservation Corps Camps in this section of Missouri, one of which was 3 miles, one 15 miles, and one 40 miles, distant from this camp. Members of all the camps in this section visited and congregated in Salem, the county seat of Dent County.

The epidemiological problem is further involved, because of the fact, that, during the Christmas holidays members of the Company visited communities in which cerebrospinal meningitis is endemic, thereby introducing the possibility of a new carrier returning to the camp. It is also possible that one of the men enrolled in this Company in January, 1934, was a carrier.

The origin of the first case of cerebrospinal meningitis and the second outbreak cannot definitely be traced. The development of the carrier state in various enrollees, following the initial case in the fall of 1933 associated with the existence of serious overcrowding in the barracks, offers the most logical epidemiological solution of the second outbreak.

The second outbreak was self limiting, no cases developing after March 27, which was 24 hours before any measures were instituted to correct the overcrowded condition of the barracks and 3 days before the carriers were separately quarantined. The eradication of the overcrowding and the isolation of the carriers until this condition cleared up undoubtedly prevented the development of secondary cases.

Constancy of Characters Differentiating Intermediates in the *Escherichia-Aerobacter* Group and their Interpretation*

EDMUND K. KLINE, DR.P.H., F.A.P.H.A.

Cattaraugus County Department of Health, Olean, N. Y.

THE choice of bacteriological methods by which organisms are to be classified within the *Escherichia-aerobacter* group offers numerous pitfalls, and whatever methods are chosen the differentiation into sections of the group will not always be sharply defined either in the laboratory or in the field.

The basic tests in most general use are methyl red and Voges-Proskauer tests, utilization of citrate as the sole source of carbon, detection of indol, and ability to grow at 46° C. (Eijkman Test). Three genera are commonly recognized as comprising the group: *Escherichia* (MR +, VP —, Cit. —, Ind. ±, Eijk. +); *Citrobacter* (MR +, VP —, Cit. +, Ind. ±, Eijk. ±); and *Aerobacter* (MR —, VP +, Cit. +, Ind. ±, Eijk. —).

While classification by means of these reactions may be challenged in the case of individual atypical cultures, and while it occasionally offers a result that is not supported by confirmatory tests, yet it seems to give a basic working differentiation of generic variations underlying the group. However, when these criteria for section differentiation

are applied there always occurs a certain percentage of organisms that apparently are bona fide members of the group, but yet are intermediate so far as differential characters are concerned.^{1, 2}

The constant occurrence of these intermediate forms can be explained in various ways. It may be that—

1. The group is so heterogeneous as not to permit strict classification into sections.

2. The strains in the group readily fluctuate in certain characters so that they vary in different environments.

3. As the bacteria in the group grow in natural conditions they are constantly dissociating into strains showing new reactions.

4. The various cultures showing intermediate reactions may not be pure strains but mixtures of two or more different strains.

It is the purpose of this paper to present certain experimental evidence bearing on these considerations tending to show that the above mentioned characters do not readily fluctuate with either changes in environment or colony morphology (dissociation), and that many of the intermediates are not mixed cultures.

The 6 experiments below, selected from a wide variety of similar experiences, illustrate the results obtained in respect to variation of differential characters.

* Read before the Laboratory Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 6, 1934.

1. *Growth in Milk*—Eight various strains of the *Escherichia-aerobaeter* group were cultured in milk with daily transfers for 53 consecutive days. Every week they were tested by the various differential tests. Three cultures were MR +, VP —, Cit. —, Ind. +; 1 was the same with the exception of being Ind. —; and 4 were MR —, VP +, Cit. +, Ind. —. No variations in these characters occurred throughout the experiment although 1 culture lost its power to produce gas from lactose between the time of the 14th and 21st transfer and failed to regain this power to the end of the experiment.

2. *Growth in the Presence of Inhibitory Dyes*—In growing these organisms in lactose-peptone brilliant green broth, delayed lag phases frequently occurred.³ In one such experiment a typical *Aerobacter-aerogenes* (MR —, VP +, Cit. +, Ind. —, Eijk. —) was inoculated in a test series and delayed growth appeared in 2 tubes at 72 hours, in 2 tubes at 96 hours, and in 1 tube at 120 hours. All of these cultures were tested by the differential tests and showed no change.

3. *Growth in Cold Blooded Animals*—While studying effects of salamanders on spring water supplies,⁴ several experiments were carried out to ascertain if habitation in the gastro-intestinal tract of the salamander would change the type of *Escherichia-aerobaeter* organisms. When salamanders are placed in sterile water and starved they become free from such organisms. Salamanders were placed in large mouthed, one liter, Ehrlenmeyer flasks containing about 100 c.c. of sterile water, and every 24 hours were transferred to similar flasks. After each transfer the water was examined for the presence of the group and the organisms isolated were typed.

In one such experiment a large purple salamander (*Gyrinophilus porphyriticus*) was starved and then fed 1/10 c.c. of a 24 hour broth culture of *Escherichia coli* (MR +, VP —, Cit. —, Ind. —, Eijk. +). Organisms were obtained from the animal for 14 days thereafter and typed. The results were constant with the exception of the indol tests. Indol positive cultures were encountered in 20 of the 36 tubes showing fermentation.

An exactly similar experiment used a frog. This frog after being fed a culture of the same strain of *Escherichia coli* showed organisms for 30 days. These were typed and their reactions were again constant with the exception of indol. Indol producers were encountered in 64 of the 111 cultures.

4. *Growth on Stones Immersed in Water*—As control of the above animal experiments,

small stones were soaked in similar cultures and transferred from flask to flask of sterile water in the same manner as the animals. These experiments gave peculiar results in that in some cases the organisms died out very soon, as early as the 8th day, and in others they persisted for very long periods; in 1 case 544 days, when the experiment was discontinued.

In those experiments where the organisms died out rather promptly there was no change in type. In the experiment continued the longest the organism placed in the flask was constant in type for the first 185 days after which several atypical forms appeared.

5. *Growth in Soil*—Lengths of 3 in. stove pipe were filled with soil and carefully sterilized by repeated autoclaving. These were then joined with sterile precautions to form a pipe 20 ft. in length. All joints were taped and shellacked. Copper teats had been previously soldered to the pipe at intervals and rubber tubes and clamps were placed on these to serve as sampling points. Sterile water was introduced at the head of the pipe and permitted to seep slowly through the soil. Samples of this water drawn from all taps over a test period proved to be sterile. An emulsion (approximately a billion organisms in a liter of water) of a carefully purified culture of *Escherichia coli*, recently isolated from human feces was then run into the soil column. Thereafter, sterile water was run through the column at the rate of about 1 gal. each 24 hrs. The organism was recovered from the first tap (about 8 in. of soil) in 3 hrs., after 6 hrs. it was recovered 7 ft. from the inlet, and after 36 hrs. it was uniformly recovered from the entire length of the pipe. Thereafter it was recovered intermittently from all levels of the pipe for a period of 410 days, when the experiment was discontinued. On the 410th day organisms were isolated from the 1st and 4th taps which were exactly the same in all the above characters as the original culture. In all 726 cultures were isolated and typed from this pipe (Chart I).

6. *Effect of Dissociation*—An unstable culture of *Escherichia coli mutabile* (MR +, VP —, Cit. —, Ind. +, Eijk. +) giving rough and smooth colonies was transferred daily, roughs being picked from roughs and smooths from smooths. After 21 days the cultures gave the same reactions showing that no change in these differential characters accompanied a change in colony morphology.

PURIFICATION STUDIES

Three methods are available for the purification of cultures: (a) Repeated

picking single cells from minute droplets of emulsions or from thin agar smears of dilute emulsions. The types of organisms recovered after these painstaking purifications are shown in Table I.

There are many references in literature to show that all types of cultures can be obtained from any natural source if proper enrichment methods

METHOD OF PURIFICATION BY USE OF SELECTIVE ENRICHMENT MEDIA

are used.² Our experience confirms these general findings and shows that no special type is solely present in any given environment. The various series of cultures isolated from different habitats during our several years experience are divided among the three main divisions of the group, as shown in Table II.

DISCUSSION

The *Escherichia-aerobacter* group of bacteria consists of a few simple generic types and many intermediate forms. These intermediate forms are frequently mixed cultures but even the most painstaking methods of purification fail to reduce the group to a few standard types. All of these are comparatively stable in pure culture and do not fluctuate in regard to basic differential characters in short periods even though their environment is altered, nor do they dissociate to new types although they may show marked changes in colony morphology.

No natural environment is exclusively the abode of any single type of organism and no single type of organism is found exclusively in any natural environment. Some environmental conditions favor the development, and consequent overgrowth, of special types, and some types grow very poorly or not at all under certain environmental conditions. Therefore, mixed cultures will fluctuate with environmental changes through the overgrowth of one or the other component of the mixture.

Tests such as the utilization of citrate and the Eijkman test which have been suggested as differentiating fecal and non-fecal strains of the group do not indicate the *immediate* source of the organisms, since laboratory experiments show that any variations in these reactions were matters of long periods in altered environments.

For practical purposes a very general grouping of the various strains into

generic groups will yield all the information that can be utilized in practical field work and exact classification into smaller groups may be left to the research laboratory.

APPLICATION TO PROBLEMS OF WATER ANALYSIS

Since the *immediate* source of the various strains is not indicated by their cultural characters, interpretation of the presence of certain members of the group through such tests or groups of tests on either pure or mixed cultures is apt to lead to erroneous conclusions. However, the proportionate numbers of the various generic groups present in an inoculum may, in the future, justify drawing conclusions concerning the immediate environment through a knowledge of what environmental conditions favor the overgrowth of certain groups.

Interpretation of this knowledge will have to be based on experience, and this experience can only come after present enrichment methods are discarded and new methods developed for the recognition of sections of the group without preliminary enrichment. Future efforts to clarify the meaning of the presence of the group, both regarding laboratory methods and interpretive values, should be in this direction.

SUMMARY

Intermediate cultures of the *Escherichia-aerobacter* group isolated from natural habitats are frequently mixed cultures but careful purification studies including single cell isolations have failed materially to reduce the number of kinds of intermediates.

Strains of the group have been tested for constancy of the methyl red and Voges-Proskauer tests, utilization of citrate as the sole carbon source, detection of indol and ability to grow at 46° C. (Eijkman test). Pure cultures were grown in milk and brilliant green broth, fed to cold blooded animals,

inoculated into soil, and grown on stones immersed in water.

All the above characters were constant during weekly tests when 8 strains were grown in milk and transferred daily for 53 consecutive days. When a salamander and a frog were starved and then fed broth cultures of *Escherichia coli*, cultures recovered daily for 14 and 30 day periods respectively yielded constant characters with the exception of indol formation. Twenty of the 36 cultures (55.5 per cent) recovered from the salamander, and 64 of the 111 cultures (57.6 per cent) recovered from the frog were indol positive.

Sterilized soil which was held in a 3 in. stove pipe 20 ft. in length was inoculated with a carefully purified culture of *Escherichia coli*. Sterile water was permitted to seep slowly through the soil for 410 days. Of 726 cultures isolated at various sampling points during this period, 560 cultures (77.1 per cent) retained the same characters as the original culture (MR +, VP —, Citrate —, Indol +, Eijkman +). The remaining 166 cultures (22.9 per cent) varied in respect to the methyl red, citrate or Eijkman tests, but no variation occurred before the 47th day. The fact that 75 cultures (10.3 per cent) isolated after the 95th day were able to utilize citrate as the sole source of carbon suggests that citrate fermenting forms may be strains

of species in the genus *Escherichia* and that there may be no justification for classifying them in a separate genus (*Citrobacter*).

While the results of these studies indicate that different environmental conditions result in changes in the characters of members of the *Escherichia* group, particularly with respect to indol production, the utilization of citrate and the Eijkman test, the complete persistence of the characters which differentiate *Escherichia* from other types of colon organisms in changed environments in a large percentage of the cultures for long periods of time shows that as an index of fecal pollution, reliance should be placed on the identification of this species rather than to expect these variable tests to indicate the *immediate* environment from which the organism is isolated.

Fevers of the Typhoid Group in Members of the Civilian Conservation Corps During 1934

GEORGE F. LULL, M.D., DR.P.H.

Lieutenant Colonel, Medical Corps, U. S. Army, Statistical Subdivision, Surgeon General's Office, Washington, D. C.

THE incidence of fevers of the typhoid group among enrollees of the Civilian Conservation Corps was the subject of a brief report¹ published in this *Journal* some months ago. During 1934 data have been collected relative to this group of fevers among the large body of males of susceptible age who are working, largely in rural communities, scattered about in over 1,000 camps.

There were 79 cases reported during the year, one of which was called paratyphoid "A," but the diagnosis was not substantiated by anything more than agglutination tests. The patient had received a vaccine containing the paratyphoid "A" fraction so he has been considered among the typhoid cases. One other case was a para "B" infection.

The enrolled strength of the C.C.C. on January 1, 1934, was 278,517. The enrollees are taken in for 6 months' periods which terminate at the end of March and September, so that there is 1 group exposed for 6 months and 2 additional groups exposed for 3 months each. During 1934 there were nearly 400,000 different individuals enrolled, and hence exposed to infection.

The contents of the typhoid vaccine were altered during the year. The old type vaccine contained 750 million

typhoid and 250 million paratyphoid "A" organisms. New vaccine was issued during the first quarter of the year so that all enrollees entering after April 1 received a vaccine containing 2,000 million typhoid and no paratyphoid organisms.

An analysis of the 78 cases shows that 41 received the new vaccine and 23 the old; 13 received 2 doses of the old and 1 of the new; and 1 case received 1 dose of the old and 2 of the new.

Many of these cases were treated in rural hospitals where laboratory facilities were not available for bacteriologic work, so that the diagnosis was based on the clinical findings only. This was true in 48 of the cases, while in 30 the causative organism was obtained from blood, feces, or urine, and proven bacteriologically.

The following was found to be the relation of onset of the disease to time of immunization:

Number sick before being vaccinated	6
During the 1st month following vaccination	5
Between 1 and 3 months following	29
Over 3 months	38

Cases were reported from all corps areas except the Sixth, which comprises the States of Illinois, Wisconsin, and Michigan. By states the distribution was as follows:

	Cases
Idaho	23
Tennessee	22
New Hampshire	6
Arizona	4
Maine	3
Massachusetts	3
Texas	3
Mississippi	2
Kentucky	2
Vermont	1
New York	1
Virginia	1
West Virginia	1
Arkansas	1
Minnesota	1
North Dakota	1
Colorado	1
New Mexico	1
Oklahoma	1

There were 2 outbreaks of considerable size, one at LaFollette, Tenn., and the other at Avery, Ida.

The outbreak at LaFollette occurred in a company recruited from New York City and the urban region of northern New Jersey. The first case appeared on June 13, 1 on June 14, 1 on June 16, 2 on June 17, 3 on June 25, the last appearing on June 28—15 days after the first. An investigation showed that typhoid had existed in the community and that cases had occurred in the families of 2 farmers living near springs the water of which had been used by the men contrary to orders. Milk had been purchased directly from a number of farmers by individual enrollees. In 11 of the cases the causative organism was isolated. All recovered.

At the camp near Avery, Ida., the first patient became ill on July 21, and up to August 19 there were 19 cases with 1 death. The source of this outbreak is thought to have been an infected water supply.

The only case of para "B" infection occurred in an enrollee in New Hampshire. This man had not been out of camp for a month prior to his illness and there were no other cases either in the camp or in the civilian community near by. Bacteriological examinations were all negative except serum agglutination which was positive for B in dilutions of 1 to 6,400, while it agglutinated *B. typhosus* in 1 to 20, and paratyphoid "A" in 1 to 80 only. The case terminated in recovery.

There were 6 deaths among the 79 cases, a fatality rate of 7.69 per cent. Three of these deaths were in Idaho, and 1 each in Maine, Kentucky, and Texas. One fatal case was admitted to hospital 5 days after his first dose of vaccine, another 2 weeks after completion of prophylaxis, and the 4 others at various times from 2½ to 7 months after vaccination.

The incidence and death rates based on an average strength of 292,698 were 0.27 and 0.02 per 1,000, respectively. If we consider these rates based on the number of individuals exposed, they would be 0.20 and 0.015.

Child Care in Vienna

E. V. THIEHOFF, M.D., F.A.P.H.A.

Health District No. 7, Gladwin, Mich.

IN spite of the present crisis in Austria, Vienna is setting an example for the rest of the world in caring for her children. Realizing that this crisis proves most destructive to family life, the city of Vienna has taken over the care of her needy children, offering them not only a helping hand but in many cases a happy home.

The man who instituted and who was in charge of this work is the famous anatomist, Dr. Julius Tandler, formerly Chief of the Social Welfare Department of the Municipality of Vienna. He linked his name with the whole of public welfare in Vienna. His fundamental ideas have set high standards for all of Europe.

When the writer was in Vienna, one of the first places visited was the Jugendamt (District Child Welfare Center) on Laudongasse. The Municipal Youth Welfare Department is one of the municipal offices which deal with public welfare and social betterment. This department has divided the city of Vienna into 32 child welfare districts, each with its own office. Each center handles, on an average, 2,000 or more children. An interview with one of the directors in the Laudongasse center revealed that there are several directors in each center, each having under his care approximately 400 children.

Through these centers the care of illegitimate or mistreated children is supervised. All illegitimate children are registered immediately after birth. An attempt is made to determine paternity

and if able, the father must contribute to the child's support. If the parents are not employed, the city pays for the child's care. The center has general supervision of the child. A physician, dentist, and nurse are present two afternoons a week to examine children and safeguard their health. No treatment is given. If such is needed, the children are referred to free clinics. The parents are required to come into the center frequently for conferences. Women public health workers, Health Visitors of the Municipality, as they are called, make visits to the schools and homes to determine how the children are progressing, and if they are being properly treated. The center sees that the child, arriving at school age, is placed in a school, starting with a kindergarten. Parents not caring for their children properly are brought before a judge. People wishing to care for a child may obtain one through the center. Complete records of each child are kept on file in the center office.

Another child caring institution visited was the "Kinderübernahmestelle" or Municipal Reception Institute for Children. It is in effect an orphans' home conducted by the city of Vienna, a home for deserted, mistreated, illegitimate children or the children of parents who cannot care for them. Here the children are kept for 6 months and then returned to their homes. If a child has no home an effort is made to find a suitable home for him. The building itself is modern and well arranged, with a capacity of 200. Only well children

are housed. Sick children are sent to a nearby Children's Hospital. The rooms are divided into sections, one for infants under 1 year of age, one for children 1 to 2 years old, one for children 2 to 6 years old, and a section for older children.

Of late years there has been a building trend in Vienna—not of churches, museums, palaces or monuments, but of living quarters for the masses. This started soon after the socialists came into power. Within the last 10 years the city has erected modern tenements for 60,000 families of the laboring class. Probably the best known of these is the Karl Marx Hof, consisting of two large units built around beautiful courts. It provides homes for 5,000 persons or 1,400 families. Thus, Vienna has not only provided modern homes for poor children, but has gone a step further and included kindergartens in many of them. Here children from 3 to 6 years of age spend the day in attractive rooms under expert care, which is a great aid to families where both parents work during the day.

The Vienna Municipal Kindergartens or Infant Schools are a part of the welfare activity of the city. The Town Council has entrusted their management to the Municipal Youth Welfare Department.

Since the World War the kindergarten system has been greatly developed by the municipal government. After the war the 57 kindergarten schools were converted into so-called "Volkskindergärten," the hours originally from 9 A.M. to 12 noon and from 2 P.M. to 4 P.M. being extended from 7 A.M. to 6 P.M. This necessitated feeding the children at school. At first breakfast was supplied by the Dutch Relief Scheme and lunch by the American Child Relief Scheme, but since 1922 the municipality has supplied the meals.

In 1934 Vienna owned 114 kinder-

gartens. These are divided into over 300 groups, each group averaging 30 children. The children are mostly drawn from the laboring classes. They are accepted from homes where both parents are away at work all day and where there are poor housing or bad social conditions, endangering the physical and mental development of the child. These children are sent to kindergartens by the District Child Welfare Centers previously described. The contact between the center and the kindergarten is made by the Health Visitor who visits not only the school but also the home. The Kindergarten superintendent has the right to fill vacancies. About half of the kindergartens are held in the municipal dwellings, one-fourth in school buildings, one-fourth in their own buildings, and very few in private houses. Most of the kindergartens are open during the entire year. Great care has been exercised in equipping and furnishing them. The furniture is in proportion to the size of the child. Each school has a terrace, a garden and an open-air playground.

Each kindergarten is divided into groups or classes, the newer schools consisting of only two to four groups. It is felt that the smaller kindergartens are better than the larger where danger of infection is greater. All groups consist of boys and girls, irrespective of age. Formerly they were grouped according to age.

A combination of the Montessori and Froebel principles is used, the best of these two theories being united. The school day is so divided that education, work, and play are brought into proper relation to each other. An attempt is made not only to supply a happy home during the day, but also to make the child better able to associate with others in a group. The teachers outline their work each day but it is not a fixed program, as the children are allowed

some choice. Exhibitions are given annually to display the articles the children have made.

Teaching requirements are very strict. By act of Parliament it has been decreed that only women who have completed courses of instruction in a college for kindergarten teachers will be employed. Of these colleges there are two private schools, one municipal school, and one school of the federal government. In addition to this teachers must have had at least 3 months of practical experience in a public kindergarten. Opportunities are offered for teachers to receive advanced education.

Superintendents are chosen from among former teachers, promoted because of exceptional ability. Their duty is the administration of the kindergarten. They have control over the teachers and assistants and are responsible for their work. All of the superintendents have monthly conferences together.

Medical control over each kindergarten is exercised by a physician who examines each child upon entrance to the school and at frequent intervals. He keeps complete health index records for each child. Any child needing treatment is referred to the proper clinic.

Expenditures for the municipal kindergartens have been increasing year by year with the growth of the system. The only revenues are the contributions made by the parents. The fees are very low. During the present economic crisis only about 16 per cent of the parents have been able to pay even these low fees, while about 24 per cent pay from one-fourth to one-half of the fee. Sixty per cent do not pay anything, the city covering this loss.

Each kindergarten has its "Parents' Association," the purpose of which is to support the work of the school.

One of the last places visited in

Vienna was the beautiful "Sandleiten" Kindergarten, the one-hundredth of these model institutions. It is located in the hilly district on the outskirts of the city near the Vienna Forest. This is a new part of the city and not so long ago was a sandy, waste area, from which "Sandleiten" derives its name. Now this district contains one of the new blocks of municipal dwellings, and here is Sandleiten, the finest kindergarten in Vienna.

At the entrance one is greeted with the words of Dr. Tandler:

"Give to the Child Beauty and Joy.
Childhood Impressions live forever."

Certainly one receives impressions of beauty and joy within.

Adults are allowed to accompany the children only to the doors. Visitors are admitted only by card and then must don cloth overshoes. Thus, every precaution is taken to safeguard the health of these little children.

The reception hall resembles a large picture book as Professor Arthur Brusenbauch has painted beautiful frescoes on the walls and ceilings. These depict events which make the life of children happy.

First the child passes down broad, light hallways to the cloakroom. Here each child has his own hook and locker and here he changes from street clothes to shoes and rompers furnished by the kindergarten. Each child knows his things by a picture sign (a rabbit, a bird, a flower, etc.). In addition, one group of children wears blue shoes and rompers while another wears red. Those dressed in blue know they are to go to the room painted blue with a blue gentian flower painted on the floor while those in red go to the adjoining room painted red and with a red poppy design on the floor.

Next the children must go to the toilet and then wash and clean their teeth. Following this they go to their

playroom where they clean and tidy up their doll houses, feed the canaries, and give the gold fish fresh water. This work being accomplished, they have their gymnastics. The morning exercises follow the rules of modern gymnastics for these small children.

After washing, breakfast is served. The children take turns in serving each other. They learn good table manners. Now it is time for play. The little ones are guided into certain games by the teacher. Songs are sung and stories are told. There is work too with different materials such as crayons, scissors, etc. Soon it is dinner time. Before eating the children must again visit the toilets and wash. Meals are supplied by the Vienna Public Kitchen Service. The meals are prepared according to the famous "Nem" system of Professor Klemens Pirquet which allows, by special calculation, all the calories and vitamins necessary to a child's growth. If any child has a birthday it is celebrated with lighted candles and a plate of sweets. After dinner the room is made tidy and the dishes are washed.

It is now time to rest. The children

lie on little woven straw mats, which in summer time are placed out of doors on the terrace.

The rest period is followed by another period of play and work, the latter in workshops where the larger children are taught to handle tools while the smaller ones build in sand boxes.

In summer the children spend most of their time in the garden. Each group has its own playground and sand box. There are garden tables with gay sun-shades where the children may eat. The wading pool affords much healthful exercise.

Altogether the kindergarten promotes the natural development of these little children. It gives to the children what they would have to go without at home—a sense of order, a community spirit, independence, pleasure in work and play, cleanliness, and culture. Thus, is justified the effort of the Vienna Municipal Kindergarten system which has set the pace for others. One must admire the city of Vienna to have found the courage, the will, and the means, in spite of her many difficulties, to make possible these kindergartens as a protection for her youth.

Function of the Laboratory in the Epidemiological Control of Syphilis*

CHARLES W. ARTHUR

Director of Laboratories, Department of Health, Pasadena, Calif.

WHILE this Association has been traveling to and holding its Annual Meeting, probably somewhat more than 7,500 cases of syphilis have been added to the present year's morbidity totals for the United States. The annual incidence of this disease as reported to public health agencies continues at such a relatively constant level that there is little to indicate much progress in its control. The number of unreported cases is unknown. There are no mysterious factors relating to the disease which are at all responsible for this failure to achieve a lowered incidence. It is not a lack of knowledge but a question of coöperative effort, and among the reasons which have been advanced to explain the continued prevalence of the disease are: the failure of health agencies to provide adequate laboratory and clinical facilities for the diagnosis and proper treatment of known cases and the more or less utter neglect in checking up on sources of infection and significant contacts; the frequent failure of physicians to report cases; the failure of some individuals to seek medical advice or apply for treatment while they are in the early and infectious stage of the disease; and the lack of coöordinated effort where

some communities in which a sound control program is attempted are surrounded by areas in which few if any preventive measures are applied.

There is some indication that the lay public is becoming more appreciative of this problem. However, even with smallpox, the educational method alone has never proved sufficient and only those areas have largely been free of variola where health consciousness has made it possible to pass compulsory vaccination legislation. As recently as 1924, an epidemic of 116 cases occurred in this community, paralleling an outbreak of proportional incidence in the metropolitan area—a by-product of free choice in the matter of vaccination. As commendable and necessary as is the educational approach, there is urgent need for a more vigorous application of medical and epidemiological methods, on a national scale, if the incidence of syphilis is to be reduced.

It is recognized that provisions for the control of this disease vary markedly in various sections of the country. However, where there is a balanced program with the physicians in private practice and public and private agencies sharing the responsibility of control, a more efficient use of available facilities results. An advisory medical committee coöperating with the health department can give very valuable support to any public health program. We have had this experience locally

* Read at a Joint Session of the California Association of Dairy and Milk Inspectors and the Laboratory Section of the American Public Health Association at the Sixty-third Annual Meeting in Pasadena, Calif., September 6, 1934.

especially during the recent poliomyelitis epidemic. With the coöperation of a number of physicians, and through the efforts of the department, at times it has been possible to obtain multiple blood specimens over a period of weeks from significant contacts with infectious syphilitics. There are many individuals who, when treated with consideration under such circumstances, are coöperative. Thus a few cases have been discovered in which the acquisition of the spirochetes was not suggested from gross examination, and the prompt treatment of these patients has undoubtedly been one means of preventing a few new infections. In one such instance, very recently, on the third examination positive tests were found both by complement-fixation and by precipitation, at a time when no local lesion had been discovered. The early treatment of this case which conceivably could have progressed to late syphilis without detection will undoubtedly be of paramount value to the individual, besides representing the control of a potential source of new cases.

The system of reporting the disease by number has often been an obstacle even though it is argued that where names and addresses are required there is an even greater tendency to conceal cases. Reports from several areas indicate that from 40 to 60 per cent of known patients are treated in clinics, hospitals, and state institutions. The names and addresses of these individuals are even now on records available to the health authorities and we hear of no objections either from the patients, the institutions, or the physicians in attendance. The effects of syphilis on the human race are certainly no less serious than are those of poliomyelitis, yet no health department would fail to make an immediate investigation of every case of the latter disease and record all pertinent epidemiological data. If, therefore, the

names and addresses of approximately one-half of the individuals now being recorded as syphilitic are available, there is a working basis for possible results which is a challenge to public health consciousness. Many private physicians have a sincere interest in this problem and are willing to coöperate to the fullest extent with the official agencies. Most of the blood specimens submitted to our local public health laboratory, amounting to more than 3,500 a year, not only by the clinics and hospitals, but by the individual physicians, carry the names of the patients. This frequently serves as an early lead on an infectious case.

Every private, clinical, and hospital, as well as every public health laboratory should be required to report its positive Wassermanns, precipitation tests, and dark-field examinations promptly to the nearest official health department, in addition to the responsibility of physicians in reporting the cases later. The laboratory is an important unit in the epidemiological control of syphilis. At the present time, blood specimens are submitted for examination from the great majority of suspected individuals who seek medical advice, and, except for patients with very early primary lesions, practically all cases of significance to the epidemiologist are sero-positive. During the last 3 years, a greater number of dark-field examinations have been made in the local laboratory than previously. This could be interpreted as indicating an increase in syphilis, but it is not associated with an increase in the incidence of cases reported. We believe that the public is developing a better understanding of the disease and that the great value of early diagnosis and prompt treatment is more generally recognized. Recent publicity even in the newspapers and by radio, with many favorable comments, shows a growing interest. Health officials should be

cognizant of this slow but apparent change in attitudes and make every effort to profit from it by progressing beyond the present more or less inactive statistical period to a more active epidemiological endeavor in the control of syphilis.

Some Interesting Statistics on New York City

THERE has been received from the Department of Health of the City of New York through Dr. C. F. Bolduan a small pamphlet containing some very interesting statistics on the city, and extending over a long period of years. The data show a most marked decline in the birth rate in the last 37 years. In 1898 the birth rate was estimated (figures incomplete) to be 36 per 1,000 population. In 1910 the rate was 26.95, in 1920, 23.37, in 1930, 17.64, and in 1934 the rate reached the low figure of 13.55.

The infant mortality rate (deaths under 1 year per 1,000 live births) has shown a remarkable decrease, being 140.9 in 1898, 113.38 in 1910, 85.36 in 1920, 57.24 in 1930, and 52.22 in 1934. In 1932 the rate was 50.91. Whatever factor the decreasing birth rate may be in reducing the infant mortality rate, there must have been many other factors centering in improved maternity and infancy hygiene to account for such a decided reduction.

A most interesting graph shows how the composition of the city population is changing as to its age grouping.

Per Cent of Population	1900	1910	1920	1930
Under 15 years	30.7	28.7	28.4	24.4
15 to 44 years	53.4	54.8	52.5	54.5
45 and over	15.9	16.5	19.1	21.1

The proportion of population under 15 years is now only about four-fifths what it was 30 years ago. A change might be expected in view of the decreased

birth rate. A table shows how in the last 30 years the death rates for males and females in different age groups have varied—the rates in the lower age groups showing marked decreases, for example, the rates for under 4 years is now less than one-third, for both males and females, of what it was 30 years ago.

An attractive graph covering a period of 130 years indicates how comparatively free the city now is of the epidemics which at different times swept over it, when death rates per 1,000 population at different times reached the high point of almost 50, with a general rate practically never less than 20 until the year 1895. In contrast, in recent years, even during the influenza epidemic in 1918, the death rate did not get beyond 17, and for 1934 the general death rate is 10.2.

Another diagram shows the 5 leading causes of death for a 3 year period (1932–1934) for the different age groups. The leading cause under 1 year is premature birth; 1–4 years, pneumonia; 5–9, accidents; 10–14, heart disease; then 15–19, 20–24, 25–29, and 30–34 all have tuberculosis as the leading cause; for the remaining age groups circulatory diseases stand first.

The pamphlet concludes with figures and rates for a number of causes of death for the last 30 years.

Copies of the interesting pamphlet may be obtained from New York City Health Department.

Various *Bacillus Typhosus* Antigens Used for the Macroscopic Widal

MAURICE R. MOORE, M.D., C.M.

The William W. Backus Hospital Laboratory, Norwich, Conn.

DURING the past 4 years I have observed on a number of occasions that if different Widal antigens were tested against the same blood serum, markedly different results might be obtained. Because of the confusion which these discrepancies created in my mind, I decided to compare various Widal antigens of *Bacillus typhosus* which were available on the market; also a "live" antigen and an "O" antigen.

The Connecticut State Laboratory, Hartford, and the Department of Public Health, Boston, very kindly supplied excess blood serum from their routine work which showed a positive Widal reaction. A few sera were obtained from our own laboratories.

Six antigens were used, 4 of which were purchased from leading supply houses. One of the 4 was later discontinued due to the prohibitive cost. Two were made in our laboratory; the "live" antigen according to the method of preparation employed by the Connecticut State Laboratory, Hartford; the "O" antigen according to the method used in the New York State Laboratory.

All Widal's were incubated 3 hours in a water bath at 56° C., and a reading made at the end of the incubation. They were then placed in a refrigerator over night and a final reading made the next morning. No tests were reported unless the controls were satisfactory.

The work was done by one technician

in order to have the results as uniform as possible. Each serum was tested with all the antigens, unless there was not a sufficient amount available, in which case as many as possible were set up.

DISCUSSION

The "live" antigen gave a reaction in 100 per cent of the sera of this series; the "O," 94.4, and the others varied from 78 to 85.7 per cent. This shows the number of total negative findings to vary from 0 to 22 per cent. If one accepts as a criterion that a Widal is negative if the reaction is positive to a dilution of 1:80 and negative in all other dilutions, the total number of successful reactions of antigen No. 1 were 46.4 per cent; No. 2, 34.1; No. 3, 50; No. 4, 34.4; "live," 56; "O" 47.2. This shows the number of positive Widal's to vary from 34.1 to 56 per cent—a variation of 21.9 per cent.

A comparison of the above figures reveals the same variation in results within 0.1 per cent, whether one considers the reaction at a dilution of 1:20 or 1:80.

The percentage of disagreement between the 3 hour and over night reading has a range of 35.5. This difference is more apparent than real. Fourteen times in 179 tests (7.8 per cent) the 3 hour reading was such as to have been interpreted as a negative, and the over night reading as a positive

Widal—7.8 per cent is too large a figure to be disregarded, and one must invariably wait for the over night reading before giving a negative report.

The type of floccule met throughout is tabulated in detail in the summary. I desire to comment on the similarity of the "O" and "live" antigens. The "O" gave no positives with large floccules persisting throughout and the "live" in only 2.4 per cent of the reactions. The formalin-treated antigens gave the coarse granules in 19.2 to 41.7 per cent of the tests. Antigens Nos. 1, 2 and 4 produced very fine granules in 8.8–15.4 per cent; No. 3 alone failed to give this type of floccule.

In this series of tests the "live" antigen is superior to the other antigens. The "O" is slightly less efficient than the "live" but is definitely superior to the formalin treated type. There is no doubt that a dead antigen has a decided advantage over a "live"

for smaller laboratories which are not doing the Widal frequently. The dead antigen is always available and therefore permits the reaction to be carried out immediately upon request. In contrast, the "live" antigen requires a definite interval for growth before it may be used. The "O" antigen has the advantage of being a dead antigen, and in this experiment has shown an efficiency approaching that of the "live."

One hopes that this communication may encourage the work that is being done on the "O" antigen in other laboratories. It is possible that in time the alcohol-treated antigens may partially replace the formalin-treated types.

SUMMARY

1. A total of 205 tests was done.
2. Six different *Bacillus typhosus* antigens were tested on 45 different samples of human blood serum.
3. The serum used had been previously

SUMMARY

	No. 1	No. 2	No. 3	No. 4	"Live" Antigen	"O" Antigen
Total No. of tests done.....	41	41	14	32	41	36
No. of times negative.....	7	9	2	6	0	2
No. of times the reaction discontinued at a dilution of 1:20 (questionable reactions [\pm] will be disregarded)	1	3	0	2	2	3
No. of times the reaction discontinued at a dilution of 1:40	11	6	1	7	7	6
No. of times the reaction discontinued at a dilution of 1:80	3	9	4	6	9	8
No. of times the reaction discontinued at a dilution of 1:160	6	5	2	1	7	7
No. of times the reaction discontinued at a dilution of 1:320	4	3	1	4	6	1
No. of times the reaction discontinued at a dilution of 1:640	5	4	3	2	3	7
No. of times the reaction discontinued at a dilution of 1:1,280	4	2	1	4	7	2
No. of times the 3 hour and over night reading agreed	9	13	4	14	6	3
No. of times the 3 hour and over night reading disagreed	32	28	10	18	35	33
No. of times the floccules were coarse throughout	8	7	5	5	1	0
No. of times the floccules were fine throughout..	4	4	3	5	9	7
No. of times the floccules were very fine throughout	3	4	0	4	12	9
No. of times the floccules were mixed in size....	19	17	4	12	19	18

found to give a Widal reaction with some type of antigen before being used for the experiment.

4. The number of complete failures varied from 0 to 22 per cent.

5. The positive reactions varied from 34.1 to 56 per cent.

6. The "live" antigen was the most efficient antigen used.

7. The alcohol-treated "O" antigen in this series of tests proved definitely more efficient than the formalin-treated types.

8. One considers that the type of Widal

antigen on the market should be regulated by a central authority and suggests that head of the state public health laboratories as the reasonable choice for such supervision.

NOTE: I desire to take this opportunity to thank Friend Lee Mickle, Director of the Connecticut State Laboratories, and Edith A. Beckler, Bacteriologist, Department of Public Health, Boston, for their kind coöperation in supplying me with immune blood sera. Also, I want to express my appreciation to Elizabeth P. Lathrop for her persistent care and patience in doing the technical part of the experiment.

National League of Nursing Education

THE Forty-first Annual Convention of the National League of Nursing Education (Effie J. Taylor, *President*) which was held at the Hotel Roosevelt, New York, N. Y., June 3-8, had a registration of 1,223, the largest in the history of the organization.

The meeting marked the 75th anniversary of the founding of the Nightingale School in London, England. A large mass meeting was held at Carnegie Hall to celebrate the occasion.

The entire program was centered about schools of nursing, and particularly about the reconstruction of the nursing school curriculum which is one of the chief League projects now under way. Changes which are necessary to prepare the nurse so that she may meet the needs of the changing order were discussed. These included changes in standards, educational aims, methods of instruction, curriculum structure, pattern, and content. A symposium on clinical instruction as a method of teaching was demonstrated by members of the faculty and students of Yale University.

There was a session on the control and support of nursing schools, another on ways of securing adequate clinical experience in communicable diseases, including tuberculosis, and psychiatric nursing, and nursing experience with a

public health agency. The subject of the child, the community, and the nurse was ably presented by Winifred Rand, Instructor in Parent Education, Merrill Palmer School, Detroit, and Dr. Jesse Williams, Professor of Health Education, Teachers College, Columbia University.

Among those who participated in the program were George A. Works, Professor of Education, University of Chicago; Dr. C.-E. A. Winslow, Professor of Public Health, Yale University; Dr. Willystine Goodsell, Professor of Education, Columbia University; Dr. Milton Charles Winternitz, Dean of the Medical School, Yale University; and Alphonse M. Schwitalla, Dean of the School of Nursing, St. Louis University; Isabel M. Stewart, Professor of Nursing Education, Teachers College; Nellie X. Hawkinson, Professor of Nursing Education, Chicago University; Effie J. Taylor, Dean of the School of Nursing, Yale University; Margaret Tracy, Director of the School of Nursing, University of California, and many other nurse educators.

A special feature, an innovation at the convention, was a luncheon for nursing school board and committee members.

The 1935 award of the Walter Burns Saunders Memorial Medal, given for distinguished service in nursing, was made to Adda Eldredge of Chicago.

Analysis of Public Health Expenditures by Geographic Subdivisions*

W. F. WALKER, DR.P.H., F.A.P.H.A. (*Life Member*)

*Director, Division of Health Studies, The Commonwealth Fund,
New York, N. Y.*

PREVIOUS articles dealing with current health department practices, as viewed by the sub-committee on Current Health Department Practices of the Committee on Administrative Practice, have dealt with the idea of developing a general information service, the principal sources from which information may be currently secured, and a discussion of personnel and expenditures of official health agencies in cities of various sizes. In the present article, consideration will be given to the variation in gross expenditures for public health purposes in 6 geographic subdivisions of the country and the distribution of expenditures for the principal services in these same geographic subdivisions. As has been previously pointed out, a very convenient source of information regarding expenditures and to a degree current program, exists in material filed by cities of 20,000 and over in connection with the Inter-Chamber Health Conservation Contest carried on jointly by the American Public Health Association and the Chamber of Commerce of the United States. Though the number

of cities entered annually in the Contest has varied from 108 to 276 during the 5 years in which it has been conducted, 53 cities have reported annually since 1930 through this channel in considerable detail regarding local health activities and costs.

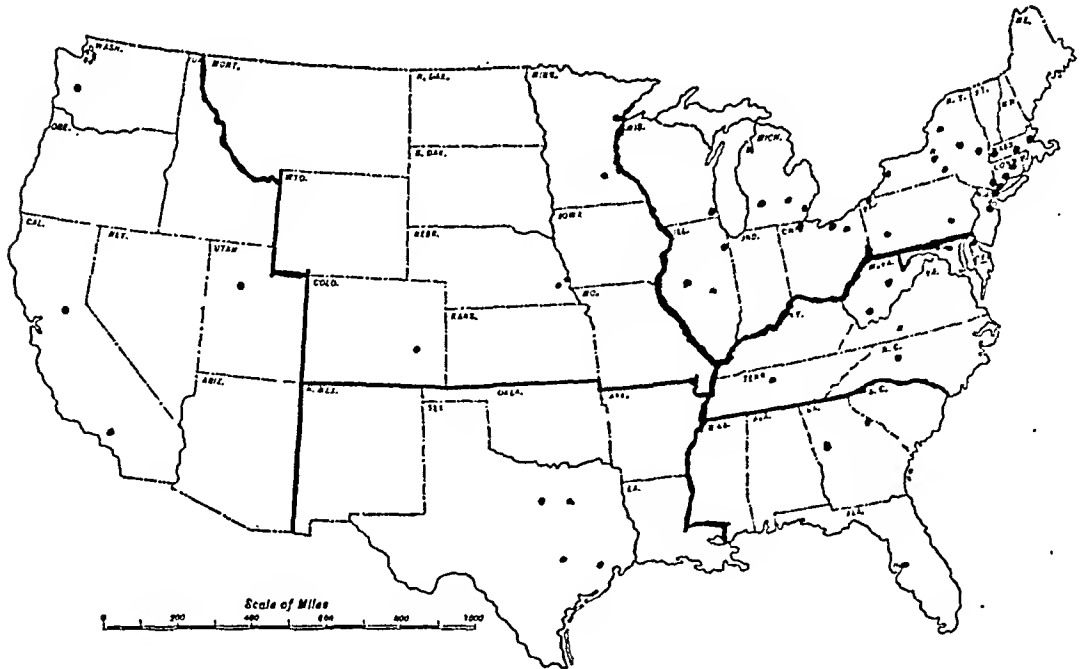

The committee in charge of the Health Conservation Contest has divided the country into 6 divisions in which it is felt the health problems are sufficiently alike to permit the grouping of experience. Figure I indicates the states included in each of these 6 divisions and the location of the 53 cities listed which provide the material for this analysis.

In Table I is shown the total number of cities of over 20,000 population in each of these geographical districts, the total population of these cities, the number and percentage of cities for which we have information concerning their experience over the 5 year period, the population of reporting cities in each district, the percentage which this population represents of the total urban population of the area (in cities over 20,000). It will be noticed that in the eastern district, the sample represents nearly 35 per cent of the total population and 17 per cent of the cities. In no instance is less than 10 per cent of the cities represented, and only in the western district does the

percentage of the urban population fall below this same figure and then to only a slight degree. While one might desire a more representative sample, in many ways the material at hand is well worth study since it is reasonably uniform and covers a critical period in our economic history.

The gross expenditures for public health services through official agen-

cies in the cities in these 6 geographic subdivisions for each year from 1930 through 1934, as well as the per capita expenditures are set forth in Table II. Here is indicated a rather interesting trend of expenditures for public health purposes. The average per capita rises appreciably for cities in the eastern, northeastern, and western divisions from 1930 to 1931 with a sharp decline in

TABLE I

NUMBER AND POPULATION OF CITIES 20,000 AND OVER, NUMBER AND POPULATION OF CITIES REPRESENTED, AND PERCENTAGE REPRESENTATION

Geographic Section	Total Number of Cities	Number of Cities Reporting	Total Population 20,000 and Over	Population Represented	Percentage Representation	
					Population	Cities
Northeastern	283	29	34,174,046	7,599,405	22.2	10
Eastern	42	7	3,666,807	1,267,879	34.6	17
Southeastern	28	3	1,778,585	431,869	24.3	11
North Central	39	5	4,113,680	905,854	22.0	13
South Central	36	4	2,787,578	769,394	27.6	11
Western	40	5	4,621,543	446,616	9.7	13
Total	468	53	51,142,239	11,421,017	22.3	11

the two succeeding years, particularly in the eastern and northeastern districts, and some indication of reviving in 1934. The point of sharp decline was a year earlier in the north central district, and the western district shows a marked early rise but gradual shrinking during the last 2 years. The average experience for the 53 cities represented using 1930 as the base year shows a 4.0 per cent rise in per capita expenditure from 1930 to 1931 and a 17.6 per cent drop using the same base to the low in 1933 and a recovery of 3.5 per cent in 1934. In considering these expenditures it needs to be borne in mind that the expenditures for the year 1930 were based on appropriations and budgets made in 1929 and that there usually is a lag of 1 year or more between expenditure trends and the local economic factors affecting them.

It is interesting to compare this general trend of public health expenditures with the criterion numbers showing the changes in the cost of living in the United States from 1922 to 1934, inclusive. This is used as the best available index of general economic conditions. Figure II shows the trend of living costs over these years as compared with the trend of health expenditures. It appears that these have been subject to the same influence. There was some delay in the effect of the depression upon the public health expenditures and a corresponding lag in recovery.

Because these figures were not available by districts, we may turn to the number of bank failures in these sections as indicating the incidence of economic shock which would affect financial stability and public appropriations. Table III, showing the bank

TABLE II

PUBLIC HEALTH EXPENDITURES AND PER CAPITA EXPENDITURES
BY GEOGRAPHIC SUBDIVISION, 1930-1934

Geographic Section	Per Capita Expenditures (Cents)					Total Expenditures (Dollars)

Exclusive of hospitalization, institutional care, medical relief, garbage collection and disposal, and capital expenditures and deficits.

Includes Board of Education expenditures, but not expenditures for physical education and health instruction by teachers.

TABLE III

BANK CLOSURES BY GEOGRAPHIC
SUBDIVISIONS, 1928-1932

	1928	1929	1930	1931	1932
Northeastern	66	95	325	874	528
Eastern	33	57	185	235	121
Southeastern	90	138	190	178	84
North Central	256	309	431	752	480
South Central	44	44	200	175	95
Western	10	16	21	80	148
Total	499	659	1,352	2,294	1,456

closures by geographic districts, indicates that the financial shock had already registered itself in the north central district in 1928 which is the same district that showed the greatest drop in expenditures in 1931. It may be significant that the western district showed few bank suspensions until 1931 and increased its appropriations up to 1933. We may expect here at least a year's lag between bank failures and their effect upon the budget.

There has been little discussion of variation of per capita expenditures by geographic districts. The highest average per capita expenditures for cities during the period under study as shown in Table II is in the northeastern district, followed by the southeastern district where the fact that only 3 cities are reporting may account for the high level indicated. The north central district, while having third highest per capita expenditure in 1930, dropped to the last place in 1934 and has the lowest average for the 5 year period. There is little evidence in these figures that the total expenditures are related to public health problems or local interest. They probably reflect more nearly the economic condition of the areas and the availability of resources, though the public concept of an adequate health program no doubt plays a part.

FIGURE II

COST OF LIVING INDEX NUMBERS, 1926-1934, AND
PER CAPITA EXPENDITURES FOR HEALTH, 1930-1934

One would naturally turn to the distribution of expenditures by the several public health functions and also by geographic subdivision, for further information as to the variation of program which would be reflected in higher or lower total expenditures. For this purpose, the expenditures for the last 2 years, 1933 and 1934, were averaged and expressed as percentage of the total budget devoted to each phase of the program. The inability of certain cities to distribute their public health nursing costs to the various services covered, and the fact that certain cities have reported a high percentage of their ex-

penditures as unallocated, makes such a comparison of doubtful value. If this information were reported on the standardized form according to uniform definitions as accurately as are causes of death—poor as they are—we would have a far more interesting and useful picture of public health administration the country over than is possible at present.

Table IV arranges the information for 1934 by size of city and appends it to material previously reported for the years since 1930. This confirms the geographic analysis which indicates a slight recovery in the per capita ex-

TABLE IV
A COMPARISON OF TOTAL AND PER CAPITA EXPENDITURES FOR HEALTH SERVICES *
BY OFFICIAL AGENCIES † FOR THE YEARS 1930, 1931, 1932, 1933, 1934

Group	Year	Number of Cities Reporting	Population Represented	Total Expenditures	Average Per Capita Expenditure (In Cents)	Maximum Per Capita Expenditure (In Cents)	Minimum Per Capita Expenditure (In Cents)

* Exclusive of hospitalization, institutional care, medical relief, garbage collection and disposal and capital expenditures and deficits.

† Includes Board of Education expenditures, but not expenditures for physical education and health instruction by teachers.

‡ In Table I (*A.J.P.H.*, March, 1935, p. 350), there appeared an error which is here corrected.

penditure in all sizes of cities except those from 20,000 to 100,000. Even in this group, the cities from 20,000 to 50,000 show an upturn from the year 1932. In the 50,000 to 100,000 group, however, the 1934 expenditure was lower than any of the preceding 4 years.

Obviously here too an accurate analysis by functions would help our understanding. It has frequently been pointed out that the use of the per capita expenditure as an index of the relative adequacy of the public health program or the comparison of different areas is subject to misunderstanding unless extreme care is exercised in the selection of items to be included as common public health expenditures. While it is believed that such care has been reasonably well exercised so far as the total expenditures are concerned in the material here reported, it is apparent that no breakdown of the material into major classes of expenditures is as yet possible. It is gratifying that

even 53 cities have been willing to coöperate through the Contest in reporting their expenditures in some detail and it would seem likely that the time has come when elementary classifications of expenditures could be set up with suitable definitions and a beginning made in the reporting of the cost of health work according to the elements of the program.

The Sub-committee on Current Health Department Practices is attempting to present the status of American health department practice as it is reflected by appropriations and personnel. It is hoped that through these series of analyses interest may be stimulated in better and more regular reporting of these elemental facts. Much still remains to be done in the way of development of definitions of services and method of recording before extensive use can be made of the valuable data which might easily be made available annually.

ANTIRABIES TREATMENT

THERE is before us¹ now the *Fifth Analytical Review of Reports from Pasteur Institutes on the Results of Antirabies Treatment*. The author, Lieut.-Col. McKendrick, is the master at this type of work. Practically every type of vaccine is considered, grouped as killed, live, heated, and other. For the general reader, the conclusions are the most valuable, while for those connected with institutions a study of the entire article is indicated. The cases considered cover chiefly those reported in 1932, and reports which reach the offices at Geneva later than May 31, 1934, will not be dealt with until the next review. While therefore the report is a little late, as far as the actual cases go, it is most valuable and informing.

Of a total of 115,859, among whom 439 died of rabies, the percentage mortality was 0.38, as compared with 0.49 in the first review, 0.48 in the second, 0.23 in the third, 0.48 in the fourth, and 0.41 over the whole period covered by the 5 reviews. These are the results, irrespective of race, method used, and other modifying factors. The review itself goes into the animal involved, the evidence of rabies in such animals, the severity and location of the injury, the protection of the bite by clothing, date of the commencement of treatment, and of other factors which might influence the results.

An interesting item is that concerning treatment paralysis. Apparently this is higher in those bitten by wolves than by any other animal, and in deep bites such as are apt to be inflicted by wolves. Those having suffered wounds of the head develop treatment paralysis more than 6 times as often as those with bites on the arm, trunk, or leg. There is not a very marked difference observed in connection with the delay in commencing treatment, though after a delay of 14 days, cases of paralysis develop somewhat more often. Paralysis followed treatment with dilutions of the cord more often than from any other preparation, and less frequently from phenol killed vaccine than other forms. From a study of

406,196 persons, the conclusion is reached that paralysis occurs after treatment with live vaccines 4 times more often than among those treated with killed vaccines, and 11 times as often as among those treated by heated vaccines.

There is a special section in the report on antirabies treatment in the Soviet Republics, 1927-1932, but the figures relate to the treatments given in 1931 and 1932. On account of delay in receiving the reports and certain other reasons, no division has been made which considers the animal, the nature of the bite, etc., so that the results apply to all types of cases. From 1927 to 1932 inclusive 310,109 persons have been treated and the mortality for successive years has been 0.23, 0.20, 0.15, 0.11, 0.14, and 0.13, showing that the rate fell rapidly from 1927 to 1929, but since that time has remained fairly constant. The numbers of those bitten by wolves were respectively 406, 153, 82, 104, 126, and 66, the deaths being respectively 35, 20, 3, 6, 6, and 7, with the mortality rates 8.6, 13.1, 3.7, 5.8, 4.8, and 10.6. It is evident that there has been a significant decline in the number of persons bitten by wolves and this has led to a fall in the general mortality, which among those bitten by dogs were respectively 0.21, 0.21, 0.17, 0.10, 0.13, and 0.1. However, the author points out that the marked decrease in the number and proportion of persons bitten by wolves is not in itself sufficient to account for the drop in general mortality.

Only 1 case of treatment paralysis is reported for the period 1931-1932, and the method of treatment in that case is not stated. Before that time the treatment paralyzes reported during the successive years mentioned were 20 in 1927, 17 in 1928, 12 in 1929, and 5 in 1930.

The results of this exhaustive study are entirely reassuring. There has been a general fall in mortality and an improvement in cases treated. Since 1930, no significant differences between the methods of treatment have been detected, though in 1927 the original Pasteur method gave results distinctly inferior to those obtained by the Högyes-Philipps method. In general it may be said that the Högyes-Philipps method gives the best results, with the Fermi, Pasteur, and Remlinger methods following in order, but the differences are now no longer significant. The whole report confirms the value of Pasteur treatment and should inspire us all with confidence in the method and with a desire to see that it is carried out in all persons bitten by animals suspected of having rabies.

INDUSTRIAL HEALTH — AN EXPENSIVE NEGLECT

IN the recent review of selected books of interest to public health workers¹ one is impressed with the spurt in new works devoted to industrial health. Has the depression given industrial hygienists more time to turn to the pen? Have new hazards or new occupational diseases suddenly appeared? With so many out of work, why the increased interest in those who remain on the job?

There is usually a basic reason for every surge in human affairs. It is also invariably economic, and, one does not have far to look to find it in the subject under discussion.

Death rates have been dropping all along the line (despite the depression), and in all age groups. However, the least noticeable change has been in the industrial population and particularly in the employed themselves, as evidenced by longevity studies, tuberculosis studies, pneumonia statistics and the rates for

so-called degenerative diseases in general. This great class of the population has not shared the recompenses of the period.

To one conversant with the situation 25 years ago, it looked as though selling the idea of industrial hygiene would be a "cinch" in America. There was European experience, particularly English, as a precedent. Big business economics alone would put it across. Insurance companies would naturally be interested (and two or three have been). Hanson in the Massachusetts Health Department, and Graham-Rogers in the New York Labor Department were speaking for leading states. Kober had published a volume under President Theodore Roosevelt's Homes' Commission. Labor organizations, of course, were primarily interested, and Hoffman was writing whole bulletins for the U. S. Department of Labor. And, as for the public, it was a protective and humanitarian necessity. It seemed that 5 to 10 years, with the collateral thrust given by the newly-created safety-first movement, would turn the trick.

There are important exceptions, of course, to any generalization, but a 25 year retrospect of industrial health in the United States really shows very little actual accomplishment, whether measured in terms of healthier conditions of work, less illness, lessened occupational disease, or lengthening of life among the industrially employed.

True, during this period much progress has been made in discoveries in this field and much has been written, but far, far too little has ever been applied. Deaf ears have largely been the recipients.

Thus, the repeated warnings against the exposure of workers to breathing mineral dusts went practically unheeded until now there is scarcely a state in the Union in which suits are not pending for the most characteristic of all occupational diseases, "silicosis"—a total in damage claims, according to some informed persons, of over 100 million dollars. It is also no defense of employers or managements to claim they were not informed of this danger since state laws recognized it back as far as the 90's with the requirements for blowers systems and proper ventilation.

It seems the cart has always been before the horse in industrial hygiene in this country, so that the deleterious effects of new methods or new substances have been first discovered in the workers themselves (as the guinea pigs) and before scientific investigations were undertaken—usually as the result of some catastrophe.

It is probably not going far astray to say that much of the lack of progress in this field has been due to political maneuvers which have cleverly diverted funds, ostensibly meant for industrial health supervision, to lay channels, and to the employment of unqualified personnel in place of *trained health workers*, not only physicians, but specialists in all fields having something to contribute to public health.

The remedy, we think, lies in better political leadership; one which can see the opportunity to do a great service to a vast part of the population; one which will capitalize, if we may put it that way, upon the idea of a higher regard for workers' lives and continued well-being; in short, one which will really motivate hygienic principles for all who work.

The problem therefore is much larger than the employer—even the big employer: it must reach the smallest work-place. It is larger than the labor union: it must reach the untrained and indeed the casual laborer. It is larger than the "average" which will "get by," since it demands specialized service.

Finally, the problem is one which demands more of the taxpayer's money in one direction—government supervision; but it will ask a whole lot less in another—the costs of neglect and dependency.

Thus, the books of the day are truly a response to the demands of the times, and a casual examination of those referred to will show nearly all are the product of matured minds and vast experiences which are speaking for human betterment.

THE BULLETIN OF HYGIENE

IN 1926, the *Bulletin of Hygiene*, a journal of abstracts, appeared, and it is not too much to say that for teachers, students, and practical health workers it has been a god-send. The auspices under which it is issued and the list of abstracters and commentators stamped it at once as authoritative. It has maintained the standards set by the first issue and one would hardly know how to get along without it now.

The history of the establishment of the *Bulletin* is interesting. The Bureau of Hygiene and Tropical Diseases, known at that time as the Sleeping Sickness Bureau, more than 25 years ago began to abstract all literature on sleeping sickness, which at that time was threatening the extermination of the populations of whole areas in tropical East Africa. The need for a central organization in London to maintain liaison between the medical officers in Africa and the investigators studying the disease at home and abroad was evident, so in 1908, the Sleeping Sickness Bureau was established. Its object was to collect all available information regarding the disease, to collate, condense, and translate this information, and to distribute it as widely and quickly as possible among those engaged in combating the disease. The first number of the *Sleeping Sickness Bulletin* appeared in October, 1908, and was followed by 39 numbers.

It became apparent that this Bureau might profitably be enlarged and its scope widened; so in 1912, the *Tropical Diseases Bulletin*, which took the place of the *Sleeping Sickness Bulletin*, was begun. It is now in its 32nd volume, and still being issued. Beginning in 1914, this Bulletin issued special Sanitation Numbers, and later Sanitation Supplements, designed especially to deal with preventive medicine in the tropics. This continued until 1926, when the Sanitation Supplements were expanded into the present *Bulletin of Hygiene*.

We wish for the *Bulletin of Hygiene* a wider circulation. While issued particularly for the benefit of British medical officers overseas, it is filled with abstracts collected from sources over practically the whole world, so that the information it contains is not local, but valuable to all workers and students in public health. The abstracts are signed, and often the abstracter comments on the high points, shortcomings, and conclusions of the articles under consideration. There are also quite frequently articles which are judicial analyses of extensive literature on big subjects which are of importance to all nations. These too are signed.

There are ten main sections which cover in order: (1) Conventions, Laws and Sanitary Regulations; (2) Public Health Administration and Social Services;

(3) Industrial Hygiene; (4) Vital Statistics and Epidemiology; (5) and (6) Port, Ship and Aviation Hygiene; (7) Food and Nutrition; (8) Bacteriology and Immunity; (9) Miscellaneous; and (10) Review of Books. We know of no other abstracts which cover as much ground and cover it as thoroughly and intelligently as do these. A feature which may be mentioned is the practical reference to volume and page of earlier numbers where earlier work is described, a great aid to the student. We wish that the book review section could be enlarged. Like the abstracts and comments, they are usually of a superior character.

It may be said frankly to our readers that the establishment of an abstract journal comparable to this has for some years been the earnest hope of some of those responsible for the *American Journal of Public Health*. So far we have not been able to interest anyone sufficiently to finance such an undertaking. We have several excellent abstract journals in this country devoted to certain specialties, but nothing which covers the ground of public health. The American Public Health Association is the body which should sponsor and direct such an undertaking. In England, the Bureau of Hygiene and Tropical Diseases, which is responsible for the *Bulletin of Hygiene*, is financed by 42 Governments, Dominions, Colonies or Protectorates. In this country our Public Health Service issues the *Public Health Reports*, but this, valuable as it is, is in no sense an abstract journal which covers the whole field of public health. Perhaps our federal government will in time realize the importance; as the English Government has done, of such a publication, or possibly some farsighted philanthropist will endow such work. Let us hope for the best, and work toward this end.

A NEW JOURNAL

IN September, 1934, there was founded the *Journal of the New Zealand Branch of the Royal Sanitary Institute*, which is to be published every alternate month. The New Zealand Branch of the Institute was formed in an endeavor to carry out in that Dominion the traditions and objects of the parent society in England, and the *Journal* has been founded to provide a means toward that end. New Zealand has many problems in field work and administration which are peculiarly its own which cannot be filled by any journal except one published on the spot by those familiar with such problems.

The first two issues are filled with interesting material of the highest order. The format is in general closely like that of the journal of the parent institute, with its seal on the front cover. We wish the new *Journal* much success, and are glad to announce that an exchange has been arranged between the *American Journal of Public Health* and our new contemporary.

THE OPEN FORUM

REGINALD M. ATWATER, M.D.

Executive Secretary, American Public Health Association

KEEPING THE RECORDS

MANY a health officer and many another administrator in the health field will thank heaven for the new volume *Recording of Local Health Work* by Dr. W. F. Walker and Carolina R. Randolph. This large book, which is published at \$2.00 through the generosity of the Commonwealth Fund, is one which promises to be of far reaching usefulness, and it may well point the way toward a desirable degree of standardization. That which the Committee on Administrative Practice has accomplished since 1920 in the general field of public health administration still remains to be done in the field of records. This is not an attempt at a review of the volume, which deserves much more adequate notice elsewhere, but is written with a desire to express appreciation for this needed compilation of practical record forms and to commend it to all field workers who have responsibility for keeping records. "It is both necessary and possible to make case records and individual service records valuable tools for the use of the local health department staff."

THE CONTESTS

FROM the viewpoint of the Central Office it has been interesting to watch the Health Conservation Contests work through to the awards for 1934 which were announced in the May, 1935, *Journal*. It is an impressive sight to see what a strong stimulus these Contests provide to health departments in cities and full-time county districts. The exhibits sent in by many of the contestants leave no room for doubt of the persistent effort that has been made to improve basic health services.

The work of the Contest Committees shows how carefully the records of the field directors are utilized in grading the contestants. The awards were finally made only after a personal check of each winning department had been made by Dr. Buck or Dr. Wallace.

Interesting too has been the use made locally of the contest for publicity purposes, and it is very certain that health department appeals for appropriations have been strengthened through these contests. Many sponsoring committees from the Chambers of Commerce have been utilizing the *Appraisal Forms* to point out weak spots, and for guidance in giving the programs proper balance. What a change has come in this country in administrative practice in the last 15 years! Yet some health officers and bureau heads are still working along in the old rut, just as though there never was an *Appraisal Form*, or a "Community Health Organization," or a record of performance elsewhere.

NATIONAL PLANNING FOR HEALTH

I AM sure that the membership will note with approval the fact that a survey of the National Health Council and its member agencies has been recently completed by Professor Hiscock of Yale. These 17 organizations in the health field are affiliated under a Council to which the American Public Health Association sends two representatives. Beginning back as far as 1921, this National Health Council has served as a clearing house for the voluntary health agencies, both the professional societies like ours and the "operating organizations." The Council has provided common services such as a library, shipping and bookkeeping

work, multigraphing service, joint office leasing, etc. With the thought that there should be more unified planning among these member agencies, this report has been prepared and there appear to be encouraging prospects. Eugene L. Bishop, M.D., President, American Public Health Association, and John L. Rice, M.D., Clarence L. Scamman, M.D., John A. Ferrell, M.D., and Louis I. Dublin, Ph.D., of the Executive Board, recently met with other representatives of Council agencies under the Chairmanship of Colonel Theodore Roosevelt, President of the National Health Council. The report by Professor Hiscock was approved in principle and referred to a Continuation Committee on which Dr. Ferrell will represent the Executive Board. The splendid possibilities for coöperative long-range planning are sufficient to make this development worthy of full support by the American Public Health Association.

PREVENTING DIPHTHERIA

HAVE you checked over the recommended procedures for diphtheria immunization as published in the *June Journal*? Are your procedures in line with these tested routines? One health officer describes the report as giving him vastly more confidence in his program of diphtheria prevention which otherwise he regards as something of a "shot in the dark."

NEW MEMBERS

MOST encouraging has been the splendid response by some state and large city health officers to the suggestion made by Dr. Parran of New York that such departments advocate the advantages of membership in the American Public Health Association through their staffs and to associated health workers. Through his own department Dr. Parran and his staff last year secured 51 new members, and this

year 47 new applications have been received from New York. Not infrequently prospective members have been found simply waiting to be asked, as though membership were open only on invitation. The advantages of association membership are evidently apparent to individuals as well as to local health departments. This office will be happy to supply application blanks, lists of present members by locality, etc., on request. Have you noted the long list of new applicants in the *June Journal*?

MEASLES CHART

I AM pleased to note that the graphic story of the usual course of measles published in this column in the May issue has proved useful to a considerable number of persons in the field. Several requests are at hand for permission to use the same line cut for reproduction. This cut will be supplied gladly in order of request.

INSTITUTE FOR HEALTH OFFICERS

APPROVAL has been expressed of the idea of an Institute for Health Officers to be held at some future Annual Meeting. What do you think?

EPIGRAMS

IT is also gratifying to note the response to the suggestion that we carry useful health epigrams and aphorisms. Several members have accumulated these for years and have enriched printed programs, annual reports, pamphlets, etc., by this means. Acknowledgment is made of those sent in, especially for the reference to the excellent compilation by Dr. James A. Tobey in the *American Journal of Public Health* for 1920, page 649. I had forgotten this list and we will add others from time to time which cannot be found in Dr. Tobey's collection.

"Health and Cheerfulness mutually beget each other"—Addison, *The Spectator*.

PUBLIC HEALTH EDUCATION*

What Have You?—What showing of child or adult health education, or of training in either direction, will you have for display at Milwaukee in October?

Scrapbooks, binders, three-dimension material, movies, slides, film slides, a play, puppets or other demonstration? Please write to the editor of this department.

Health Motion Pictures—Several 16mm motion pictures have been reported. We hope to show these and others at Education and Publicity Headquarters, Annual Meeting of A.P.H.A. at Milwaukee in October.

Who knows of other pictures produced by departments or associations?

Iowa Is No Ostrich—Newspaper and radio stations in Iowa, some of them at least, are not hiding in the sand of silence, refusing to mention syphilis or venereal diseases.

In the May, 1935, *Journal*, page 644, we put this question, "Do They Mention Syphilis?" Dr. Joseph H. Kinnaman, director, Division of Child Health and Health Education, State Department of Health, Des Moines, reports that

. . . radio stations WSUI at Iowa City, Iowa, and WOI at Ames, Iowa, permit the department and the Iowa State Medical Society to discuss the problem of venereal disease control and prevention. Both of these stations are integral parts of the two large tax supported state universities.

Dr. Kinnaman sends clippings from Sunday feature articles.

Under "Heart Disease" in *Des Moines Register*, Dec. 16, 1934:

The list of important types of heart disease includes: . . . (5) syphilitic heart disease. Syphilitic heart-vessel disease is about four times as common in men as in women. The average incidence in the United States is said to be about 10 per cent. This disease may affect the aorta (the great artery carrying blood from the left ventricle of the heart), or the coronary vessels. The prevention of syphilis, its early diagnosis and its proper treatment at the onset should greatly reduce cardiovascular syphilis.

"Getting at Germs," in the same paper, March 24, 1935:

The expert can quickly and accurately say whether or not the inflammation of the eye is caused by the organism causing gonorrhea, by other bacteria, or is not due to a germ infection. The prompt use of the direct smear followed by adequate treatment as indicated have prevented gonorrheal ophthalmia from terminating in blindness in a good many instances.

"Defenses against Disease," same newspaper, April 14, 1935:

Other preventable diseases reported to this department in 1933 include malaria, ophthalmia neonatorum (gonorrhea of the eyes of the new-born) and pellagra.

An editorial in the *Mt. Pleasant News* discusses

. . . an editorial in the *Chicago Tribune* (which) stresses the menace to society of that terrible social disease, Syphilis. Prudery can no longer keep warnings silent.

We have clippings from 7 Iowa newspapers which published the following release from the State Department of Health, entitled "The Laboratory in Disease Prevention":

Among the various tests carried out daily in public health and other laboratories, none is more remarkable than the Wassermann test. This is a serum test applied to a small amount

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evert G. Routzahn, 130 East 22d St., New York, N. Y.

of blood taken from a person or patient. In order to perform the test, other materials in definite amounts, such as guinea pig serum, rabbit serum and sheep blood are placed in small test tubes containing the specimen of human serum. When the test is completed, liquid in the test tubes is either of a clear red or cloudy color. In general, if the color is a clear red the test shows that the patient concerned is free from blood disease. On the other hand, if the tubes show a cloudy color, this indicates the presence of blood disease. The results of the Wassermann test, a well known test for syphilis, are clear-cut, striking, and trustworthy.

The Wassermann test is of value in the early recognition of syphilis. This disease not infrequently is acquired in innocent manner. Blood tests, performed routinely on a group of over 500 expectant mothers in a certain hospital, showed that 10, or 2 per cent, were infected. Adequate treatment was of untold benefit in this group, (1) in relation to maternal health, and (2) in making possible the birth of infants free from congenital disease.

The great value of the Wassermann and similar tests in disease prevention, is apparent. Without such laboratory work, disease in infants and older persons continues unrecognized and unchecked. Children who suffer from the innocent or congenital form of syphilis, bring sorrow to the home and burden to the state. Many of the mental cases in our state institutions are there through neglect on the part of society to provide for early recognition of disease. Laboratory tests, more readily available for all, represent true economy as well as a major factor in disease prevention.

"Distinctive Interpretation in 1934-1935"—Under this heading are announced the annual awards of the Social Work Publicity Council.

A committee selected from material which came to its attention 10 items which were deemed worthy of special citations. Among these were 3 from the field of public health, which was represented on the Awards Committee by Paul Komora, National Committee for Mental Hygiene.

The paragraphs which follow are from the *News Bulletin, S.W.P.C.*, 130 E. 22d St., New York, N. Y. May, 1935. 25 cents.

The Health Hunters: a series of radio

sketches for health education broadcast by the New York State Department of Health.

This is a year-round program of weekly broadcasts, in which various health subjects are colloquially and simply dramatized, to show how these subjects are woven into the everyday life of the community.

These programs are first broadcast from Station WGY, but, after the original broadcast, electrical transcriptions for reproduction are available not only to other broadcasting stations in the state, but also for use at conventions or health demonstration meetings, wherever the size or importance of the group warrants.

The sketches in this series are all set in the imaginary town of Utopia, and several characters appear again and again, giving it a good week-to-week continuity. The characters are well drawn, and the dialogue is written with naturalness. There is humor, too, and this is not a sugar-coating, but grows out of the subject matter and the characterization.

Subject Matter: A list of the subject matter shows that the broadcasts cover not only the conventional matters usually discussed in health education but seasonal matters that lie even closer to the conscious interests of communities. It is the way this subject matter is tied up to ordinary people in their everyday life that is distinctive in these broadcasts. For a Washington's Birthday broadcast: "Dr. Jones prescribes for General Washington," Dr. Jones being the character in the series which ties them all together. This sketch shows health practices and treatments in Washington's day and later developments. The sketches on mental hygiene are founded on village gossip of a type familiar to everyone, and, therefore, put these baffling problems into language easily understood. A new kind of spelling bee introduces public health terms and information.

Time: The programs are 15 minutes long. The sketch takes about 12 minutes and the rest of the time is divided between excellent interpretative introductory and concluding comment—allowing time, of course, for station announcements.

Response: The number of letters which come in as a result of the broadcasts varies, of course, depending on whether literature is offered, and on the subject matter and general appeal. The two broadcasts which brought the largest number of inquiries were Episode 70, "Bess Tries an Experiment" (235 responses), in which the women of

Utopia try living on a food budget for a week with low cost planning; and Episode 72, "A Tragedy in Utopia" (387 responses), which shows the needless death of a young woman due to venereal disease, and which points out how a lack of knowledge and the feeling that such matters should not be discussed cause untold misery. About this last program—the cause of the death was conveyed by intimation, but words "venereal disease" were used in the concluding comment, without bringing a single protest from the radio audience. (This is rather significant in view of the squeamishness of some of the networks in relation to this subject.)

The *Mother's Day Campaign for 1934*, conducted by the Maternity Center Association, New York:

One of the intriguing things about the Maternity Center campaign is the way it has ingeniously converted an event born of a beautiful but easily cheapened and artificialized sentiment into a mechanism for the achievement of a high social purpose, namely, the saving of mothers' lives. Thanks to the Maternity Center Association, under the leadership of Hazel Corbin, the Mother's Day idea has been vitalized, enriched, and rightfully enlisted in a practical and much needed health activity.

A great deal might be said of the merits and virtues and publicity values inherent in this educational project, so admirable in its conception, planning, and execution, for which credit should go to Dwight Anderson. He originated the idea and acted as consultant for the five campaigns. The directions and "specifications" are concise, practical, and complete; and the objectives presented not beyond the reach of reasonable local effort and achievement. Step by step, it builds up a simple, clear, uncomplicated design, easy to follow in even the most backward and underprivileged, not to say average, American community.

Its use of the "survey of maternity facilities" device as a preparatory basis for community action was a master stroke. It not only furnishes a pattern of action, but also the weapons and ammunition. A well stocked "publicity kit" puts at the disposal of community leaders an armory of facts and arguments drawn from comprehensive national and local surveys and studies rich in pertinent and valuable source material. It all but conducts the local campaign.

The suggested newspaper and magazine stories, conference programs, radio talks, sermons, and other forms of publicity "copy"

are all excellently prepared and "served up"—interesting, readable, and in simple diction throughout. Withal they are substantial and solid in educational content, suitable for all levels of the adult population, authoritative and enlightening, as well as persuasive, convincing, and conducive of action. The plan is sound and workable and the goals proposed are modest and realizable. The whole thing inspires confidence and expectation. It is a splendid example of planned publicity effort worthy of emulation by national agencies in other fields of public health education and interpretation.

The "Nervous Breakdown" — an article in *Fortune*:

A notable contribution to public education in the health field appearing this year is an article, "The 'Nervous Breakdown,'" published in the April, 1935, issue of *Fortune*, anonymous, as is all of the writing in this magazine.

It is an illuminating discussion, comprehensive and comprehensible, of many phases of an abstruse and complex subject—the nature, causes and symptoms of the neuroses, the main types of mental and nervous disorders differentiated according to their medical and social significance, the methods and results of treatment, the various schools of psychological thought, the scientific problems confronting psychiatric research and practice, etc., etc.—that answers many questions and clears away many of the obscurities that surround the subject in the public mind. The fact that this article appeared in *Fortune* increases its importance in that this magazine reaches the influential group of board member type not ordinarily reached by articles designed for public health education.

In the preparation of the article staff members of *Fortune* "studied and researched," and finally consulted a dozen or more men "whose names loom largest in the fields of mental hygiene, psychiatry, and psychoanalysis." Having made "the best synthesis of which it was capable," it sent copies of the manuscript to all authorities whom it had consulted. Then, following its "typical procedure" (typical for *Fortune* but unusual in general editorial practice), it corrected the errors of fact that these authorities pointed out, and where they amended, amplified or dissented, their comments were carried in liberally sprinkled footnotes.

At that, leaders in mental health work tell us that the article contains "some inaccuracies and misinterpretations," but that in the main it is "a noteworthy contribution

to public education in mental hygiene, highly valued for its fair, impartial, and substantially sound presentation of an important subject, and exceedingly helpful in the promotion of our educational aims."

Fortunately the article is to be reprinted in book form by Doubleday, Doran, available June 21, 1935.

Syphilis in Milwaukee—George A. Dundon, director of health education, Milwaukee Health Department, records that local newspapers use "social diseases." Two letters addressed to Hazel I. McCarthy, instructor in social hygiene, of the Department, present the local radio attitudes.

WTMJ, *Milwaukee Journal* station says:

We have read the copy and after giving it some consideration cannot help but feel that material of this nature is of itself so delicate that at present it would be hard to incorporate it in any radio address. Radio, like no other media of reaching the people, goes directly into the home, and unlike the printed page is heard by all who are within its range. While in the case of printed material, only those who desire, read its content. Beyond this there is also the personal side of radio, the actual voice discussing matters, which in this case would be far from a "parlor" subject. While the time may come when these subjects will not be avoided, the writer hardly feels that at present that time has arrived.

Might we suggest that you contact Mr. Theodore Wiprud, Executive Secretary of the Medical Society of Milwaukee County. Mr. Wiprud has for years been broadcasting over this station, discussing various health topics. To the best of my knowledge he has invariably stayed away from topics such as you mention, apparently considering them far too delicate for general treatment on the radio.

It seems also that the person delivering the talk might make a vast difference in the subject matter itself; by this is meant that while some outstanding authority on such a subject might be accepted in a discussion of this, an everyday commentator, or even a man of medicine not so widely known, might be severely criticised.

To sum up this answer to your letter we frankly believe that treatment of subjects of this type opens up the way to considerable discussion and that through discussion with

health authorities, etc., some means might very readily be adopted for the broadcasting of this material in a manner which would offend no one.

WISN, Hearst station says:

Relative to your recent letter regarding my point of view on whether or not a radio station should be permitted to use the word "syphilis" on the air, use of which was restricted according to the letter you sent me from William F. Snow, general director of the American Social Hygiene Association, please note:

This station has had no occasion to pass censorship upon the use of this word in any form—but I would suggest that it would be more proper to use the phrase "a social disease" instead of the word "syphilis" due to the fact that a radio station has as its audience many children of tender years, and the use of the latter word might cause considerable embarrassment to certain parents because of their inability to explain to the children if questioned. Adults would have a perfect understanding of the phrase "social disease"—while my experience with children has shown that the use of the words "social disease" causes no question in their young minds.

New Mexico Is Not Afraid—From J. Rosslyn Earp, director, New Mexico Bureau of Public Health, comes this statement:

Our New Mexico newspapers print "syphilis" either in headline or text without any hesitation. My articles on syphilis are printed just as widely as any of the others. The most popular article (judged by fan mail) that I have written was one on gonorrhea. Radio stations are equally liberal.

Unmasking "Social Diseases"—The returns, reported this month, reveal attitudes and practices in newspaper offices and radio stations in the use of "syphilis," "venereal diseases," etc.

Further reports are requested.

What About Rural Work?—In preparation for the Public Health Education Institute in October this department would like to chronicle routine

plans and practices as well as the unusual projects and materials used in smaller cities and the open country.

Who will be the first?

What To Do in Health Education
—In "An Organized Community Health Program," Savel Zimand, follows his statement of objectives with a concise review of methods. Reporting on the basis of work done in a New York City district, what follows seems to have fairly general application.

Broadly speaking, it may be said that there are three channels for public health education:

a. *Personal instruction* of individuals through the health department's staff and other professional groups such as physicians, public health and clinic nurses, and social workers and teachers, who come in direct contact with the public and are in a position to give personal advice on health matters.

b. *Small group contacts* through such community organizations as churches; Sunday and evening schools; parent-teacher associations; settlement classes; men's, women's, boys', and girls' clubs and Boy and Girl Scouts.

c. *General propaganda* by means of printed matter, public meetings, radio talks, exhibits, et cetera.

While one hesitates to give numerical values, I feel that the most valuable health education can be and is that offered by professional workers and especially private physicians and nurses who know the individuals and their home conditions and are in a position to give personal health advice. Next to this in effectiveness is the health information and knowledge given to small numbers of persons organized in special groups.

But in order to build up an informed public opinion and to secure support and assistance from the community at large, the work of these special agents must necessarily be supplemented by mass educational efforts. For measures of prevention and control of preventable diseases succeed only as rapidly as public opinion is ready to support these measures, and the general health educational activities stimulate and help to prepare public opinion.

A partial list of subjects to be stressed in a general health educational program was given earlier. While many of these subjects, depending of course on the conditions

in the particular neighborhood, should receive emphasis throughout the year, *intensive drives in certain fields* will prove an effective method to force attention and create interest in a special subject. It seems desirable to select the month for a campaign well in advance and, if possible, to arrange a time when other organizations are not planning campaigns which may compete for popular interest. These campaigns can be associated with national efforts, or form part of a community-wide drive, or, on a subject needing special emphasis, can be initiated in and limited to a certain district.

A campaign calendar will naturally vary somewhat from year to year, just as the subjects vary, for certain work can be stressed more effectively during certain seasons of the year. Intensive work on diphtheria immunization seems to yield better results after the winter months, when the epidemic of colds has somewhat abated; the early diagnosis of cases of tuberculosis during April, to correspond with similar efforts by other organizations; child hygiene, nutrition, and dental hygiene during May, to fit in with Child Health Day, or during the summer months; periodic health examinations in June or January; street safety in July and August when schools are closed and the children are more apt to be on the streets; health examinations for children in the latter part of August, and in September, before they enter school.

In *Quarterly*, Milbank Memorial Fund, 40 Wall St., New York, N. Y. Oct., 1934. 25 cents.

Health Education in the Journal, May, 1935—In "Trend in Public Health Nursing," by McIver (page 551), is a paragraph which points to a desired trend in public health education as well:

The most characteristic trend in the present public health nursing movement is the tendency toward a critical self analysis—a desire to evaluate the past and present public health nursing practices and accomplishments in terms of proven value. At no time in the history of public health nursing has there been as much available material as there is at present.

In "Specific Expenditures and Personnel of Official Health Agencies in Certain Cities". (page 545), we find

mention of administration; vital statistics; general sanitation; food, drugs, milk; child supervision; communicable disease; tuberculosis; venereal disease; and laboratory. The discussion is "exclusive of hospitalization, institutional care, medical relief, garbage collection and disposal, and capital expenditures and deficits." Otherwise there is no mention of public health education. Dr. Mountin emphasizes the difficulties encountered.

Definitions of services and fiscal practices of the health departments . . . could not always be reconciled with each other.

In "Recent Studies on Psittacosis," by Meyer, Eddie, and Stevens (page 578), we find this:

Theoretically, psittacosis is a disease which could be easily controlled, provided the public would appreciate the possible danger inherent in contact with birds, particularly those of unknown origin.

"Effectiveness of Radio in Health Education," by Turner, Drenckhahn, and Bates (pages 589-594), offers this conclusion:

The general lack of discrimination as to the reliability or unreliability of broadcast health advice shows the need for controlling health broadcasting and for instruction concerning pernicious advertising.

Here is the closing paragraph from "Public Health Education Technics of Special Experiences—Newspapers," by Higby (pages 605-608):

The copywriter of health information should so identify himself with the intangible personality which is represented by the paper for which he is writing, that when his name appears on the upper left hand corner of the copy, the editor knows he need go no further but in the rush of the day can shoot the story to the copy desk without re-write or slash. In other words, he accepts you as a member of his staff.

"What Is Public Health?" by Hill (page 622), is something we should not miss.

"The 1934 Health Conservation Contests" (pages 633-635) describes

that project of which Dr. A. J. Chesley says:

These health contests provide the most effective means available anywhere for bringing public health problems and the need for their solution forcibly to public attention, particularly locally.

At the July meeting of the Western Branch, A.P.H.A., "modern advances in health education" are to be discussed (page 640).

"The Open Forum," by Atwater (page 642), refers to the Public Health Education Institute and proposes an Institute for Health Officers.

As usual, "Books and Reports" includes background material for those concerned with health education.

"Association News" and "News from the Field" are not likely to be overlooked in view of their interest and value.

Hygeia, June, 1935—The principal articles in *Hygeia* are listed here month by month as a continued reminder of source material on popular health topics. Published at 535 N. Dearborn St., Chicago, Ill. Single copies sent free to teachers and public health workers.

Health superstitions . . . The challenge of medicine (the spirit of a profession) . . . A doctor looks at his patients . . . A man's best friends (how they helped keep him from a doctor) . . . Infancy: a frontier of science . . . Robert Koch (another pioneer scientist) . . . Aviation from the medical point of view . . . The doctor's Scotland Yard (diagnosis popularized) . . . Medical men who have loved music . . . Why the baby has eczema . . . Why worry? . . . The Black Widow (U. S. chief spider enemy) . . . Eavesdropping on the doctor (consultations reported in conversational form) . . . Eye diseases in advanced age . . . Vincent's infection or trench mouth . . . Dessert powder decisions . . . Chemists, dyes, and doctors (medical uses of dyes) . . . New books on health . . . Questions and answers.

In "School and Health Department":

Knowledge, habits and attitudes . . .
 Health teaching in June . . . Solving
 health education problems . . . Testing
 the hearing of kindergarten children . . .
 County fair features (school health aids ex-
 hibited) . . . Making children milk con-
 scious . . . New health books for teach-
 ers and pupils.

Discussion of Discussion—For the June, 1935, annual meeting of American Home Economics Association a session was announced on "The Function of Discussion in Education." A panel was to discuss:

What is the unique contribution of the discussion method and the philosophy on which it is based to the educative process? How does the symposium differ? What are the outstanding advantages and limitations of each?

The June-July, 1935, issue of *Journal of Home Economics*, Baltimore, provide a background material through an article by E. C. Lindeman on "The Place of Discussion in the Learning Process."

This department of the *Journal* urges that the P. H. E. Section and other health groups discuss discussion and other aspects of better and better meetings of health workers. Until our members and friends become "meeting conscious" we cannot make much headway in having the most useful meetings at conventions and elsewhere.

Standards for Training Health Teachers—We have the following request from a professor of bacteriology in a state teachers' college:

Has the American Public Health Association set up any standards for the training of health teachers for high schools? There is a need in the state of teachers qualified to teach health and I should like to know what is considered adequate preparation.

Any information you can give me that will be useful in preparing a curriculum for such teachers will be appreciated.

We will be glad to forward letters of suggestion.

SAFETY

"Industrial Safety," a pamphlet made up of 10 smaller booklets on industrial safety principles and their application. Metropolitan Life Insurance Co., New York, N. Y. *Free*.

"Not So Noisy But Safer and Saner." Maryland Dept. of Health, Baltimore.

"Preventing Fireworks Accidents," by Alfred E. Smith (the former Governor of New York). *Sight-Saving Review*, 50 W. 50th St., New York, N. Y. March, 1935. *50 cents*.

"Victims of Speed Mania, Unite!" by T. F. Gullixson. *Christian Century*, 440 S. Dearborn St., Chicago, Ill. March 27, 1935. *15 cents*. Appeal for limitation of speed and power of cars.

A wealth of material for various uses in classroom and in the home appears in the monthly issues of *Safety Education*, National Safety Council, 1 Park Ave., New York, N. Y. \$1.00 a year. Sample copy *free*.

FOR EDUCATION AND REFERENCE

"Concerning the Better Half of Life: Health after Forty." John Hancock Mutual Life Insurance Co., Boston, Mass. *Free*. How "the more fortunate ones learn the fine art of living. They make the second half of life the better half."

"Keeping the Well Baby Well." 8 page folder. U. S. Children's Bureau, Washington, D. C. Single copies, *free*.

"Nutrition Charts," by Bureau of Home Economics, Dept. of Agriculture. Sold by Supt. of Documents, Washington, D. C. Set of 11, black and white, 15 by 23 inches. *50 cents*.

The Nutrition Charts issued by the Bureau of Home Economics are available again in revised and expanded form. As before these charts show pictorially the results of feeding experimental diets to laboratory rats and guinea pigs. Following two charts of a general nature entitled "Growth as an index of nutrition," and "Growth may be controlled

by diet," the series shows contrasting photographs of animals that were fed on good diets and on diets deficient, respectively, in protein, calcium, phosphorus, and vitamins A, B, C, D, and G. Another chart, emphasizes the importance of iron. Each chart carries, with appropriate legend, a picture of the common foods that supply that particular food constituent, thus serving as a guide to the individual in choosing a diet to safeguard health.

A "true-false" test on tuberculosis lists 21 statements, with blanks for inserting "true" or "false." The correct answers are hidden by a fold of paper until you have tested yourself. California Tuberculosis Assn., 45 2d St., San Francisco, Calif. Enclose 3 cents. The true-false test is one of the modern examination methods which might be used more widely, especially in view of the widespread interest in information devices and contests.

The following reprints from *Sight-Saving Review* and other sources are offered by National Society for the Prevention of Blindness, 50 W. 50th St., New York, N. Y.:

"The Broad Basis for Prevention of Blindness," by Edward Jackson. 10 cents.

"The Causes and Prevention of Blindness," by A. J. Bedell.

"Community Enterprise in Preventing Blindness," by C. E. Kerby. 10 cents.

"Contribution of Statistics to the Prevention of Blindness." 20 cents.

"The Control of School Myopia," by N. B. Harman. 5 cents.

"Corrective and Protective Eye Goggles for Coal Mine Employees," by E. McAuliffe. 5 cents.

"Eye Health for Atypical Children," by L. H. Carris. 5 cents.

"Eye Hygiene at Home and at Work," by W. H. Snyder. 10 cents.

"Leisure Time Activities for Sight-Saving Class Pupils," by W. Hathaway. 5 cents.

"The Philosophy Underlying the Education of the Visually Handicapped," by G. D. Matlock. 10 cents.

"Preventing Blindness Throughout the World," by P. Lewis. 5 cents.

"The Sight-Saving Class as a Mental Hygiene Measure," by C. A. Flanigan. 10 cents.

"Trachoma in Wrestlers A Menace to Public Health," by G. M. Bruce. 5 cents.

"Your Children's Eyes," by J. R. Burke.

"Your Eyes and You," by C. A. Bahn. 5 cents.

BOOKS AND REPORTS*

Sedgwick's Principles of Sanitary Science and Public Health—By Samuel C. Prescott and Murray P. Horwood. New York: Macmillan, 1935. 613 pp. Price, \$4.25.

In 1901 the late Professor William T. Sedgwick published his *Principles of Sanitary Science and the Public Health*. It gained immediate favor and is still regarded as a classic in public health literature. It is needless to call attention to the great advances which have been made since that time in the fundamental sciences on which public health is based, and the changes which have taken place in administrative practice, the great health organizations which have come into being, and the vast amounts of money which have become available through public as well as private sources. We therefore welcome this new volume, the name of which has been slightly changed.

It has been almost entirely rewritten and much enlarged. Eight chapters have been largely rewritten; 6 have been changed as little as possible and retain much of the Sedgwick flavor, while 14 entirely new chapters have been written on subjects which were not included in the original work or else to replace some which have become obsolete, making in all 612 pages of text as against 362 in the old.

It must have required enormous courage and even boldness to undertake this revision. The authors recognized the impossibility of emulating Professor Sedgwick's style or of imitating his unusual and graphic methods of expression. Their modesty is becoming and we are glad to record our

judgment that they have succeeded to a large extent in their endeavors.

The book is practically a new one, complete, concise, and well written; but it is not Sedgwick, and we cannot advise those who are fortunate enough to possess the original text to shelve it. Both authors were students and afterwards colleagues of Professor Sedgwick. They have approached their task with reverence and with a high sense of fidelity. Even those who were not fortunate enough to be students of Professor Sedgwick know that he was unique in his knowledge and methods of presentation on all subjects of which he spoke or wrote. His lectures were so fascinating that many who were not enrolled in his courses attended them, and the writer has never met one of his students who has forgotten the impress of his personality. Such teachers are rarely met with and the man himself was one of those unusual characters who have illumined the profession.

While we find the book as a whole correct and up to date, there are certain statements to which exception must be taken. Table 4 contains not only inaccuracies, but inconsistencies. Koch is credited with the discovery of the bacillus of anthrax, though an accurate description of this organism was written by Rayer and Davaine in 1850. In 1860, Delafond cultivated the germ in blood, and in 1863 Davaine showed that normal blood would not produce the disease, while that carrying the germ described would. In the same year, Tigel and Klebs did filtration experiments showing that the filtrate of anthrax blood was innocuous while the retained portion would reproduce the disease. Koch discovered the spore and taught us much of the biology of the germ 26 years after its description was

* To locate reviews that appear in any issue of the American Journal of Public Health and The Nation's Health, consult the *Book Review Digest* in your public library.

given. In the same table the discovery of the tetanus bacillus is credited to Nicolaier. He probably saw it, although he described "cocci and divers bacilli" in the material obtained from his inoculations, and did not leave any description by which the tetanus organism could be recognized. The description of the spore form was given by Rosenbach, and pure cultures obtained by Kitasato.

Weichselbaum certainly did not discover the pneumococcus. Pasteur and Sternberg described it in 1881, and Koch made photographs of it the same year. Telamon, 1883, and Fraenkel, 1884, did sound work on it, so that in Europe it is frequently called the Telamon-Fraenkel organism. Weichselbaum, 1886, confirmed the importance of the germ described by them and added to our knowledge of it. The inconsistency lies in crediting Nicolaier as the discoverer of a germ which he probably saw but did not describe, and yet crediting Koch with the discovery of anthrax which had been seen and described 26 years before.

On page 226, the credit for proving the transmission of bovine tuberculosis to man is given to a number of people, especially to the German and English Commissions and the New York City Board of Health. As a fact, the first positive demonstration of this was given at the Laboratories of the State Live Stock Sanitary Board at the University of Pennsylvania in April, 1902. The demonstrations by the German Commission and the British Commission were at least 2 years after, and that of the New York City Board of Health 8 years later. Contrasted with this, Keefer, an American, is given credit with showing that the abortus bacillus is the cause of undulant fever in man. Why should not the same desire to credit American work to Americans be shown in regard to tuberculosis?

The chapter on Public Health As-

pects of Tuberculosis is concise and unusually good. Unfortunately it suggests that the organization of the National Tuberculosis Association was the outgrowth of the Laennec Society organized by Dr. Osler at Johns Hopkins. There does not seem to be any ground for this. Indeed both Drs. Osler and Welch were in favor of joining in with one of the two congresses on tuberculosis in existence about that time, both of which were repudiated by the new organization. While there were, no doubt, a number of factors at work, the letter to Dr. S. A. Knopf (*J.A.M.A.*, Dec. 5, 1903) was certainly the immediate and determining one.

Apart from these errors, there is little to criticise, though we believe that certified milk should have had a prominent place in the discussion of milk, since it has unquestionably done much to raise the standards.

The printing and make-up of the book are excellent, though we cannot but regret the change in format, which lessens the good flavor of the original—perhaps only a sentimental factor. Unfortunately the word "transmissible" is spelled with an "a"—no doubt due to the fact that neither of the authors was born in Boston, though they have lived there for many years, and the book is printed in New York.

We would be glad to mention especially more of the many good features of the book, but lack of space forbids. MAZYCK P. RAVENEL

Social Work Year Book, 1935—
Edited by Fred S. Hall. New York:
Russell Sage Foundation, 1935. 698
pp. Price, \$4.00.

This valuable reference work is published biennially. The present volume follows the same style and format as the 1933 *Year Book*. Part I is still "An Authoritative Record of Organized Activities," and Part II again is made up of descriptive directories of agencies

in the social field. In 1933, 836 such agencies were listed. In 1934, 990 are reported. The statistics representing the additions are interesting. The directory of national (and international) agencies contained 387 entries in 1933; 413 are listed now. The public state agencies' list of 449 is increased to 526. In the 1934 volume, 51 state-wide private agencies appear, which list is a new feature.

The Preface calls attention to the fact that the previous *Year Book* came off the press in April, 1933, 6 weeks after the Roosevelt Administration came into power. "In order to picture social work as reshaped by the momentous influences of 1933 and 1934," it is stated that all articles have been revised and mostly by new contributors. The mention of only a few of the topical articles—Public Health, Maternal and Infant Hygiene, Public Health Associations, Compulsory Health Insurance, Social Hygiene, Venereal Diseases, Health Education, Public Health Nursing—will be sufficient to indicate the interest public health workers will have in this book. The authors have been wisely selected.

This encyclopedia is a "must acquire" as a handy book of accurate information for those—and there will be many—who want a quick outline of "what is," not "what ought to be," in social work and its related fields. The *Year Book* is also invaluable in providing correct names of agencies, their addresses, the names of their executive directors, and brief sketches of their purposes and programs.

WILLIMINA RAYNE WALSH

Some Notable Epidemics—By H. Harold Scott, M.D. Baltimore: Wood, 1934. 263 pp. Price, \$4.75.

It is hard to speak highly enough of this book, not only on account of its style and character, but also because of its great usefulness. The epidemics de-

scribed are all of English origin but are none the less instructive for those living in other countries.

In the introduction the author gives his reasons for writing the book. He justifies his selection of epidemics and also his arrangement of them. The reviewer finds this very interesting and evidence of the orderly mind which has been in control of the work, but entirely unnecessary, since the most casual study shows that neither explanation nor apology is needed. We need go no further than to agree with his statement, ". . . the classical outbreaks, as we may regard them, are subjects on which all students of medical history, especially of epidemiological history, and all public health students should be informed. . . ." As the author says, he has tried to pick out the jewels from a large accumulation of medical literature and give them in a form which may interest and instruct. In this he has succeeded admirably.

He begins with the classical Broad Street Pump outbreak in 1854, the study of which—" . . . foreshadowed, almost forestalled, the bacteriological findings of thirty years later." The other epidemics analyzed follow in logical succession though not in chronological order. A typical example of this is the scarlet fever outbreak in the Parishes of St. Giles and St. Pancras in 1882, which forms a good introduction to the more widely known Hendon outbreak of 1885, which first led Dr. Power, the investigator, to suspect that the disease of cows might give rise to scarlet fever in human subjects. The outbreak at Hendon confirmed him in this view to a great extent, and it was at least proved that the disease was due to streptococci which might have been transferred from lesions of the teats to the milk by the hands of the milkers.

Those of us who are old enough will

remember the investigations of Dr. Klein, especially that in connection with the Hendon outbreak, published in a report to the Local Government Board in 1886-1887. By inoculation as well as by feeding of streptococci cultivated from human cases of scarlet fever, Dr. Klein produced characteristic symptoms, signs, and lesions of the Hendon disease.

The author of this book has done a real service to epidemiologists and students of public health, since many of these reports are difficult to obtain and all, except those fairly recent, are buried more or less deeply in official reports. While they may be found in some libraries, only a comparatively few copies are extant, and many librarians will not permit them to be taken home for study at leisure. Like most reports, they contain a considerable amount of extraneous matter from which the useful facts must be sifted. The author has done all of this work for the reader and has given all the essentials which are needed by students.

The style of the book is pleasing. It is easy to read and intensely interesting—much of it almost like a detective story, which indeed studies of epidemics resemble.

The training and experience of the author fit him peculiarly for work of this sort, and it is clear that in addition to being fitted mentally for his task, he has made good use of his opportunities. We regard the book as being necessary to every well equipped library and it should be in the offices of all health officers and teachers.

MAZÏCK P. RAVENEL

Infantile Paralysis — By George Draper, M.D. New York: Appleton-Century, 1935. 167 pp. Price, \$2.00.

Dr. Draper has presented the public with a most interesting and accurate treatise concerning our present knowledge of infantile paralysis. His style

is masterly, many of the descriptions are so impressive and so remarkably vivid that they linger long in the mind. The technical subject of poliomyelitis is clearly discussed without the employment of numerous technical terms which are so often disconcerting to the lay mind.

A short well written historical sketch is followed by a dissertation on the important subject of susceptibility, the continued study of which may some day lead us out of "the shadow of half knowledge."

Dr. Draper has brilliantly emphasized the postulate that the study of Man is essential to the study of disease. This thought permeates and enriches the entire book. Some remarkable observations are revealed in the chapter on The Nature of the Human Factor.

An impressive word picture of a case of infantile paralysis from its earliest symptoms to the end of convalescence is presented. The layman is urged to consult a physician at the onset of suspicious symptoms. Advice is also given to avoid cults and charlatans. The pros and cons of serum and vaccine therapy are discussed.

Dr. Draper's frank attitude of optimism should be most welcome and reassuring to the troubled lay mind.

Although written for the enlightenment of the layman the book contains much for the edification of the physician and medical student.

J. VERNON LUCK

Tuberculosis and the Negro in Pittsburgh — By Elsie Witchen. Published by the Tuberculosis League of Pittsburgh, 1934. 120 pp. Ill. Write the Tuberculosis League of Pittsburgh, 2851 Bedford Avenue, Pittsburgh, Pa., for a free copy.

This booklet presents the findings of the 2 year Negro health survey made by the Tuberculosis League of Pitts-

burgh. The primary objective of this study was to determine the prevalence of tuberculosis among the 55,000 colored residents of Pittsburgh but in addition much valuable information was obtained on other health problems of the Negro as well as on such important factors as housing, nutrition, occupation and economic status.

In all 8,385 persons, or 15 per cent of the city's Negro population, received a complete physical examination. An indicated case rate of 8 per cent for all forms of tuberculosis and 4.5 per cent for the active adult type of pulmonary disease in the city's Negro population brings out the gravity of the problem which not only concerns Pittsburgh but other northern cities with a large number of colored residents.

The problem is still further complicated by such factors as low economic status, poor housing and poor nutrition. Of the 3,616 persons of employable age attending a clinic, 60 per cent were unemployed, while 105 tuberculous patients slept in rooms with three or more people.

This study should be read by everyone who is interested in the health problems of the Negro.

C. ST. C. GUILD

Recording of Local Health Work—

By W. F. Walker, Dr.P.H., and Carolina R. Randolph. New York: Commonwealth Fund, 1935. 276 pp. Price, \$2.00.

All those who have attempted to devise a satisfactory system of records for a health department know how difficult a task it is. There are the practical, day-by-day uses of the forms for administrative and supervisory purposes to be considered. There are aspects of record keeping important to individual staff members. There are more remote statistical uses of records which sometimes are distorted into such

a prominent position that they seem exclusively important. To maintain a fair balance between these uses is no mean task. Fortunately the many-sided contribution of a committee has been made available in this compilation by Dr. Walker and Miss Randolph, and the work reflects a well balanced judgment in this complex field.

In his foreword to the volume, Dr. Eugene L. Bishop points out from his own experience that the use of a uniform record system by a state has every advantage and no disadvantage: "If uniformity could be extended beyond state boundaries and the same items could be reported under the same terminology throughout the entire country, the usefulness of the collected information would be immeasurably increased."

The authors have included discussions of record keeping with illustrative forms which will save many hours to those who may wish to recast their forms or their systems in accordance with this plan. Simplification and accuracy will follow the adoption of these forms, all of which have been tested in actual use.

The volume may be commended to all having to do with record systems, their design and operation, as well as their interpretation. A distinct service has been rendered to all administrators of the public health. Especially noteworthy will be the advantage to those who study current health department practices and who have felt the imperative need for just such a standard work of reference.

The final chapter is one which should be read by every worker before compiling an annual report or a statistical statement, for it condenses much practical wisdom and contains a summary of standards for the graphic presentation of facts set up by the American Statistical Association. How much more

useful and clear our reports would be if we all adhered to this set of standards!

Special appreciation is due to the Commonwealth Fund for making this expensive publication available generally at a nominal cost. CARL E. BUCK

The Doctor's Bill—By Hugh Cabot, M.D. *New York: Columbia University Press, 1935.* 313 pp. Price, \$3.00.

This volume is a significant addition to the current publications in the field of medical economics. The author, who was formerly on the faculty of the Harvard Medical School and later Dean of Medicine at the University of Michigan, is now a consulting surgeon on the staff of the Mayo Clinic. Not many medical clinicians have the breadth of social vision which Dr. Cabot shows in this study nor the willingness to face the facts so well substantiated in the recent surveys. The reader catches the spirit of an intelligent man honestly seeking the truth and essentially free from either a professional prejudice or a prior commitment to a particular solution.

As President Lowell of Harvard points out in the introduction, this book should be read not only by physicians but as well by laymen who are interested in these important aspects of personal and public health, for the author discusses the problem "with an open mind, not hesitating to criticise the

medical profession for its shortcomings, its lapses into a commercial attitude, and its lack of interest in the larger aspects of its potential functions."

Those familiar with Dr. Hugh Cabot's teaching methods will recognize his pungent style and all will find the text very readable.

Even physicians have had considerable difficulty in seeing the whole field. They are, and must be, from the very nature of their calling, intense individualists. To them Medicine still retains—thank God—some of the qualities of a religion. They take fright at the thought that profane hands may soil the Temple of their God—Service. At this point emotion is likely to come into action—and understanding goes out the door. Furthermore, they have a very real vested interest which it would not be human in them to disregard. Often enough in their opposition to change they have failed to grasp the implications of the profound economic and social changes which have been going on about them. As a result, on too many occasions they have fought a series of futile rear-guard actions which have left them still on the defensive.

The bibliography is excellent, with full reference to the important studies of European experience in this field of socialized medicine, and the text shows that the studies of others have been used in the process of stating the conclusions of one very thoughtful doctor. It is the hope of American Medicine that men with Dr. Cabot's leadership in the profession will see as clearly and take their stand as uncompromisingly.

REGINALD M. ATWATER

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Farm-City Migration Declines—City-ward migration declined about 16 per cent in 1934, and farm-ward migration about 18 per cent. 994,000 persons left cities for farms, and 783,000 left farms for cities. Due to the higher birth rate, the farm population is still gaining, however.

ANON. The Farm Situation. Bur. of Agric. Econ. 19; 5:1-5 (May), 1935.

First Quarter Mortality Relatively Low—The mortality of industrial policy holders of the Metropolitan Life Insurance Co., during the first quarter of 1935 was at a record low point, viz., 9.4 per 1,000 (annual basis). Tuberculosis was down 5.1 per cent from last year. Among other diseases which showed lower mortality than last year were cardiac, cerebral hemorrhage, acute nephritis, syphilis, and cancer. Suicide was down 11.5 per cent, and automobile accidents, 6.0 per cent.

ANON. Stat. Bull. Metropolitan Life Ins. Co. 16, 4:3-5 (Apr.), 1935.

Sources of Information in Vital Statistics—Especially valuable to the casual user of vital statistics.

Ibid. pp. 6-8.

What Proportion of Twins Are "Identical"?—About a third, according to the methods of deduction used by geneticists.

Ibid. pp. 8-9.

Our Changing Health Problems—Mortality from the common infectious diseases is less than half the rate of 30 years ago, and some have virtually

disappeared. Among the problems of today the more important are: diseases of the older ages, automobile accidents, appendicitis, and puerperal causes of death.

ANON. Quart. Bull. Dept. of Health, New York City 3, 2:21-23 (no date), 1935.

How Many Diabetics?—The Department of Health of New York City is undertaking to get an answer by taking a census through physicians. The *a priori* estimate is 100,000.

Ibid. p. 39.

Mortality Causes Contributory to Diabetes—A valuable table by age and sex. Not often seen.

Ibid. p. 44.

Typhoid Agglutination—The majority of cases of typhoid fever with no history of previous vaccination develop both H and O agglutinins, although in a few instances one type alone may present. The elimination of negative sera by a microscopic technic is recommended as a preliminary procedure to titration with the formalized H and alcoholized O antigens.

BOLE, R. Value of H and O Agglutination Technic in Routine Widal Examinations. J. Lab. & Clin. Med. 20, 6:638 (Mar.), 1935.

Comparative Tuberculosis Rates—Tuberculosis in children has decreased at a more rapid rate in Minneapolis than, for instance, in Gothenburg, Sweden, where BCG has been used to immunize children. The types of the disease causing the greatest number of deaths in Minneapolis were tuberculous meningitis, pulmonary and

miliary tuberculosis. Lymph-node and bone tuberculosis are a negligible cause of death.

BOYNTON, R. E. The Declining Death Rate from Tuberculosis in Children. *J.A.M.A.* 104, 21:1875 (May 25), 1935.

Bacteriologists and Epidemiologists, Attention—A quicker method of identifying the diphtheria bacillus than by using Loeffler's medium is described, and its possibility in identifying suspected carriers is discussed.

BRAHDY, M. B., *et al.* A Rapid Method for the Identification of Diphtheria Bacilli. *J.A.M.A.* 104, 21:1881 (May 25), 1935.

Concerning Our Blissful Ignorance in Nutrition—Concluding that one of the difficulties in the realm of nutrition is not obtaining a balanced diet, but the retention of a balanced outlook on diet, this wholesome paper reminds us of the many things we do not know about nutrition. Would that this skepticism might be more frequently preached on this side of the Atlantic.

CATHCART, E. P., and HUTCHINSON, R. Nutrition and Public Health. *Pub. Health* 48, 8:286 (May), 1935.

Typhoid in the Navy—Among the 895,680 navy personnel vaccinated against typhoid fever during the past 10 years, there were only 73 cases of typhoid fever. As would be expected, the navy typhoid rate has shown a marked reduction since the prophylactic measure was adopted, greatly accelerated over the civilian rates for the disease.

COOK, S. S. The Efficacy of Typhoid Prophylaxis in the United States Navy. *U. S. Nav. M. Bull.* 33, 2:169 (Apr.), 1935.

What Children Yell for—Only once in a long while do we find a really new idea. The children in this ward of a hospital are served whatever they want to eat in whatever quantities they ask for. The results will astonish nu-

tritionists, parents, child psychologists, and you. It would be a shame to annotate this paper which all should read.

DAVIS, C. M. Self-Selection of Food by Children. *Am. J. Nurs.* 35, 5:403 (May), 1935.

Acute Rheumatism Hereditary?—The incidence is higher among children if a parent is affected, than if both parents are unaffected. Apparently susceptibility depends upon hereditary factors. Environmental factors also appear to be indispensable to development of the disease.

FRASER, J. A., and ROBERTS, W. A. R. Family incidence of acute rheumatism. *Annals of Eugenics.* London. VI, Pt. I (Oct.), 1934.

Welcome to the Armadillo—Relapsing fever is more prevalent than is usually suspected (because of failure to use diagnostic facilities) in the Southwest. It is a disease enjoyed by man and the armadillo in addition to opossums, squirrels, and chipmunks.

GILLESPIE, J. O. Relapsing Fever in the United States. *J.A.M.A.* 104, 21:1878 (May 25), 1935.

Tuberculosis in School Teachers—In Minneapolis, school teachers and other school employees were examined for tuberculosis. Six open cases were discovered and many others presented lesions of the reinfection type. The educational opportunities presented by the examination were not neglected. That the procedure is not universally applied is a reflection on our public health consciousness.

HARRINGTON, F. E., *et al.* Tuberculosis Among Employees of the Minneapolis Schools. *J.A.M.A.* 104, 21:1869 (May 25), 1935.

Poliomyelitis Virus from Healthy Carrier—In connection with the effort to explain the recognized widespread immunity to poliomyelitis, an attempt was made to detect the virus of the dis-

ease in tonsils and adenoids from persons with no history of contact with cases. In one instance, tonsil and adenoid tissue from a 2-year-old child produced poliomyelitis in monkeys.

KRAMER, S. D. Detection of a Healthy Carrier of Virus of Poliomyelitis without History of Contact. *Proc. Soc. Exper. Biol. & Med.* 32, 7:1165 (Apr.), 1935.

International Epidemiologic Data—The "Weekly Epidemiological Record" of the League of Nations will henceforth include not only pestilential diseases but also those common in temperate climates. The bi-monthly Bulletin will in the future appear quarterly. The current issue calls attention to epidemics of cerebrospinal meningitis in the Anglo Egyptian Sudan, Japan, and parts of India.

Correspondence, and Epid. Report, League of Nations 177 (Jan.-Mar.), 1935.

Visualizing Communicable Diseases—A device is described to display a cumulative record of reported communicable disease cases to show comparisons with expected incidence.

OLESEN, R. A Communicable Disease Meter. *Pub. Health Rep.* 50, 21:702 (May 24), 1935.

Depression Ill-Health—Another report of an extensive illness survey which shows the effect of unemployment upon morbidity rates. Those hardest hit suffered the greatest increases in disabling illness. Analyses of the gross findings will appear in succeeding papers.

PERROTT, G. ST. J., and COLLINS, S. D. Relation of Sickness to Income and Income Change in Ten Surveyed Communities. *Pub. Health Rep.* 50, 18:595 (May 3), 1935.

Antibodies in Antimeningococcus Serum—Using Miller's mucin method for stabilizing the virulence of strains of meningococci, antimeningococcus sera have been tested for the presence of protective antibodies. Two

methods were used: Varying dilutions of serum were employed or the time varied between the inoculation of the culture and the injection of a constant amount of serum. Polyvalent and homologous sera gave very nearly equal results, with a slight advantage for the polyvalent serum. Some slight protection was obtained with heterologous sera.

RAKE, G. A Method for Titrating the Protective Action of Antimeningococcal Serum. *Proc. Soc. Exper. Biol. & Med.* 32, 7:1175 (Apr.), 1935.

Venereal Disease Control—Discussing the measures to be applied in New York City for an attack upon the venereal diseases—including medical, epidemiologic and educational projects—the suggestion is made that a special time be set aside, like the early diagnosis campaign for tuberculosis, for special and intensive propaganda against gonorrhea and syphilis.

RICE, J. L. Public Health Aspects of a Venereal Disease Program for New York City. *New York State J. Med.* 35, 10:533 (May 15), 1935.

Adult Immunity to Diphtheria—A comparison of adults who had, and had not, received antitoxin in childhood indicates that the childhood injections may have had some influence upon adult immunity, but that this influence can be outweighed by other factors. The degrees of immunity found among adults varied greatly.

SUGG, J. Y., *et al.* The Individual as a Factor in Antidiphtheria Immunity. *Am. J. Hyg.* 21, 3:562 (May), 1935.

Storage of Water Samples—Behavior of bacteria in stored water samples is dependent not only on the temperature of storage, but it varies with the particular strains of bacteria present. After 48 hours in the refrigerator (0°-7° C.) the number of viable organisms had varied but slightly from the original. Icing of samples as

provided in Standard Methods is desirable.

TANNER, F. W., and SCHNEIDER, D. L. Effect of Temperature of Storage on Bacteria in Water Samples. *Proc. Soc. Exper. Biol. & Med.* 32, 6:960 (Mar.), 1935.

Controlling Yaws—Although American sanitarians have for the most

part only an academic interest in yaws, this statement of the possibilities in control through case finding, treatment, and follow-up as demonstrated in Jamaica will be found to be a statement of epidemiologic principles of more general application.

TURNER, T. B., *et al.* Yaws in Jamaica. *Am. J. Hyg.* 21, 3:483 (May), 1935.

ASSOCIATION NEWS

MILWAUKEE TRIPS OF SCIENTIFIC INTEREST

Milwaukee Auditorium Arena

GUESTS of Milwaukee at the 64th Annual Meeting of the American Public Health Association, October 7 to 10, will find a variety of places of scientific interest to visit. Dr. John P. Koehler, Commissioner of Health and General Chairman of the Local Committee, has an excellent sub-committee on inspection trips at work on this feature of the program.

There will also be boat trips and other entertainment typical of Milwaukee, including visits to the famous breweries, to the Carnation Milk Company plant at Oconomowoc, a tea at Milwaukee-Downer College for women, a drive through the county park system, to certified dairy farms, and to the beautiful housing development at Kohler.

Many health workers will be interested in the new Matthew Keenan Health Center, a \$200,000 gift to the city. This center concentrates offices for existing health department services on the northwest side where they may be better utilized by the general public and private physicians. Its services include: consultation and diagnosis in chest conditions, X-ray examinations, immunization clinics for diphtheria, smallpox, typhoid fever, and scarlet fever; two dental clinics for indigent children; eye, ear, nose and throat diagnosis and consultation, and child welfare clinics. The center is also headquarters for northwest side field nurses and sanitary police.

Milwaukee has a \$13,000,000 sewage disposal plant which is reputed to be

one of the pioneer activated sludge plants to be put in operation. It occupies an area of 58 acres, has a capacity of 160 million gallons daily, and serves a metropolitan district of 152 square miles with approximately 112 miles of main and intercepting sewers.

The Milwaukee County institutions are located just west of the city and include an infirmary, a 1,000 bed county hospital, asylum for chronic insane, hospital for mental diseases, home for dependent children, Muirdale Tuberculosis Sanitarium, and Bluemound Preventorium. These institutions occupy a tract of 1,100 acres which is beautifully landscaped and arranged. Another one of the county buildings, the Dispensary-Emergency unit, is located near the center of the city.

The Bluemound Preventorium is the only institution of its kind in Wisconsin

and medical experts agree that it is doing the most effective anti-tuberculosis work in the state. It comprises ten buildings and cottages, and has been called Milwaukee's nearest approach to a nudist colony—a pair of trunks being the regulation uniform of the children it houses. Only two of the 1,900 children who have been cared for at Bluemound Preventorium in its 9 years of work have later been obliged to enter Bluemound Tuberculosis Sanatorium for treatment.

The Milwaukee Vocational School, just across the street from the convention headquarters in the Auditorium, is one of the first and foremost schools of this type in the United States. The school occupies an entire city block, is valued at \$5,000,000, and contains several hundred classrooms. It has two auditoriums, one of which seats 2,000

The Milwaukee Sewage Disposal Plant

Blue Mound Preventorium, Milwaukee

people. There are 202 faculty members, and nearly 30,000 students. Among the 203 courses offered, there is academic instruction for about 400 student nurses being trained in the city's hospitals, and industrial rehabilitation work is conducted for crippled students and those injured in industry.

Milwaukee-Downer College is one of the outstanding, accredited women's colleges of the country. In addition to

other courses, it offers degrees in nursing and occupational therapy. The occupational therapy course requires 5 years of academic work with 9 months of practise training, and leads to a Bachelor of Science degree.

The new Marquette University Medical School is located within walking distance of hotels and the Auditorium. It has an interesting display of pathological specimens, and the building is

One of Milwaukee's Certified Milk Farms

Milwaukee County General Hospital

part of a health unit, embracing the physical education department, a dental school with a 150 chair clinic, the student health service, and an eye, ear, nose and throat hospital and clinic. Dr. Eben J. Carey, Dean of the Medical School, will be recalled as the director of medical exhibits at the Century of Progress exposition in Chicago.

A trip is being arranged to the Milwaukee Children's Hospital Convalescent Home 10 miles west of Milwaukee. This is a 50 bed institution made possible by gifts of charitable Milwaukeeans, one of whom donated the \$250,000 building and 80 acre grounds. It is a unit of Children's Hospital, and provides ideal facilities for long-time cases requiring rest and expert care.

Milwaukee also boasts the largest municipally owned museum in the country. It is located near the Auditorium and has a magnificent collection of historical relics and scientific curios. The Milwaukee Museum is famous for its early American characterization. Among the case exhibits special mention should be made of the "Old Time

Pharmacy" and the botany halls. As Milwaukee claims to be the birthplace of the typewriter, visitors will enjoy the typewriter exhibit being developed.

Visitors will also be welcomed at the new \$10,000,000 Milwaukee County Court House and administrative building which is located just three blocks from the Auditorium on an elevated site which overlooks the central business district.

The city's new \$5,000,000 water purification plant is now under construction on the shore of Lake Michigan, and by October may be in shape for the inspection of delegates to the convention.

Milwaukee has 9 fresh air rooms, and also schools for handicapped children. Among these is the Lapham Park School for Crippled Children which houses 140 youngsters, of whom about 60 are infantile paralysis cases.

It also conducts, through the Department of Health, 27 child welfare clinics, and numerous preschool clinics in cooperation with various women's organizations.

One more feature worth mentioning is that Wisconsin, as a rule, has its most delightful weather in the fall, and an opportunity will be offered to visit some of its hundreds of lakes, resorts,

and natural beauty spots, many of them near Milwaukee. The Wisconsin Dells, located northwest of the city, is one of the country's outstanding scenic attractions.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Franklyn B. Amos, M.D., State Department of Health, Albany, N. Y., Epidemiologist-in-training
 Calvin C. Applewhite, M.D., M.P.H., State Board of Health, Columbia, S. C., Surgeon, U. S. Public Health Service
 Bellfield Atcheson, M.D., 1111 Roosevelt St., Gary, Ind., Health Commissioner
 George E. Atwood, M.D., D.P.H., Waycross, Ga., County and City Commissioner of Health
 Louis Bonfield, M.D., 1870-75th St., Brooklyn, N. Y., Medical Inspector, New York City Department of Health
 Smith A. Combes, M.D., 131 Fulton Ave., Hempstead, N. Y., Health Officer
 Joseph B. Garlick, M.D., 1113 State St., Schenectady, N. Y., Commissioner of Health
 Robert B. Harkness, M.D., Charlotte, Mich., Director, Eaton County Health Department
 J. Frederick Kenzie, M.D., Prattsburg, N. Y., Health Officer, Consolidated District
 Edward L. Kingman, M.D., Newtown, Conn., Health Officer
 David L. Lieberman, M.D., Chester, Conn., Health Officer
 N. Stanley Lincoln, M.D., Mt. Morris, N. Y., Superintendent, Mt. Morris Tuberculosis Hospital
 Bryan Newsom, M.D., C.P.H., 300 Public Safety Bldg., Seattle, Wash., Assistant to the Commissioner of Health
 Charles M. Pearce, M.D., State Dept. of Public Health, Oklahoma City, Okla., Commissioner of Health
 M. A. Rogers, M.D., 75 Main St., Greenwich, N. Y., Health Officer
 George W. Ross, M.D., Port Ewen, N. Y., Health Officer
 Rafael Schiaffino, M.D., Sarandi 283, Montevideo, Uruguay, S. A., Director, Division of School Health
 Theodore H. Sills, M.D., 866 Main St., Newington, Conn., Health Officer
 Harry B. Smith, M.D., M.P.H., Town Hall, West Hartford, Conn., Superintendent of Health
 W. M. Talbert, M.D., Dept. of Health, Decatur, Ill., City Physician

Laboratory Section

Rosemary Bole, M.A., State Dept. of Health Laboratories, Columbus, O., Bacteriologist
 Henry E. Cope, M.D., 1551 D. Whitney Bldg.,

Detroit, Mich., Pathologist, Delray General Hospital
 Ferdinand C. Helwig, M.D., St. Luke's Hospital, Kansas City, Mo.
 Alfonso Jaramillo-Arango, M.D., C.P.H., Carrera 8a 439, Pereira, Colombia, S. A., Public Health Officer
 Marion H. Lippman, M.D., Rm. 609, Butler Bldg., 135 Stockton St., San Francisco, Calif., Clinical Laboratory Director
 Virginia Mix, A.B., 724 W. Magnolia St., Stockton, Calif., Bacteriologist, San Joaquin Local Health District
 Grace Mooney, B.A., 99 Linden St., New Haven, Conn., Research Assistant in Public Health, Yale University School of Medicine
 Howard J. Shaughnessy, Ph.D., State Dept. of Public Health, Springfield, Ill., Chief, Division of Laboratories
 Dixie M. Woodburn, A.B., Imperial County Health Dept., El Centro, Calif., Laboratory Technician

Vital Statistics Section

Florence G. Babcock, University Hospital, Ann Arbor, Mich., Record Librarian
 George W. Baehne, 270 Broadway, New York, N. Y., Manager, Institutional Dept., International Business Machines Corp.
 John F. Cadden, M.D., State Capitol, Charleston, W. Va., State Registrar of Vital Statistics
 Thomas W. Chamberlain, 10 Municipal Courts Bldg., St. Louis, Mo., Deputy Registrar, Bureau of Vital Statistics
 Sterling S. Cook, M.D., Dr.P.H., Bureau of Medicine and Surgery, Navy Dept., Washington, D. C., Charge of Division of Preventive Medicine
 Ralph C. Fletcher, M.A., 425 Olympia Rd., Pittsburgh, Pa., Director, Bureau of Social Research
 William McK. Gafafer, D.Sc., 185 Glenwood Ave., Leonia, N. J., Research Associate, U. S. Public Health Service
 William S. Groom, 34 W. 6 St., Cincinnati, O., Board Member, Cincinnati Public Health Federation
 Florence G. Hardy, A.B., 209 Pine St., Harrisburg, Pa., Statistician, State Dept. of Health
 Hill Montague, Jr., M.A., Life Insurance Company of Virginia, Richmond, Va., Statistician
 Jason Waterman, U. S. Public Health Service, Washington, D. C., Collecting and Com-

piling for Publication Statistics of Notifiable Diseases

Public Health Engineering Section

- Louis H. Dreier, 1947 North Ave., Bridgeport, Conn., American Sewage Disposal Co.
 Stanley Markey, A.B., 318 S. Cherry St., Eaton, O., Sanitarian, Preble County Dept. of Health
 William F. O'Connor, Jr., Ph.D., 106 Bellevue Pl., Yonkers, N. Y., Research in Sewage Disposal and Professor of Chemistry
 B. P. Rice, State Board of Health, Columbia, S. C., Sanitary Engineer Inspector
 James R. Simpson, B.S., Box 319, Blacksburg, Va., Research Fellow in Sanitary Engineering, Virginia Polytechnic Institute

Food and Nutrition Section

- Justo F. Gonzalez, M.D., Calle Paysandu #1282, Montevideo, Uruguay, S. A., Professor of Hygiene
 Emanuel Kaplan, Sc.D., 2525 Brookfield Ave., Baltimore, Md., Chief, Division of Chemistry, City Health Department
 F. Arnold Todd, D.V.M., C.P.H., 98 Park St., New Haven, Conn., Student, Yale Dept. of Public Health

Child Hygiene Section

- James E. Drake, M.D., 533 Sharp Ave., Spokane, Wash., Health Supervisor, Public Schools
 Julia C. Foley, B.S., Box 13, Rockville, Md., School Nurse
 Josephine Rera, M.D., 1146-58 St., Brooklyn, N. Y., Child Hygiene Division, New York City Dept. of Health
 Viola W. Whiteside, 137 Louvre Blvd., New London, Conn., School Nursing Division, City Health Dept.
 Eugene B. Wilson, M.D., State Dept. of Health, Albany, N. Y., Assistant Director, Division of Orthopedics

Public Health Education Section

- Roy T. Cowing, B.S., 43 Garden St., West Springfield, Mass., Student, Yale University School of Public Health
 Daniel H. Deyoe, M.D., Niskayuna, N. Y., Epidemiologist-in-training, State Dept. of Health
 Mary E. DuPont, R.N., 23 Main St., Bradford, Pa., Executive Secretary, McKean County Tuberculosis and Health Society
 Charles McDowell, M.D., 310 Kenmore Pl., Brooklyn, N. Y., Professor of Physiology and Public Health, New York Homeopathic Medical College and Flower Hospital
 Carlos E. Paz Soldan, M.D., Union Boza

#876, Lima, Peru, S. A., Professor of Hygiene, University of Lima

- James Steele, M.D., 98 Monitor St., Brooklyn, N. Y., Chairman, Williamsburg-Greenpoint Advisory Council and Medical Advisory Committee to the New York City Dept. of Health
 William F. Van Buskirk, M.S.P.H., State School for Boys, Meriden, Conn., Assistant Superintendent

Public Health Nursing Section

- Helen G. Ross, R.N., Broadalbin, N. Y., Staff Nurse, Fulton-Montgomery Health District
 Clara B. Hamilton, W. Va. State College, Institute, W. Va., School Nurse
 Agnes V. Murphy, 11 Nassau St., Boston, Mass., Assistant Director, Visiting Nurse Service, John Hancock Mutual Life Insurance Co.
 Kathryn C. Trent, Box 250, Charleston, W. Va., Director, Health & Nutrition, W. Va. Relief Administration

Epidemiology Section

- Miriam Brailey, M.D., Dr.P.H., 710 N. Broadway, Baltimore, Md., Instructor in Epidemiology, School of Hygiene and Public Health, Johns Hopkins University
 Robert E. Hickey, M.D., Rm. 608, City Hall, Milwaukee, Wis., Director of Communicable Disease Division, City Health Dept.
 Nels A. Nelson, M.D., Rm. 546, State House, Boston, Mass., Assistant Director, Division of Communicable Diseases, State Dept. of Public Health
 Edward C. O'Brien, M.D., Rm. 25, Municipal Courts Bldg., St. Louis, Mo., Epidemiologist, Division of Health, Dept. of Public Welfare
 Leslie T. Webster, M.D., 66th St. and York Ave., New York, N. Y., with Rockefeller Institute

Unaffiliated

- Ralph Horton, M.D., N. Y. State Tuberculosis Hospital, Oneonta, N. Y., Superintendent
 Leo C. Mundy, M.D., 391 Scott St., Wilkes-Barre, Pa., Medical Relation Board, Luzerne County Medical Society
 Frank A. Wilcox, M.D., 415-16 St., West New York, N. J.

DECEASED MEMBERS

- Mae E. Mathers, R.N., Ashland, Va., Elected Member 1934
 Lucy Minnigerode, R.N., Washington, D. C., Elected Member 1924
 Mrs. Joseph Sanders, Washington, D. C., Elected Member 1933

NEWS FROM THE FIELD

MARYLAND CONFERENCE OF HEALTH OFFICERS

ON MAY 31-June 1 there was held in Baltimore a very well attended Conference of Health Officers under the direction of Dr. Robert H. Riley, F.A.P.H.A., Director of the State Department of Health.

Maryland is a state very favorably situated for such a conference with the resources of the Johns Hopkins School of Hygiene and Public Health available, and full use was made of these and of the Baltimore City Department staff. The State of Maryland has succeeded in attracting a very well trained group of health officers and other personnel in its system of county health units which now embraces every county in the state with full-time service.

Speakers at this conference from other states included Dr. Henry D. Chadwick, Commissioner of Public Health of Massachusetts, Dr. Stanley Osborn, of Connecticut, Dr. E. A. McLaughlin of Rhode Island, Dr. R. A. Vonderlehr, Dr. Milton V. Veldee, and Pearl McIver of the U. S. Public Health Service, Dr. George C. Ruhland of Washington, D. C., Dr. W. A. McIntosh of the Rockefeller Foundation, and Dr. Reginald M. Atwater, Executive Secretary of the A.P.H.A.

CANADIAN NATIONAL HEALTH CONFERENCE

FOUR Canadian health organizations held a combined conference in Toronto June 3, 4, and 5 with a large and representative attendance from all parts of the Dominion. The Canadian Public Health Association held its twenty-fourth annual meeting at this

time and with it were combined the Ontario Health Officers' Association, the Canadian Tuberculosis Association, and the Canadian Social Hygiene Council. This grouping of agencies with much of mutual interest was reminiscent of meetings of the American Health Congress of 1926 in which many of the groups affiliated in the National Health Council met together. These associations have so much in common that it is not surprising that the occasion resulted in stimulating meetings of each group and of the groups as a whole for the consideration of matters of general interest.

In addition to the many members and Fellows of the A.P.H.A. from Canada who were in attendance, the American Public Health Association was represented by Dr. Eugene L. Bishop, President, who was on the program, Dr. John A. Ferrell and Dr. Clarence L. Scamman of the Executive Board, and Dr. Reginald M. Atwater, Executive Secretary. Dr. H. E. Kleinschmidt of the National Tuberculosis Association also spoke on "Modern Medicine's Promise to Abolish Tuberculosis."

The Canadian Public Health Association has chosen Vancouver, B. C., as the place of the next meeting which it is hoped to hold in conjunction with these same organizations and in addition with the Western Branch of the A.P.H.A. and possibly the Canadian Medical Association.

3-CENTS-A-DAY HOSPITAL PLAN

ON MAY 7, Fannie Hurst, the novelist, became the first subscriber to New York's new 3-cents-a-day plan for hospital care. Meetings are

being held throughout the city to discuss the plan with the speakers sent out by the United Hospital Fund, which is sponsoring the service.

Groups of at least 10 persons, half of whom must be employed or gainful workers, may join. No one more than 65 years old will be accepted. Applications are accepted from groups of New Yorkers or suburbanites living within 50 miles of the city.

While in the hospital, members are entitled to 21 days of semi-private care if needed, which includes bed and board, general nursing care, routine laboratory examinations, ordinary X-rays, use of the operating room, routine medications and dressings, and all other customary routine services which may be prescribed by the doctor. Maternity hospital care is also included after the patient has been a member of the plan for 10 months.

The benefits are available immediately in cases of accident or emergency illness, and after 10 days from the date of the first monthly subscription payment for other illness.

INSTITUTE OF GOVERNMENT

THE Seventh Annual Institute of Government was held, June 10 to 14, in the School of Government of the University of Southern California, Los Angeles. Among the subjects considered were Hospital and Institutional Management, Public Health, Public Welfare, and Water Supply and Sanitary Engineering. Walter H. Brown, M.D., F.A.P.H.A., President-Elect of the A.P.H.A., and Abel Wolman, C.E., Life Member, A.P.H.A., served on the Faculty.

JULIUS ROSENWALD FUND

AT the annual meeting of the Julius Rosenwald Fund in Chicago, May 19, \$284,000 was appropriated for the work of the year beginning July 1. The appropriations were for rural education,

medical services, and Negro welfare. The Fund will maintain a staff of 12 teachers and students who will work with schools in the southern states in an effort to give education a more direct bearing upon life in rural communities.

It was announced that the Fund will continue its active interest in health insurance, pay clinics, public health, and other organized services which will make good medical care more available to people of small incomes. Dr. Michael M. Davis is Director of the Fund's medical division.

NEW OFFICERS OF CONNECTICUT PUBLIC HEALTH ASSOCIATION

THE Secretary of the Connecticut Public Health Association reports the following new officers elected at the meeting of that organization held on May 15 at Bristol.

President—B. B. Robbins, M.D., Bristol

Vice-President—Louis J. Dumont, M.D., New Britain

Secretary-Treasurer—Ira V. Hiscock, New Haven

Board of Directors

D. C. Y. Moore, M.D., South Manchester

F. W. Wersebe, M.D., Washington

B. N. Pennell, D.V.S., New London

Marion Douglas, R.N., Hartford

Edward Schneider, Ph.D., Middletown

Milo P. Rindge, M.D., Madison

Albert E. Austin, M.D., Greenwich

Stanley H. Osborn, M.D., Hartford (ex-officio)

Raymond D. Fear, M.D., Stamford (ex-officio)

Representative on Governing Council of A.P.H.A.—Louis J. Dumont, M.D., New Britain

Alternates—Millard Knowlton, M.D., Hartford; Albert E. Austin, M.D., Greenwich

RESEARCH ASSOCIATES OF M.I.T.

FORMATION of the Research Associates of the Massachusetts Institute of Technology, a group of leaders and organizations in business and industry who will contribute to the financial support of important research, was disclosed by Dr. Karl T. Compton,

President of the Institute, at the reunion dinner of Technology alumni on June 3.

The new organization, which has a founder membership of 21, was created in recognition of the threefold value of research in stimulating leadership among members of the faculty; as a method of teaching students to apply their resources of knowledge; and in developing new discoveries with far-reaching social benefits in industry, health, safety, standards of living, and intellectual satisfaction.

The formation of the Research Associates marks the beginning of the second phase of a successful experiment which began 6 years ago when the Rockefeller Foundation made a substantial grant to permit the institute to demonstrate the value of an active program of research in the basic sciences of biology, chemistry, geology, and physics.

CAPPS PRIZE AWARDED DR. GULBRANDSEN

THE Joseph A. Capps Prize for 1934 of the Institute of Medicine of Chicago has been awarded to Lars F. Gulbrandsen, member A.P.H.A., instructor in bacteriology and public health at the University of Illinois College of Medicine, for work and his paper on "Invasion of the Body Tissues by Orally Ingested Bacteria and the Defensive Mechanism of the Gastro-Intestinal Tract." The prize of \$500, established by an anonymous donor in honor of Dr. Joseph A. Capps, is awarded annually for the most meritorious medical research by a graduate of a medical school in Chicago completed within 2 years after graduation.—*The Diplomat*, 7, 5:180 (May), 1935.

DR. STEVENSON HAS RETIRED

A COMMUNICATION from England indicates that letters from the United States are still addressed to Dr.

Stevenson as Medical Statistical Officer of the General Register Office of England. It will, therefore, probably be of interest to many readers to know that Dr. Stevenson has retired, and has been succeeded in office by Dr. Percy Stocks.

SAN FRANCISCO MORTALITY AND DEPRESSION STUDY

THE studies of health and the depression by the U. S. Public Health Service and the Milbank Memorial Fund are being continued in a white collar work project involving a house-to-house canvass of 30,000 families in San Francisco, in coöperation with the California State Emergency Relief Administration. The purpose of this survey is to determine the mortality among the families of the unemployed as compared with families of the employed wage earners, with particular reference to changes in the death rate during the depression years, 1929-1934. A. W. H.

F.E.R.A. NURSING WORK IN GEORGIA

PERHAPS the most important asset in development is the fact that all F.E.R.A. nursing work is under the direction of Abbie Roberts Weaver, whose knowledge, ability and experience insure work and goals of the highest feasible standards.

A state Child Health and Welfare Council has been organized and wherever possible local branch councils have been organized. Also there is a State Public Health Committee of the Georgia State Medical Association. This, of course, immediately secures the participation, interest, and backing of the lay public and the medical profession.

For the first time in its history, Georgia has public health nursing service for every county, the F.E.R.A. supplying this where local agencies cannot. As counties are very small, some nurses carry 3 counties.

The staff consists of: 1 state-wide

supervisor, 6 district field supervisors, 62 child hygiene nurses, and 10 tuberculosis nurses. The program includes:

1. Prenatal service
Visits and classes
2. Infant care
Instruction, group conferences, and child health clinics
3. Care of the preschool child
Instruction, clinics, conferences, arrangement for treatment when necessary
4. Immunization
Typhoid, diphtheria, smallpox (under direction of a physician)
5. Promotion of birth registration
6. A survey of crippled children and their needs
Organization of crippled children's clinics and securing treatment for them
7. Supervision of midwives in coöperation with the State Department of Health
8. Tuberculosis work in the promotion of clinics, supervision and education of patients, and obtaining treatment for them
9. Coöperation with official and non-official agencies in promoting infant and maternal welfare.
10. Assistance has been given to a special committee of the Georgia State Medical Association in making a study of maternal deaths.

Emphasis in the total program is placed on prenatal, infant, and preschool phases of public health work, and tuberculosis work.

Bedside care is given only as a demonstration.

While the above services are primarily for families on relief, they are open to other families, when eligible, at the request of physicians.

It will be seen that F.E.R.A. in Georgia has a broad, comprehensive program, built upon sound principles of public health and well coördinated with the State Department of Health and the State Medical Association. No doubt this will mean tremendous development for Public Health work in Georgia.—Helen Bond, R.N., Director, Health Center, Savannah, Ga.

X-RAY-RADIUM CONGRESS IN MEXICO

THE Latin American Congress of Physical Therapy, X-ray, and Radium will hold its first annual meeting in Mexico City from August 29 to September 5. The National University of Mexico will act as host to their North American colleagues, and the government will participate in extending hospitality to the delegates.

To facilitate the attendance of American physicians, a 19 day convention cruise has been arranged for physicians, members of their families, and friends. In coöperation with the American Express Company, five special tours to the Congress have been arranged, the S. S. Yucatan having been especially chartered for the first of these. It will also be possible to go both ways by rail, or to go one way by steamer and return by rail.

For information, address Dr. Cassius Lopez de Victoria, 1013 Lexington Avenue, New York, N. Y.

DR. ROSENAU RETIRES

MILTON J. Rosenau, M.D., since 1909 Charles Wilder Professor of Preventive Medicine and Hygiene at Harvard University, will retire this year. Dr. Rosenau is 65 years of age.

He was graduated from the University of Pennsylvania School of Medicine in 1889 and pursued graduate work at the Institute of Hygiene in Berlin, the Pasteur Institute in Paris, and the Institute of Pathology in Vienna. He was a surgeon in the U. S. Public Health and Marine Hospital Service from 1890 to 1909.

At the Indianapolis Annual Meeting of the A.P.H.A., in 1933, the Sedgwick Memorial Medal, for distinguished service in public health, was awarded to Dr. Rosenau—

... on the basis of Dr. Rosenau's long and fruitful career in the field of public health, for his remarkably successful 10 year administration of the Hygienic Laboratory of

the U. S. Public Health Service where he carried out pioneer investigations on anaphylaxis, for his practical work on disinfectants and on the pasteurization of milk, for his numerous original contributions to bacteriology and epidemiology, for his wise and inspiring participation in coöperative research upon influenza, pneumonia, and poliomyelitis, and especially for the service rendered public health workers throughout the world by his classic book *Preventive Medicine*.

Dr. Rosenau has been a member of the A.P.H.A. since 1909, and is a Charter Fellow.

NEW YORK HEALTH OFFICERS AND NURSES

THE Annual Conference of Health Officers and Public Health Nurses was held at Saratoga Springs, N. Y., June 26-28.

The New York State Association of School Physicians and the American Association for Hygiene and Baths met at the same time.

COMMUNICABLE DISEASES IN NEW YORK

A HEAVY increase in the number of cases of communicable disease handled during the first 4 months of 1935, as compared with the same period in 1934, is noted in a report of the Henry Street Visiting Nurse Service. In this period the Henry Street nurses cared for 1,944 communicable disease patients, among a total of 39,688 cases of all types. The figures for the same period a year ago show 1,112 communicable disease patients in a total of 38,538.

The chief reason for the increase is the fact that 1935 is a especially severe measles year. The nurses cared for 819 measles cases in the period covered as against 60 cases in the same period last year. Other figures are: 352 cases of scarlet fever, as against 256 in the same period last year; and 128 cases of whooping cough as against 79.

Fifteen or 20 years ago, the safety of taking care of communicable disease

patients in the home was considered questionable. Today, however, the visiting nurses are demonstrating every day, by following out careful technics developed through years of experience and approved by the Medical Advisory Committee and the City Health Department, that children may be cared for safely at home. Under the supervision of a visiting nurse, the family of the sick person also learns a great deal about disease control and becomes an important agent in the prevention of disease in the community.

Only 12 cases of diphtheria were recorded by Henry Street nurses, as against 23 cases a year ago, the reduction being attributed to the intensive drive for inoculation against this disease conducted by the City Health Department in coöperation with the Henry Street Visiting Nurse Service and other organizations.

ARKANSAS PEDIATRIC SOCIETY ORGANIZED

THE Arkansas State Pediatric Association was organized at a meeting in Little Rock, March 6. In addition to pediatricians, physicians especially interested in the care of the child may enjoy the clinical privileges of the society through associate membership.

The first annual meeting of the society was held April 15, during the meeting of the state medical society. Officers are Drs. Morgan Smith, chairman, and Madeline A. M. Melson, Secretary.—*J.A.M.A.*, April 27, 1935.

BLOOD DONORS' BUREAU

THE Providence Medical Association has established a bureau for professional donors of blood, at Providence, R. I. All donors have negative Wassermann reactions and normal hemoglobin and are in good physical condition.

Calls are handled through the Physicians and Surgeons Exchange. Dr.

Francis H. Chafee is chairman of the committee that established the service.

DR. FLEXNER RETIRES

DR. SIMON FLEXNER, Director of the Laboratories of the Rockefeller Institute for Medical Research since the opening of the Institute in 1903, has presented his resignation, to take effect on the appointment of his successor. He is 72 years of age. . . .

Dr. Flexner has contributed extensively to the literature on bacteriology and pathology, especially on epidemic cerebrospinal meningitis and its serum treatment; poliomyelitis, its cause and mode of transmission, and epidemic encephalitis. He, with his collaborators, was the first to use the meningococcus antitoxin. He was chairman of the U. S. Plague Commission in 1900, a lieutenant colonel in the Medical Corps of the U. S. Army from 1917, and in 1919 became a colonel and Assistant Surgeon General of the U. S. Public Health Service. In 1923 he was chairman of the Public Health Council of New York.—*J.A.M.A.*, 104, 25:2274 (June 22), 1935.

PERSONALS

CHARLES V. CHAPIN, M.D., emeritus superintendent of the Providence, R. I., Health Department, was given the Susan Colver Rosenberger Medal, the highest honor which Brown University can bestow upon an alumnus. The Award was established in 1919 and is made from time to time "for especially beneficial or notable achievement." Dr. Chapin is an Honorary Charter Fellow of the A.P.H.A.

BRIG.-GENERAL M. A. DELANEY, Assistant Surgeon General, U. S. Army, and Commandant of the Medical Field Service School, Carlisle, Pa., was the recipient of an honorary degree, Doctor of Science, from Dickinson College, Carlisle, Pa., at the

152nd Annual Commencement, June 10. General DeLaney is a member of the A.P.H.A., and was until recently Adviser in Public Health to the Governor-General of the Philippines.

RACHEL K. MILLER, R.N., member A.P.H.A., formerly with the Oakland (Calif.) Health Department, is now organizing and directing the S.E.R.A. public health nursing program in San Bernardino County, Calif., with headquarters in San Bernardino. She writes that this county has the largest area of any in the United States. It is approximately the area of the State of South Carolina.

DR. CLYDE B. HUTT has been appointed to take charge of the city-county Health Department at Vancouver, Wash., succeeding Dr. Robert W. Armstrong, resigned.

C. LEROY EWING, member A.P.H.A., Director, Bureau of Laboratories, Baltimore City Health Department, was recently elected President of the Maryland Society of Bacteriologists.

C.-E. A. WINSLOW, Dr.P.H., Fellow and Life Member of the A.P.H.A., of Yale University, was reelected President of the Connecticut Society of Mental Hygiene at its 27th annual meeting in Bridgeport, Conn., held May 20. This was a joint meeting with the Bridgeport Society of Mental Hygiene, which was holding its 11th Annual Meeting.

DEATHS

WILLIAM HENRY GUILFOY, M.D., Registrar of Records in the Department of Health of New York City for 29 years until his retirement in 1930, died on May 23. He was 75 years of age. The first person to take a competitive civil service examination in New York State, Dr. Guilfoy was appointed a medical clerk in the Department of Health in 1885, and served for 45 years. He gave up his work of keeping the city's vital sta-

tistics because of poor health, but recovered and regularly visited the offices of the department. He became ill a week before his death. While associated with the Department, Dr. Guilfooy saw the death rate of the city decrease from 28 per 1,000 to less than 12. He also saw the attitude of the public toward vaccination and other health measures change greatly.

DR. C. ST. CLAIR DRAKE, managing officer of the Jacksonville (Ill.) State Hospital, died on June 2 of heart disease, after a long illness. Dr. Drake entered the state service in 1912, and served until Governor Lowden's term expired. He became Associate Field Director, under Dr. Walker, of the Committee on Municipal Health Department Practice (afterward changed to the Committee on Administrative Practice) of the A.P.H.A. in June, 1925, and continued in that capacity until March, 1928. In that year he again entered the service of the State of Illinois under Governor Emmerson. Dr. Drake was a member of the Association since 1914.

MRS. WILLIAM LOWELL PUTNAM, prominent social welfare worker of Manchester, Mass., died on June 6. She was active during the War and spent large sums of money conducting a bureau of soldiers' information in Boston. In November, 1917, she was appointed by the Red Cross Casualty Bureau as the official representative from Massachusetts in Paris and Washington. Mrs. Putnam, among other positions, has been vice-president of the Household Nursing Association, member of the council of the National Child Welfare Association, and president of the American Association for the Study and Prevention of Infant Mortality. She was a member of the A.P.H.A. since 1915, and a Life Member since 1929.

CONFERENCES

July 1-3, Annual Meeting of the Montana State Medical Association, in conjunction with Sixth Annual Meeting, Western Branch American Public Health Association, Helena, Mont.

July 1-3, Sixth Annual Meeting, Western Branch American Public Health Association, Helena, Mont.

July 15-20, Royal Sanitary Institute Health Congress, Bournemouth, England.

July 16-20, Fourteenth International Housing and Town Planning Congress, London.

July 22-27, Seventh International Congress on Industrial Accidents and Diseases, Brussels, Belgium.

July 23-27, International Congress on Life Assurance Medicine, London.

July 31-Aug. 3, Annual Meeting of the American Dental Society of Europe, London.

Aug. 8-19, Fifteenth International Physiological Congress, Leningrad and Moscow, Russia.

Aug. 9, 10, North Pacific Pediatric Society, Seattle, Wash.

Aug. 10-17, Meeting of Health Section of the World Federation of Education Associations, Oxford, England.

A Permanent Type of Ditch Construction

ALFRED H. FLETCHER, F.A.P.H.A.

Sanitary Engineer, Department of Health, Memphis, Tenn.

MEMPHIS has carried on an intensive malaria mosquito control program for 15 years and all money budgeted for this work has been spent on the control of the *Anopheles* breeding in the ditches and bayous. A total of approximately \$140,000, excluding administrative and premise inspection costs, has been expended by the city during the years 1920 to 1934 inclusive, starting with an allotment of about \$4,000 a year for a city of 24.3 square miles and a population of 162,351; and increasing to an allotment of about \$13,000 a year for a city of 48.2 square miles and a population of 268,358. Until 1930, this money was expended solely for oiling all ditches once every 10 days, or as nearly every 10 days as is possible, with a small amount of ditching and cleaning of water courses during off seasons. In 1930 a small cooperative experimental project of lining about 1,000 feet of ditch with concrete was carried out at the suggestion of J. A. LePrince, with the U. S. Public Health Service furnishing the material and the city furnishing the supervision and labor. All of this ditch is still intact and is satisfactory as a concrete lining. This experimental project was installed in sections using

different mixes and thicknesses to determine the most economical for general use in Memphis.

In ditching for malaria mosquito control, the ideal section of ditch is V shape with a narrow U shape center ditch within the larger main ditch. Flat bottoms, especially of dirt or in concrete culverts encourages meandering flow with frequent dams and pools. Permanently lined ditches with sodded banks prevents the ditch from scouring deeper, wider, and irregularly, eliminating the every 10 day routine oiling work. Repeated regrading, cleaning, and oiling of unlined earth ditches has proved a constant and endless task. Properly lined and stabilized ditches show a greater first cost, but are ultimately less costly and far more effective as a control measure. The maintenance cost of the ditch is practically eliminated, which in this day of intensive public building, is a very important point to a city. The problem of flood control and elimination of erosion and loss of public and private property, are other important benefits realized. With this in mind, in the C.W.A. ditching work in Memphis and later in the E.R.A. work, the concrete lining of ditches was stressed.

FIGURE I—Royster Bayou through a residential section at Galloway Avenue and Avalon Street, before work was done

J. A. LePrince, known to all yellow fever and malaria control workers for his outstanding leadership in this field from the first campaigns in Havana, Cuba, and the Panama Canal, to the present time, has been urging and assisting the Memphis Health Depart-

ment in this work which promises to broaden and make far more effective our malaria mosquito control program.

Out of the rush and tension of our C.W.A. struggle to accomplish as much as possible with a large force of men with hastily selected and untried or un-

FIGURE II—Same as I after lined with broken concrete pieces for walls and bottom with cement grouting and sodded banks

tested relief supervision, with adverse weather conditions and with the problems of getting labor and materials, transportation and equipment to mesh in together, approximately 6 miles of 18" concrete lining was placed in the bottom of straightened ditches. An effort was made to sod and stabilize these concrete lined ditches as the work proceeded, but only approximately 2 miles of the 6 was sodded.

In all cases, without exception, where the concrete lining was installed and the banks were sodded, there were no failures and no follow-up repair work was necessary. Sodding should in all cases immediately follow the completion of the concrete lining. In other words, with a concrete lining by itself without protection such as is afforded by sod at the edge of the concrete lining, the swift flowing water in the narrow bottom of the ditch will erode the banks and undermine the concrete lining. Erosion may also be caused by water running down the bank from the top and forming little channels which will eventually cause erosion, especially at the edge of the concrete lining. Except in special cases, this erosion can be prevented by the use of Bermuda sod. In addition, sharp bends, tree roots and other obstructions cause eddies and churning and hence are important points to protect by removing or by special treatment to prevent erosion. A comparison of unit cost of concrete or rip-rap or sod when used to stabilize the banks of the ditch above the central concrete lining, indicates that with the use of sod, there is no material cost, while with the use of rip-rap and cement grouting, the material cost is 1 cent per sq. ft. and for concrete the cost is about 10 cents per sq. ft. In addition to protecting the sides and the bottom of the ditches to prevent erosion, it is advisable to incur additional expense in many cases to straighten the ditches, as this pro-

vides for quick run-off which is beneficial from a flood control standpoint and at the same time minimizes the erosive action of the water as it goes around the sharp bends.

LOCATION AND DESIGN

A preliminary survey by walking over the existing ditch will determine whether any changes should be made in the course or line of the ditch. If any changes are considered advisable or necessary, a more detailed survey of the ditch and territory adjacent to the existing and the proposed new location should be made to determine the location of the ditch, property lines, houses, culverts, sewers, water pipes, etc. A map and profile should be drawn showing the actual location and elevations as well as a map and profile of the proposed ditch together with the elevations of all underground piping. In some cases the property lines will govern largely the course of the ditch, and in all cases easements should be secured from the owners of property affected by the changes.

The grades, dimensions of section, the location and the course or line of each ditch depend on the drainage area or watershed it serves. This area has already determined or influenced the size, grade or elevation and location of bridges and culverts through actual field data and calculations, or through estimates based on experience when this data is not available. Subdivision developers have changed the course of drainage oftentimes in order to lay off as many lots as possible. After selling these lots to many individuals, some of whom build soon after their purchase, it soon becomes impossible to straighten or change ditch locations even though they may follow a crooked course around lot corners and buildings. It is important, however, to study the possibility of changing the existing zig-zag course of many ditches to a shorter,

1. Minimum of 18" bottom. 2. Limits of slopes: Minimum $\frac{1}{2}$ to 1. Average 1 to 1. Maximum $1\frac{1}{2}$ to 1. 3. Three or 4 culverts or bridges should be used in establishing necessary area of ditch. In going down stream area should never decrease but increase according to increased run-off.

straighter ditch and also wherever possible to eliminate the sharp bends which interfere with the flow of water in the ditch and create eddies and scouring.

In designing the proper section of ditch for the concrete lining with sodded banks, certain limiting values are used. The most satisfactory slope used in Memphis is a $1\frac{1}{2}$ horizontal to 1 vertical. The minimum width lining is 18". The area of the lined ditch should be greater than, or equal to the area of the culvert it receives its water from, if this culvert or bridge is built to carry a definite run-off already figured for the ditch. In other cases a number of culverts and bridges should be measured and the size of ditch figured to carry at least the volume of water now carried by the existing structures. In all cases, if possible, a uniform section should be kept throughout the length of each ditch. In general, linings should be U shape to carry the dry weather flow. In wide ditches a narrow U shape section can be installed in the center with sloping rip-rap sides for the rest of the width

of the ditch. The maintaining of a uniform grade and section will minimize changes in velocity and the resultant dropping of sediment and thus prevent the forming of dams and leaving pools of water.

Table I has been computed as a guide in deciding on the proper width and slope of concrete lined ditches. In many cases, however, the actual width of a ditch may necessitate a wider bottom than shown in the table. The table is used only as a guide and to insure that all V shaped lined ditches are large enough to carry the run-off.

EXCAVATIONS

Grade and slope stakes should be set for the rough or preliminary excavation. On straight ditches the stakes should be set 50' apart, on curves about every 25' or less, and on sharp curves about 10' apart. Cutting to these stakes will bring the ditch to within a few inches of the finished ditch. Better alignment and a more satisfactory completed ditch from all standpoints can be obtained if a trench the width

FIGURE III—Section of Madison Heights Bayou looking north toward Jefferson Avenue.
Note: Caving frame supports an old shed before much work done.

of the bottom of the ditch is dug to line and grade and then the sides sloped rather than try to do sloping

along with the other excavation. This does not apply to large ditches where "step excavation" is the best pro-

FIGURE IV—Same as III after lined with rip-rap and banks sodded

cedure. At this point the final grade stakes should be reset to finish the excavation. The top of the center line grade stake should be driven to the concrete finish grade, and the side and slope stakes should also be set to the concrete finish grade. The side stakes, that is, the ones at the outer edge of the concrete lining should be set about 6" above the center line stakes on the 18" and 24" lining. The ditch bottom is cut to 2" or 3" (the thickness of the concrete lining) below the top of the stakes. This final excavation should be done by experienced ditchers to insure a uniform bottom to grade so as to have uniform thickness of concrete. If the lining is too thin it is weak: if it is too thick it wastes concrete and money; if nails are driven into the top of the stakes and a cord pulled taut between stakes, it assists in cutting a uniform width and depth, and the cords can be used also as a guide in placing the concrete. The outside of curves is elevated just as is done in building a highway.

CONCRETE LINING

In mixing the concrete for the lining, a few fundamental rules should be observed to get the best at the least cost. A lean mix and as thin a lining as will last is, of course, the most economical. We are now using a 2" thick lining with a 1:3:5 mix using a minimum amount of water just to make the mix workable to keep the water-cement ratio low. The 18" lining has about a 6" drop from the edges to the center line. When possible to buy or borrow a concrete machine mixer, the work can be speeded up.

If the mixer is placed halfway between, or say 200' on long stretches from the upper end of the ditch and enough material placed at this point to complete the whole stretch or the first 400', time will be utilized to best advantage in not having to handle the

material and equipment any more than is necessary. The ditch would be poured from the upper end to the downstream end. If the mixer is a large one, two laying crews can be used, with each crew laying 200' in two sections at the same time.

A chute can be arranged to slide the concrete direct into wheelbarrows from the mixer. Runways placed on the bottom of the ditch, consisting of 2" boards will prevent the cutting or muddying up of the ditch bottom, as the concrete is wheeled down the ditch to where it is being placed. A thin lining should not be poured on a muddy bottom. Although expansion joints were not used in much of the C.W.A. lining work and there have been no subsequent failures, we are now using about 6 sheets of 2 ply tar paper for joints about every 50'.

On steep grades, especially where the lining is placed on a fill, or where for any other reason the water might be allowed to run under the lining, key walls about every 200' should be built at right angles and extending under the lining into a solid foundation to stop the flow of water with weep holes on the upstream side to provide outlet for the water after the rain, to seep up onto the lining. (See sketch of key wall).

In some cases where sod was not immediately placed at the edge of the lining, scouring was worse when the edge of the lining was rough. If the sod was immediately placed, the rough edge did not seem to cause any scouring.

CHART I—Sketch of Key Wall

FIGURE V—Section of Madison Heights Bayou looking north toward Court Avenue before cleaning and rip-rap work done

Forms can be used without losing much time making it possible to get a smooth edge. Care should be taken to prevent any honeycombing of the concrete

at the edge and the top edge is being slightly rounded.

Even though the lining is not usually subjected to any great pressure, the

FIGURE VI—Same as V after lining bottom and sides and sodding banks

lining should not be allowed to dry out for a day or so, especially in the dry weather, in order to cure properly and prevent scaling off, pitting, or disintegration later on. No reinforcing has been used. As already emphasized, the sod should now be laid on the banks without delay.

SODDING

In sodding, the operation is divided into two steps with a sod cutting and loading crew of 8 to 10 men and a sod laying crew of 2 to 3 men. Sod is cut in strips of approximately 10" x 12" x $\frac{1}{2}$ " to 1" thick. Only thick and pure Bermuda sod is used. If $\frac{1}{2}$ " to 1" thick sod is cut and laid, the roots will grow 2" within a few weeks and thus get a firm bull-dog grip on the bank and withstand heavy flood rains, while 2" or thicker sod takes many days before the roots will extend themselves and grip the bank. If the sod has been cut too thick, heavy tamping after laying will tear loose the sod and roots and encourage more rapid growth of new roots.

Sodding is done both in hot summer weather and in the cold winter weather as the roots will grow even when the top grass does not. The bank should be dressed to a uniform grade and 1" below the top edge of the concrete lining to support the blanket of sod. The bank should not be cut below the top edge of the lining until the sod is to be laid, as the overhanging slope or bank is a protection against erosion at the concrete lining edge until the sod is laid. If the sod is being laid on a dry bank, the slope should be wet down thoroughly before laying.

As soon as the sod is placed and well tamped with shovels, it should be covered with $\frac{1}{2}$ " of earth which is accumulated from the bank as it is prepared to receive the sod. The sod blanket is extended to the top of the bank and over the top for several

inches. We have had very little success with spot sodding, and even when used only on the upper half of the banks, the repairing of the upper half for sodding after damaging rains has convinced us that we should do a complete job at first.

On deep ditches where a $1\frac{1}{2}$ to 1 slope would give a wide top, the bottom width may be increased and a rip-rap wall on a $\frac{1}{2}$ to 1 slope installed to a height of 3 or 4' and then a $1\frac{1}{2}$ to 1 sodded slope for the rest of the bank will result in a narrower top and still maintain the most desirable slope, $1\frac{1}{2}$ to 1 for dirt or sodded banks.

RIP-RAPPING

The term rip-rapping has been used in our ditching work to mean the use of broken pieces of concrete or stone with one smooth surface, as from a concrete sidewalk, floor, porch, wall or street. Old asphalt has been used but its tendency to crumble when not in use supporting traffic, has influenced us to use it for fill only. Some of our early work was with asphalt, and in years to come we will learn more about its possible use. This rip-rap may be used in big ditches for bottoms and walls or may be used on the sides of a small center concrete lining to increase the bottom width while having a concrete center lining to carry the dry weather flow. Again the rip-rap can be used in many cases to narrow a section of ditch to secure a uniform width, by building a wall and filling behind it. Shallow filling and sodding in place of a wall may be done if the existing bank is first spaded up or turned over to make a good bond between the existing and the new bank just as a roughening of an old concrete surface is necessary to secure good bond with a new layer of concrete. The wall need not be brought to the top of the bank if the bank is sloped and sodded above the wall, with the sod extending over the

top of the wall to the inside edge. In other places shade, due to bridges or trees, may make it necessary to use rip-rap in place of Bermuda. Walls may be used on sharp bends where scouring action is particularly severe.

As indicated above, some of the ditch lining installed by the C.W.A. about a year ago, was not sodded, and in cases considerable scouring and washing has taken place necessitating filling and widening the bottom and building side walls.

In constructing a complete rip-rap lining of walls and bottom, the walls are installed first. It is important in getting a uniform alignment to use slope stakes for the top and bottom and slope of the wall, usually $\frac{1}{2}$ horizontal to 1 vertical. The wall must be carefully constructed to stand and a solid foundation or footing is of first importance. The wall is begun a foot or more, if necessary, below the grade of the ditch to reach a firm foundation of dirt. The pieces of rip-rap are placed with the flat side up, not parallel to the bottom of the ditch, but perpendicular to the slope of the bank, the straightest edge is placed out as a part of the wall surface. At sections of ditch, where the velocity or scouring is severe the wall joints may be filled by slapping and brushing a 1:4 mix of cement mortar into them. Weep holes are left about every 25' to allow water entrapped behind the wall, especially in fills, to seep out into the ditch.

The bottom is built up or cut to a grade so that the flat face of the rip-rap when placed will meet the final grade line of the ditch lining. If the bottom can be lined when dry, care should be taken to have the dirt bottom firm and well tamped when fill is necessary. If the bottom is lined when the ditch is carrying a flow of water, rip-rap should be used to fill holes and a gravelly or coarse material should be used for fill with the voids filled with

dirt. As the rip-rap is laid on the bottom, each piece is placed carefully just as in building a wall, and tamped with the dirt bottom scraped away or added to make the flat piece of rip-rap lay flat and firm and to grade. A man on the bank slides pieces of rip-rap down to a man in the ditch who passes each piece to the rip-rap layer as he needs it. A half dozen or more crews may be placing rip-rap at the same time.

After all of the rip-rap has been placed, a finish man with a helper goes the entire length of the section, tamping and testing each piece to be sure all are firmly placed and to grade. On a wide bottom, a straight edge is used from the center line grade to the side of bottom grade to insure a uniform bottom with a slope to the center line for dry weather flow and no low or high places to cause water to stand.

Gravel and sand can then be brushed into the space between the pieces and tamped to "key up" the lining. A 1:4 mix of cement mortar is then brushed over and into the lining joints.

The sod should be placed on the dirt bank above and over the top of the wall and extend from the inner edge of the ditch walls to several inches over the top of the bank. It is important to tamp and settle the dirt-fill behind the wall to prevent later settling and slipping of the wall in places. If broken stone is used for fill, the voids should be filled with dirt and tamped as the fill is made and then covered with a blanket of sod.

In general, the cost of the concrete lining has run about 10 cents per square foot for material, including the cement, sand and gravel, while in the rip-rap work the only material purchased is cement and sand for grouting, as the broken concrete has been free for the hauling, and this has run about 1 cent per square foot. All sod used has been free. Because of the use of relief labor, no attempt has been made to

show unit costs of excavation or laying concrete, rip-rap, or sod. A total of 5.8 miles of ditches have been stabilized to date and a proposed project is now being submitted for lining and sodding 16.6 miles with an 18" to 24" concrete lining with sodded banks. Rip-rap will be used for walls, etc., where necessary.

SUMMARY

Lining of ditches with concrete and sodding, or with rip-rap material and sodding is being constructed in Mem-

phis with relief labor. A large force of common labor can be used with a small outlay of materials and equipment with a lasting and important influence on health. The maintenance cost is low, flood damage by erosion and loss of public and private property is stopped.

Certain lessons have been learned in constructing approximately 6 miles of ditch lining.

NOTE: The photographs included in this article were made by M. F. Carter, Memphis Health Department.

Pine Board Gavel

WHEN next year's meeting of the Western Branch of the American Public Health Association is called to order at Vancouver, B. C., Dr. W. F. Cogswell of Helena, new president of the organization, will rap sharply on the table with the official permanent gavel of the group—a common piece of Montana yellow pine board.

Rising to an emergency at this year's meeting in Helena in July, Dr. W. P. Shepard of San Francisco, secretary of the association, hurriedly found the piece of board and offered it to Dr. W.

H. Brown of Palo Alto, Calif., who was presiding.

The improvised gavel was used at most of the convention sessions and, after Dr. Brown had employed it for the final time during his presidency, Dr. Shepard had the out-going president autograph the board, which was turned over to Dr. Cogswell with instructions to have it available at next year's convention, as then and there it was proclaimed the official gavel of the organization for all future sessions. —*Montana Record Herald*, July 5, 1935.

Measles, Scarlet Fever and Whooping Cough in the Los Angeles County Health Department Area

A Ten Year Study

H. O. SWARTOUT, M.D., DR.P.H.

Assistant Professor of Public Health, College of Medical Evangelists; Emergency and Consultant Physician, Los Angeles County Health Department; Los Angeles, Calif.

THESE three "diseases of childhood" have been studied so long and written about so often that a full list of authors and titles would be bewilderingly lengthy. Nearly everything important that has been published about them has already found its way into the textbooks, with the exception of some recent developments in immunization and treatment. Since these two phases of the subject will be scarcely more than mentioned in this paper, references will be given only to a few standard works on general medicine, whose indexes and bibliographies are readily available to anybody who wishes to follow the study further.

There are several reasons why it seems worth while to present certain facts about the epidemic courses, prevalence, and severity of the three diseases as they have occurred in the Los Angeles County Health Department area.

First, the population is large enough to make the findings significant, having grown from a little less than half to a little more than three-quarters of a million from 1925 to 1934.

Second, the population is both mixed in type and markedly mobile, charac-

teristics which increase the frequency of personal contacts and which, therefore, might lead one to expect a communicable disease morbidity above the average.

Third, the area concerned is virtually sub-tropical, with no weather that can properly be called cold, and with distinct moist and dry seasons, thus differing appreciably from the areas covered by most studies on the same or similar subjects.

Fourth, the area has been under the administration of a well organized health department throughout the period, which insures comparatively dependable statistics.

Fifth, while some of the ascertained facts are in close agreement with general findings and opinions published in textbooks, others show interesting differences.

The statistical data are embodied in a series of charts, a discussion of which will make up the larger part of this paper.

Chart I shows the epidemic waves of the three diseases, based on annual case rates. Blackfan¹ mentions the regularity of measles epidemics as a generally recognized feature of the disease.

CHART IV.

Annual Death Rates

CHART VII.

Average Death Rates by Age-Groups

CHART VIII.

Case Fatality Rates by Age-Groups

Los Angeles County data are in agreement with this idea, for measles has been markedly epidemic there at intervals of just three years throughout the past decade. In non-epidemic years the incidence of measles has been very low. If the regularity of the wave persists, 1936 will see another measles epidemic in the county.

Scarlet fever and whooping cough epidemic waves have not shown much regularity, and the difference between the height of their crests and the depth of their troughs has not been marked. Scarlet fever peaks of moderate height occurred in 1926-1927, 1929 and 1933-1934. The whooping cough peaks came in 1925, 1929 and 1932-1933.

Chart I seems to say that little has been accomplished toward reducing the prevalence of measles, and that scarlet fever and whooping cough are becoming more prevalent. The chart, of course, is subject to the error of incomplete reporting. Those competent to judge hold that both measles and scarlet fever reporting in the area have been very good for at least ten years. Whooping cough reporting is not so good, but it is better now than it used to be ten years ago. The testimony of Chart I, therefore, is acceptable in a general way with regard to measles and scarlet fever, though it is possibly wrong in indicating an increasing prevalence for whooping cough.

Chart II shows seasonal variation in incidence by means of average monthly case rates.

While averages for corresponding months of the 10 years do not necessarily show that relatively high rates characterized the same months for most of the years, such, in fact, was true. In Los Angeles County it has been uncommon for the epidemic peaks of measles, scarlet fever, or whooping cough to occur at any other times in the year than those corresponding to the peaks in Chart II.

With respect to measles, Stevens ²

states that the maximum intensity of epidemics is usually in the winter months; Strong ³ says the seasonal incidence varies slightly in different latitudes, but is usually greatest from December to May; and Blackfan ¹ puts the greatest frequency of epidemics in winter and spring. In Los Angeles County, the greatest intensity of measles epidemics has been quite regularly between February and June, with the peak in April.

Chart III indicates that epidemic years did not dominate the measles picture with respect to seasonal incidence. The curve of measles cases for the 7 non-epidemic years rose and fell during the same months as did that for the 3 epidemic years.

It would seem that measles, generally called one of the most contagious of all diseases, should spread most rapidly when people, especially children, congregate most frequently. This thought points to the opening of school in September as the time when the measles curve should begin to rise. It does, in fact, do so; but the rise is gradual for 3 or 4 months, a longer lag than would probably occur if contagion alone were concerned. The remarkable seasonal regularity of the measles curve in Los Angeles County forces a consideration of the influence of the weather. Temperature is not the only weather factor, for the coming of cool days in November or early December does not cause a marked increase in the incidence of measles in the area. The decided upturn of the curve does, however, coincide quite closely with the early part of the rainy season, which, on the average, is well under way by the first of January. This noticeable coincidence with a season combining dampness and chilliness supports the idea of those who hold that conditions predisposing to upper respiratory infections are important factors in the rapid spread of measles.

Referring again to Chart II, it is interesting to note the combined influence of the school session and a cool and damp season on the curve of scarlet fever, the school session in this case being apparently the more significant of the two. Helmholtz⁴ also makes special mention of school term coincidence. This feature would seem to place great emphasis on contagion in connection with scarlet fever; yet it is generally considered much less contagious than either measles or whooping cough, whose curves of incidence in Los Angeles County do not follow the school term nearly so closely as does that of scarlet fever.

Stevens⁵ says that whooping cough is more severe, though not more common, in winter and spring. Levy⁶ says it is especially liable to occur during cold seasons. Holt⁷ places its prevalence mostly in winter and spring. In Los Angeles County, the seasonal curve of whooping cough is somewhat different from what these authorities would lead one to expect. Neither weather predisposing to upper respiratory infections nor attendance at school with its marked influence on contagion seems to affect the curve as promptly as would seem reasonable. The peak comes near the end of the school year, and when the weather is comparatively warm and dry.

Chart IV is an encouraging picture in some respects. It shows that while the annual death rate from scarlet fever in Los Angeles County is a little higher than it was a decade ago, measles is somewhat less of a menace to life than it was then, and whooping cough much less so. Whooping cough, however, is not much less of a life peril now than it was 4 years ago; and it still takes a larger toll year by year, on the average, than either measles or scarlet fever.

Chart V is a good measure of the relative severity of the three diseases. In it, again, scarlet fever gives no

grounds for satisfaction; but the measles curve shows that this disease has been growing definitely less deadly. As to whooping cough, while nearly 5 per cent of those reported to have the disease in 1925 died of it, and more than 5 per cent in 1926, during each of the past 3 years less than 1 per cent of the reported cases ended fatally. What has caused so marked an improvement is not clear. There has doubtless been some gain in the quality of medical and nursing care, though the depression has surely cut down on the quantity and there has been some increase in the use of pertussis vaccine, though not much; but neither of these factors nor a combination of them is at all commensurate with the decrease in whooping cough case fatality in Los Angeles County.

According to a composite view of statements from the authors already named, measles mortality, under favorable surroundings and averaged for all ages, runs from 3 to 6 per cent. In Los Angeles County, in only 1 year in the past decade did it go above 1 per cent, in 6 other years it was less than $\frac{1}{2}$ per cent, and in 1929 it was zero.

A similar study of scarlet fever leads one to expect a mortality of from 1 to 8 per cent, but in Los Angeles County it has never reached as high as 1 per cent during the past 10 years.

Stevens⁵ gives whooping cough a reputed mortality of from 3 to 10 per cent. In Los Angeles County, only 3 years in the last 10 saw a whooping cough mortality above 3 per cent; and for the past 3 years it has been below 1 per cent.

In general, the severity of the three childhood diseases — measles, scarlet fever, and whooping cough — as they occur in the Los Angeles County Health Department area, is evidently below the average for the other localities that have been studied. In the case of measles and whooping cough, this severity is definitely declining. The

data, however, do not indicate that the virulence of the streptococci causative of scarlet fever is decreasing in that area, a condition which has been suggested as possibly obtaining in our country as a whole.

Chart VI shows how age affected the incidence of the three diseases. Both measles and scarlet fever showed a fairly steady increase during the first 5 years of life. Multiplying opportunities for contagion as the children widened the circle of their activities and added to the number of their playmates may have been enough to account for this increase. With whooping cough, the incidence ran nearly the same for each of the first 5 years, though the factor of increased likelihood of exposure was as great as in the case of the other two diseases. The total number of cases reported for the first 5 year age group was almost exactly the same as for measles, indicating that the number of susceptibles in the population did not differ much for these two diseases. A study of all these findings leads one to wonder if there is not something in the idea that some not fully demonstrated physical condition or change makes children individually less susceptible to whooping cough as they grow older.

Decreased susceptibility to whooping cough continued to manifest itself during the second 5 years of life, when by entrance to school the chance of contagion greatly increased. In this respect, measles and scarlet fever told a very different story, for school entrance brought a sharp rise in their incidence.

The markedly decreased incidence of all three diseases during the third 5 years of life might plausibly be accounted for by the guess that such a large proportion of the population had already had them that few susceptibles were left. Comparing the average annual number of reported cases in children under 10 years of age with the average annual number of new suscep-

tibles born into the population with an expectancy of living to the age of 10 years gives an approximate estimate of the comparative numbers of susceptibles and nonsusceptibles in the population 10 years old or over, among whom records show that the number of cases is almost negligible. Such an estimate leads to the conclusion that at least two-thirds of the population of Los Angeles County over 10 should still be susceptible to measles, at least five-sixths to whooping cough, and at least seven-eighths to scarlet fever. It is incredible that such large proportions of susceptibles should really exist, at least in the case of measles, in view of the known instances where this disease has attacked nearly every member, old or young, of a community which it has invaded after being absent from it a generation or two.

A large number of unreported cases would help to explain this anomaly; but the Chief of the Bureau of Communicable Diseases of the Los Angeles County Health Department believes that reporting has been 90 per cent or better for measles, 95 per cent or better for scarlet fever, and is now 75 per cent or better for whooping cough, though it may have been as low as 50 per cent 10 years ago. At least three pertinent questions, therefore, are left unanswered: Have there been many "missed cases"—no diagnosis having been made? Has a considerable degree of immunity in people supposedly susceptible been developed as a result of exposures that did not lead to detectable symptoms? Do people in lands where the diseases are more or less endemic naturally become more nearly immune to measles, scarlet fever, and especially whooping cough, as they grow older?

Chart VII gives an idea of the varying life toll taken by the three diseases as they affected people of different ages. Measles has taken its largest

number of lives during the 2nd year of life, scarlet fever during the 4th, and whooping cough outstandingly so during the 1st. For children under 5, whooping cough has been by far the greatest killer of the three.

Chart VIII combines the factors of incidence and comparative danger to life, giving an idea of the chance children of different ages had of living or dying if attacked. Here, again, measles showed a peak during the 2nd year. It not only took a larger number of lives at that age, but killed a larger percentage of the children who had it. Scarlet fever, though more common in all later years up to 10, was more fatal in the 1st year. Whooping cough was extremely fatal during the first year of life. It ran about even with measles during the next 4 years. None of the three diseases was very serious in children over 10, but scarlet fever was considerably more so than either of the other two.

Textbook statements are in general agreement with what is shown by Charts VII and VIII.

CONCLUSION

It may be said that the records of measles, scarlet fever, and whooping cough during the past decade in the Los Angeles County Health Department area indicate that:

1. Climate and season have had considerable influence upon the incidence of the dis-

cases, and have tended to make the peaks of the epidemic waves come unusually late, especially for measles and whooping cough.

2. Exposure by personal contact may have played a greater rôle in the incidence of scarlet fever than textbook discussions would lead one to expect, and a lesser rôle in the incidence of whooping cough.

3. Case fatality rates for all three diseases have been very low. They are apparently not so great a menace to life in a subtropical area as they are in colder regions.

4. The streptococci causative of scarlet fever do not appear to be growing less virulent in the Los Angeles County Health Department area.

5. Natural susceptibility, decreasing with age, may have been an important factor in incidence, especially in the case of whooping cough.

6. Judging from the numbers of reported cases, an almost incredibly large proportion of the population over 10 years of age should still have been susceptible to measles, scarlet fever, or whooping cough. Why more people above 10 did not contract these diseases has not yet been clearly explained.

7. Below the age of 5, whooping cough was by far the greatest killer of the three; and above the age of 10, scarlet fever.

Experts Wrong and Genuine

THERE is always a certain attraction about the wrong kind of expert, about going to the man who knows nothing about it, because you are

afraid if you get a genuine expert his opinion would go against you, as indeed it very often would.—*Bernard Shaw.*

The Teaching of Epidemiology by Applicatory Problems

EDWARD L. MUNSON, M.D.

*Professor of Preventive Medicine, Medical School, University of California,
San Francisco, Calif.*

Brigadier General, Medical Department, United States Army, Retired

INSTRUCTION in the subject of applied epidemiology is obviously handicapped by certain inherent difficulties of presentation. While other branches of the medical curriculum may have their didactic teaching concretely demonstrated by laboratory procedure or illustrated in appropriate relation by clinical cases, the same is not true in respect to epidemiology. Epidemic outbreaks of communicable disease cannot be created for purposes of pedagogy; and where these have naturally occurred the conditions are habitually such that the resulting problems can scarcely be brought into the classroom for current solution.

Accordingly, much of the instruction in epidemiology is necessarily didactic and of a general nature; and the tendency is, in the formulation of test questions, to determine what amount of the information so given has been retained. This, so far as it goes, is of course desirable.

But for practical purposes it is quite as important to determine the ways and degrees in which the information so given is applied by the student—for after all the only real value of education lies in the practical use which is made of it. The whole purpose of instruction is to bring about prepared reactions to certain conditions liable to occur in the future. So far as epi-

demiology is concerned, such prepared reactions will rest on the known biological facts pertaining to the organisms concerned, and as affected by environmental conditions.

After the foundation of facts and methods has been didactically laid, any further development of epidemiology depends upon their practical application in the study and solution of problems. These problems may be hypothetical, or they may be cross-sections of some actual epidemiological occurrence. The former are demonstrably more adapted to teaching purposes. Past epidemics may be studied as abstract situations, but they lack the vivifying interest that attaches to the solution of a present emergency. Further, their actual conditions may not lend themselves to certain epidemiological features which it is desired to demonstrate. Finally, in such study, the tendency is merely to call attention to the channels of procedure which were actually employed, and particularly to those which led to a positive solution. Taught in this way, applied epidemiology requires nothing of the student in respect to the formulation by him of working hypotheses adapted to the specific conditions, and the pursuit of such hypotheses to their logical conclusion.

On the other hand, an artificially pre-

pared problem has no limitations which might interfere with the presentation of any phases which it may be desired to illustrate—just so that the situations assumed are logical and in accordance with accepted scientific facts. Such problems may be wholly synthetic, or they may be drawn up on the basis of an actual occurrence. However, there is no real teaching advantage in the latter, for a properly prepared hypothetical problem may be made equally realistic.

Problems may be classified as those which are static, usually representing a single situation intermediate in what has gone before and what is yet to come; and continuing problems, which comprise a series of coördinated situations, leading progressively to an ultimate conclusion.

A static problem must contain within itself appropriate factors and data to give a sufficient epidemiological picture, and is to be solved on the basis of an unchanging situation. It implies the selection of the single hypothesis best conforming to the announced data, and the formulation of a solution based thereon. Under such conditions, the factor of uncertainty as to procedure due to possible change in the situation is eliminated; and with the long time-factor usually allowed the student for solution, rapidity of thinking as well as selective use of the reasoning powers is ordinarily not a requirement. Such a restricted problem corresponds to the "map problem" which forms a part of the early training of army officers in the principles of tactics. In both instances such limited problems serve a very valuable purpose for elementary presentation—but they do not go far enough for the more advanced instruction.

The continuing problem is drawn so as to develop gradually through a series of progressive, correlated and logical phases. In it, the element of uncer-

tainty is present up to the final decision and action; the qualities of reason, evaluation, and deduction must be constantly in operation; and suitable procedures must be progressively outlined in the absence of any positive knowledge as to the changing situations which may develop. Such a continuing problem is like an army "war game," in which appropriate action must be taken with each shift of the controlling conditions.

By reason of his military training, the writer is necessarily conversant with the methods of preparation, conduction, and solution of army war games, and has adapted their principles to epidemiological problems. The results have been so practical and satisfactory, as shown by experience in this medical school, as to warrant their description to those who might be interested. Further, there seems reason to believe that the method may be useful in other branches of medical science having a changing picture, as in diagnosis, therapeutics, and prognosis.

In the Medical School of the University of California, the solution of such continuing epidemiological problems comes in the senior year, toward the end of the general course in preventive medicine, requiring the student to make specific application of the general principles already laid down. These problems greatly interest the class, and are probably the most popular exercises of the whole 3 year course. The gradual development of their solution has all the fascination of following through a mystery or detective story—and, in fact, the same general principles of logical sequence, relationship, evaluation, and inference are applicable in both instances. For the demonstration of such principles, one might even go so far as to recommend such stories as "The Adventures of Sherlock Holmes" as collateral reading in relation to applied epidemiology.

The preparation of an illustrative epidemiological problem is something of an art. The instructor, while restricted to scientific facts, must use a logical imagination in their selection and relation, and should endeavor to vivify and dramatize their presentation. The formulation of the problem depends, as to its character and phases, upon the requirements which it is desired to develop; and the nature and sequence of its successive situations are assumed and presented with that purpose in mind.

As with the writing of mystery stories, it is probably easier to decide first upon the climax and denouement, and write them out in the form of the solution contemplated. With this predetermined ending in mind, the instructor now works back and prepares as many antecedent and correlated situations as may be desired. Each such situation is so drawn as to bring out the points which it is desired to illustrate; and is followed either immediately or later by the correlated facts and the inference or conclusion based thereon. Finally, a preamble in the form of a "general situation" is drawn up as the basis of the problem, in such broad general terms as to permit of the various developments and changes which have been prepared to follow. The sample problem given herewith illustrates the possible diversity of presentation along the lines of development chosen; but it would have been equally possible to have changed its several sequent phases so as to make them demonstrate quite different situations, lines of procedure, and end-result.

For the development of such a continuing problem in the class-room a special procedure is essential.

1. It is presented to the class for solution as a series of coördinated situations, each of which is followed by an outline of its appropriate solution. This is done by the use of consecutive

lantern slides, each of which pertains exclusively to a special phase or situation.

2. The class, both individually and collectively, solves each of these situations as it is thrown on the screen. This is done by designating a student as principal to make the initial statement as to what should be done under the prescribed circumstances and another student as alternate to amplify or comment upon such initial statement. The class as a whole is then called upon for comment and criticism upon both statements.

At the expiration of the time-limit for the phase in question, its approved solution is then shown on the screen, and is open to general inquiry or comment by the class as a whole.

3. A time-factor governs the solution of the problem. For such a problem as is shown herewith, approximately 4 minutes is allowed for each separate phase. This 4 minute period is subdivided about as follows: 1 minute for general consideration, 1 minute for the answer by the principal, 1 minute for comment by the alternate, and 1 minute for discussion by the class. In practice, the general discussion usually figures out at more than 1 minute, as the principal and alternate do not ordinarily consume their full allotted time.

The imposition of a restricted time-factor has a very definite teaching value; not only moving the problem along steadily, but requiring the student to think rapidly as well as accurately. Experience shows that very satisfactory results are attained within the relatively brief period allowed for consideration.

4. Besides his answer, the student is expected to outline briefly the reasoning by which he reached his conclusion. This implies the enumeration as well as application of any facts considered as pertinent, and is a valuable training in

logical deduction. It also suggests points for consideration and discussion by the class.

The limitations of both lantern slide space and time-factor require succinct presentation of the basic ideas appropriate. The student must be brief and to the point, and generalizations and alternative procedures are not acceptable.

5. The instructor takes no part in the problem, other than to see that the time-factor is maintained, to raise inquiries as to deductions, and to answer briefly questions as to the approved solutions.

6. The method secures the mainte-

California city of about 25,000 population, and must do your epidemiological work yourself.

Disposal of excreta is by sewers; except in the suburbs, where a moderate number of privy vaults are in use. The water supply comes from a stream that is unsafe; but has an efficient chlorinating apparatus, which is checked by the laboratory every Tuesday and Friday. About two-thirds of the milk sold in the city is pasteurized. No typhoid case has been reported during the past 6 months.

First situation—December 1—
The following card has just been received by you:

REPORT OF A CASE OF COMMUNICABLE DISEASE

MAIL THIS CARD IMMEDIATELY. NO POSTAGE REQUIRED.

USE THIS SIDE TO REPORT ONE CASE ONLY.

Place and date -- City, Dec. 1, 193-

Disease Typhoid fever Onset About Nov. 27.

Name of patient John Smith Age 27

Address of patient 121 First Ave. Race White

School attended Employed at 211 Green St.

Probable source of infection unknown

Vaccination history:

If smallpox, when successfully vaccinated

If diphtheria, how many doses Toxin antitoxin Date

If typhoid, how many doses None When Where

Remarks: Agglutination positive. Large family in poor circumstances.

I first saw this patient at 4 P. M. o'clock on Nov. 29.

Signature of physician A. G. Goodman

Address of physician 44 Main St.

nance of the most intense attention and interest by every member of the class, for each is liable to be called upon for his own opinion at any stage of the problem.

The following problem, which is based on an actual epidemiological occurrence, is offered as an example of practical possibilities of such exercises.

EPIDEMIOLOGICAL PROBLEM—TYPHOID FEVER

General premises—
You are the Health Officer of a

What immediate steps by you are indicated?

- Answer to First Situation—
1. The case being a positive focus, it should be handled first.
 2. Remove and confine the infection by hospitalizing and quarantining John Smith.
 3. Destroy any potential intermediate foci by terminal disinfection of all objects liable to have been contaminated by the patient.

Second Situation—December 1—
John Smith has a wife and 4 children. None of them gives a history of previous typhoid.
What are you going to do about them?

Answer to Second Situation—

Start their immunization at once by a course of antityphoid inoculation.

Third Situation—December 1—

"Doctor," Mrs. Smith asks you, "how do you suppose John might have caught his typhoid?"

Answer to Third Situation—

"Well, Mrs. Smith," you reply, "nobody catches typhoid fever—he swallows it!"

"John could have been infected by direct contact with a case or carrier; or indirectly through contaminated water or food. Flies may carry the infection—but at this time of the year the flies could not be a factor in John's case."

Fourth Situation—December 1—

Diligent inquiry fails to reveal any probable local source of John's infection.

It develops, however, that on November 13 and 14 he was hunting at a ranch some 20 miles out of town, where the drinking water came from a shallow well.

What may you infer?

Answer to Fourth Situation—

You can make no definite inference.

Because of the wide limits of the incubation period of typhoid, it was possible for John to have acquired his infection either in his home town or at the ranch.

Fifth Situation—December 2—

James Jones has just been reported as a typhoid case, with onset about November 28.

It develops that he is a great friend of John Smith. They work at the same place; lunch together at Restaurant A; and were on the same hunting trip at the ranch.

What are now your inferences and actions?

Answer to Fifth Situation—

1. *Inferences* as to possible alternative sources of both infections remain unchanged.

2. *Actions—*

a. Telephone County Health Officer to ascertain antecedents of ranch as to typhoid fever.

b. Investigate conditions at place of work of Smith and Jones.

c. Investigate conditions at Restaurant A.

d. Determine source of milk supply of Restaurant A.

e. Check laboratory reports on local water supply.

vious typhoid at the ranch. Conditions at the Smith-Jones place of business seem satisfactory. Restaurant A reports a new cook hired on November 1, who admits typhoid a year ago. Its milk supply comes from Dairy B, and is not pasteurized. Laboratory reports of water analyses since September 1 show no positive *B. coli*.

What may now be potential sources and what will you do about them?

Answer to Sixth Situation—

1. The new cook in Restaurant A may be a possible carrier. He will be cultured, and ordered to stop work until laboratory results have been received.

2. The milk supply may be at fault. Conditions at Dairy B will be investigated.

3. The ranch well still remains a possibility.

4. No evidence incriminates the city water supply.

5. Flies can be definitely excluded from the problem.

Seventh Situation—December 2—

Your representative who inspected Dairy B reports conditions as apparently satisfactory.

Reports have just come in of 2 new cases (Brown and Robinson) as having developed about November 29. Both used Dairy B milk. No other connection between them, or with the Smith and Jones cases, can be traced.

On the basis of information so far received, you roughly sketch out relationships as shown in Figure I.

FIGURE I

*Sixth Situation—December 2—*

The County Health Officer reports no pre-

What are your inferences and actions?

Answer to Seventh Situation—

1. The practically simultaneous occurrence in 4 users of milk from Dairy B is suggestive.

2. Prohibit sale of this milk until further notice, unless pasteurized.

3. Order the dairy operatives cultured, and warn them as to all necessary precautions.

4. Telephone all physicians that 4 typhoids have occurred, and to be on the look-out for others.

Eighth Situation—December 3—

Six new cases, widely scattered, are reported today, with onset as of about November 30. Only 2 of them have used milk from Dairy B. None of them—nor the Brown and Robinson cases—were out of town during November.

What may you now infer?

Answer to Eighth Situation—

1. Since only the Smith and Jones cases have been out of town during the incubation period, the last 8 cases must have a local source.

2. Dairy B milk remains under suspicion, for 6 of the 10 cases have used it.

3. Laboratory reports on cultures from the restaurant cook and dairy employees are awaited.

Ninth Situation—December 4—

Twelve new cases are reported today, as having developed about December 1. Only 1 of them used Dairy B milk. The laboratory reports that cultures from the cook at Restaurant A, and from the employees of Dairy B, are so far negative.

What are now your inferences?

Answer to Ninth Situation—

1. That the infection in over 90 per cent of cases must have been acquired locally.

2. That some other source than milk from Dairy B must be looked for.

3. That the possibility of a carrier in Restaurant A can presumably be eliminated.

Tenth Situation—December 5

Eighteen cases are today reported as having developed about December 2. Your chart of the course of the outbreak is shown in Figure II.

How will you interpret it?

Answer to Tenth Situation—

1. That the infection invaded about the middle of November.

2. That the invasion was abrupt, and probably from a single source.

3. That its concentration was probably considerable.

4. That there was some common vehicle of distribution.

5. That this vehicle had a more general and wider distribution than unpasteurized milk.

6. That the only other vehicle satisfying the requirements is the city water supply.

7. That the antecedents of this water should be rechecked.

Eleventh Situation—December 5—

You question the man at the water purification plant. "Tell me exactly," you demand, "what happened to your chlorinization apparatus about a fortnight ago!"

Under pressure, he admits: "Well, you see, Doctor, late on a Saturday afternoon—I think it was November 18—I found that the cylinders had run out of gas, and I couldn't get a new supply until Monday morning."

What are now your conclusions?

Answer to Eleventh Situation—

1. That raw water, known to be habitually unsafe, was distributed to the community for nearly 2 days.

2. That laboratory tests were too infrequent to discover it.

3. That so far as the epidemic is concerned, all other hypothetical sources can safely be disregarded.

Twelfth Situation—December 5—

What statement of public assurance are you now in position to make to the community?

Answer to Twelfth Situation—

Your knowledge that the infection began on November 18, and continued for a couple of days, introduces a definite time-factor into your problem.

You are accordingly in position to say:

1. That the source of the typhoid outbreak has been determined.

FIGURE II

2. That it was an infected water supply, resulting from temporary lack of chlorinization.

3. That this water was shortly—and is now—again safe for use.

4. That the epidemic has now probably about reached its peak.

5. However, that cases in waning numbers, from the infection now incubating, may be expected to develop for about another week.

SOME EPIDEMIOLOGICAL AXIOMS

1. Hasty assumptions may give rise to erroneous conclusions.

2. The interpretation and evaluation of evidence may be more important than its temporary volume.

3. The *course* of an epidemic often suggests its probable *source*.

COMMENT

The foregoing problem was formulated with the purpose of bringing certain definite factors, which had been decided upon in advance, into logical interplay in relation to public health. Among these are the general sanitary conditions which might be expected in a small city; the use of the official notification card in reporting a case of typhoid fever; initial health requirements based on such report; immunization of close contacts; ways by which typhoid infection may be acquired; the incubation period, the time element, and the factor of season; various potential sources of infection, as case,

carrier, well or city water, restaurant, milk, flies; inquiries and inspections to be instituted, including laboratory investigations; the formulation of working hypotheses; effect of accruing evidence, both positive and negative, on the relative values of these hypotheses; appearance of further cases, and trend toward epidemic; inquiry with graph as to possible relationship between cases and potential sources; warning of the profession as to liability to outbreak; rapid development of epidemic conditions, with distribution of cases; discarding of hypotheses as they become untenable, and the strengthening of others; the sudden development of an epidemic; interpretation of its graph in respect to probable source; aid of statistical charts in epidemiological diagnosis; basic importance of verifying contributing data; the element of human frailty as possibly a determining factor in health problems; the need and nature of reassurance of the community; epidemiological axioms illustrated by the developmental procedure.

Analysis of the various situations of the foregoing problem shows that all these major factors in epidemiology, with others, are brought out and briefly demonstrated by them in appropriate sequence and ultimate logical perspective.

Eosin Methylene Blue Agar for Rapid Direct Count of *E. coli*

H. W. GEHM AND H. HEUKELEKIAN

*Department of Water and Sewage Research, New Jersey Agricultural
Experiment Station, New Brunswick, N. J.*

SCHULHOFF¹ working with *E. typhi* in sewage, perfected a method of obtaining excellent colony distribution of surface growth on brilliant green agar. We have applied this method to counting *E. coli* using eosin methylene blue agar as a medium.

Eosin methylene blue agar with and without crystal violet (1-100,000) were compared and it was found (Table I) that although the presence of crystal violet cut down the contaminants it also cut the colon numbers to an extent that would prohibit its use as a direct counting medium.

TABLE I

EFFECT OF CRYSTAL VIOLET ON THE RECOVERY
OF *E. COLI* FROM EOSIN METHYLENE
BLUE SMEAR PLATES

<i>E. coli</i> per c.c.		
<i>Media</i>	<i>Sewage</i>	<i>Pure Culture</i>
Eosin Methylene Blue	110,000	3,780,000
Eosin Methylene Blue + Crystal Violet (1:100,- 000)	51,000	1,810,000
Brilliant Green Bile Broth	95,000	3,500,000

METHOD

Eosin methylene blue agar is prepared according to the standard method except that the use of 2 per cent rather than the usual 1.5 per cent of agar gives a firmer surface for smearing. Plates are poured to a depth of about 3 mm. Too thin a layer leads to the drying out of media if left in the

incubator too long during drying process and spreading of the inoculum under the medium.

One c.c. of the inoculum is run on the surface of the medium and smeared with the pipette so that the entire surface is covered. The plate is then tilted back and forth several times, thus running inoculum over the surface and obtaining a more even distribution.

The plate is placed in a 37° C. incubator and the cover removed. Drying of the inoculum occurs in about 1 hour. To obtain perfect distribution it is necessary to tilt the plate, as done at start, when the plate is about half dry.

When the surface is thoroughly dry, the plate is closed, inverted, incubated 24 hours, and characteristic colonies are counted.²

Contamination from leaving the agar surface exposed in the incubator was practically nil in incubators which were not particularly clean. Only 2, small non-colon colonies were observed on the 50 control plates run. The dyes present in the medium evidently inhibit bacteria which may be deposited on the agar surface with the dust from the air.

Excellent distribution of colonies was obtained by this method. However, in most cases it was not advisable to count plates containing many more than 100 colonies, for when too heavy inoculum is used a growth is likely to occur be-

TABLE II

COMPARISON OF RECOVERY OF A PURE CULTURE OF *E. COLI* FROM PLAIN AGAR, BRILLIANT GREEN BILE BROTH AND EOSIN METHYLENE BLUE SMEAR AGAR

Test No.	E. coli Thousands per c.c.		
	Plain Agar Av. 3 Plates	Brilliant Green Bile Broth Av. 5 Tubes	Eosin Methylene Blue Agar Av. 3 Plates
1	4,600	3,500	3,700
2	174	150	163
3	306	250	288
4	121	100	109
Mean	1,300	1,000	1,063
Per Cent of Agar Count		77	82

tween the edge of the plate and the medium, causing a mass of gas bubbles and colonies difficult of differentiation. Plates containing between 30 and 100 *E. coli* colonies give the most consistent counts. An additional 24 hours' incubation gave no higher count and usually over-growth spoiled the plate.

DATA AND RESULTS

As we were interested in applying this method to sewage in various stages of treatment, and heavily polluted waters, comparative counts were made against the brilliant green bile broth count which has been found to be a very satisfactory counting method for *E. coli* due to the high percentage of confirmation obtainable. Its disadvantages are that 48 hours' incubation time is required and that the final results are only rough approximation of the number present. The variation may be wide on account of the significance given to one tube by the probability tables.

The first work done was with a pure *E. coli* suspension. Counts were made in brilliant green bile, plain agar, and on eosin methylene blue agar. Judging from Table II, eosin methylene blue agar is no more inhibitive than brilliant green and should provide a satisfactory counting medium for *E. coli*.

Table III gives the comparative counts on sewages by the eosin methylene blue smear plate method and brilliant green bile broth tube method on 19 different sewages from 8 plants. The results show a close agreement of the counts by the two methods. In

TABLE III

COMPARISON OF THE RECOVERY OF *E. COLI* FROM SEWAGES BY EOSIN METHYLENE BLUE SMEAR AGAR AND BRILLIANT GREEN BILE BROTH

Sewage Sample	Eosin Methylene Blue Agar Av. of 3 Plates	Brilliant Green Bile Broth Av. of 3 Tubes
	Thousands per c.c.	Thousands per c.c.
1	38	25
2	75	45
3	79	25
4	91	75
5	100	68
6	106	95
7	110	95
8	124	150
9	130	100
10	134	95
11	161	250
12	162	250
13	163	150
14	166	150
15	200	250
16	220	250
17	260	250
18	285	250
19	458	450
Average	168	165

13 cases out of 19 the counts by the eosin methylene blue agar method were higher than brilliant green broth bile.

TABLE IV

COMPARISON OF THE RECOVERY OF *E. COLI* FROM POLLUTED WATERS BY EOSIN METHYLENE BLUE AGAR AND BRILLIANT GREEN BILE BROTH

Sample	E. coli per c.c.	
	<i>Eosin Methylene Blue Agar</i>	<i>Brilliant Green Bile Broth</i>
	Av. of 3 Plates	Av. of 3 Tubes
1	330	150
2	1,800	900
3	2,300	2,500
4	3,300	4,500
5	5,300	2,500
6	7,700	4,500
7	530	450
Average	3,037	2,214

Table IV gives a comparison of the counts obtained by the 2 methods from polluted waters. Here the average by the eosin methylene blue agar is appreciably higher than by brilliant green

broth tube, and in 5 cases out of 7 the counts were higher by the former method than by the latter.

The method was compared with brilliant green bile broth in determining the *E. coli* removal of various treatment units in a sewage plant. The results in Table V show a close agreement by the two methods. In most cases the eosin methylene blue count was higher.

Table VI gives the results of a similar study from the different parts of an aeration tank of an activated sludge plant and of returned sludge. The agreements by the eosin methylene blue agar and brilliant green broth bile are again close.

CONCLUSION

The results so far obtained indicate that the eosin methylene blue smear plate method is satisfactory for direct rapid *E. coli* enumeration. The outstanding advantages are as follows:

1. Confirmed results in 24 hours
2. Less work involved

TABLE V

COMPARISON OF REMOVALS OF *E. COLI* BY THE DIFFERENT UNITS OF SEWAGE TREATMENT PLANT BY EOSIN METHYLENE BLUE AGAR AND BRILLIANT GREEN BILE BROTH

Media	E. coli per c.c.					
	Raw	After Settling	After Trickling Filter	After Secondary	After Chlori-	Stream Below
				Sedimentation	nation	
Eosin Methylene Blue Agar	207,000	137,000	3,800	10,000	330	12
Brilliant Green Bile Broth	172,000	147,000	2,500	7,000	250	9

TABLE VI

E. COLI BY THE EOSIN METHYLENE BLUE AGAR AND BRILLIANT GREEN BILE BROTH IN ACTIVATED SLUDGE

	Sample	E. coli per c.c.	
		<i>Eosin Methylene Blue Agar</i>	<i>Brilliant Green Broth Bile</i>
Aeration Tank Samples:	Inlet	26,000	25,000
	Center	7,000	6,000
	Outlet	3,300	3,500
Return Sludge:	Hillsdale	10,600	11,000
	Tenaflly	185,000	250,000
	Tenaflly	173,000	150,000

3. Less equipment required
4. Media cheaper and easier to prepare
5. Comparable counts are obtained with brilliant green broth bile.

This method has been found to be particularly adaptable to sewage plant control and sewage research. Application of this method to river waters not heavily polluted appears possible. In this work a comparison should be made with lactose broth with eosin methylene

blue confirmation to see if the inaccurate, cumbersome enrichment count may be omitted entirely.

N.T.A. Meeting in Saranac Lake, N. Y.

THE thirty-first annual meeting of the National Tuberculosis Association was held in Saranac Lake, N. Y., June 24-27, celebrating the fiftieth anniversary of the opening of the "Little Red" cottage, which is still preserved on the grounds of Trudeau Sanatorium. The modern treatment of tuberculosis in the United States was begun here by Dr. Edward Livingston Trudeau in 1885. The occasion provided a setting for a dedication of the cottage on the afternoon of June 25 with hundreds of delegates gathered on the lawn to witness the presentation of a bronze plaque by Dr. Kennon Dunham, President of the Association, to Dr. James Alexander Miller, President of the Board of Trustees of Trudeau Sanatorium. The ceremony was made more interesting by greetings from Mrs. Carolyn P. Lindsay, of Albany, N. Y., the oldest living patient to have occupied the cottage. She was under treatment there in 1887.

On the same afternoon the Canadian delegation laid a wreath at the foot of Trudeau's statue on the grounds of the institution. This well known statue, by Gutzon Borglum, pictures Trudeau sitting in his cure chair and gazing off at his beloved mountains.

The meeting opened Monday evening, June 24, in the large auditorium

of the High School. The formal program was followed by tableaux dealing with the life of Trudeau presented by pupils of the High School.

The registration totalled 1,365, which was a record breaker for size.

The sessions were well attended, beginning with preliminary meetings of the American Sanatorium Association and the National Conference of Tuberculosis Secretaries on June 24 and ending with a joint symposium of the pathological, clinical, sociological, and administrative sections of the N.T.A., occupying the entire day of June 27. The general title of the symposium was "Present Concepts of Tuberculosis Infection and Disease; their Principles and Application." The morning session dealt with the clinical and pathological considerations. The afternoon session discussed the question of how the present knowledge of tuberculosis may be applied in community programs in the next decade.

Dr. James J. Waring, of Denver, was elected President for 1935-1936. The 1936 meeting will be held in New Orleans, April 22-25.

A full report of the proceedings of the Saranac Lake meeting will be published later in the year in the *Transactions of the National Tuberculosis Association*.

Diseases of the Peasants of Haiti

CAMILLE LHÉRISSE, M.D.

Former President of the Medical Society of Haiti and Professor of Biology in the National Medical School of Port-au-Prince

AMONG the 2,000,000 country people included in our population, diseases may be found to vary remarkably from one part of the country to another. In addition to clothing, dwelling, and diet conditions, the environment and geographical location, plain or mountain land, constitute a factor exerting considerable influence on the sanitary status of the rural people. As local officials often fail to send reports of deaths to the vital statistics representatives, and in some areas it is not possible to require the presentation of death certificates before burial, the result is that no reliable death statistics are available for the Republic as a whole.

These conclusions are based on the investigations of the Payne Mission of the Rockefeller Foundation (1924-1925), in which the writer participated, in the examination of several thousand emigrants going from Port de Paix to Cuba (1924-1929), in a large number (700) of necropsies we performed in the General Hospital at Port-au-Prince from 1927 to 1929, in our experience in rural dispensaries, especially at Kenscoff (August-September, 1928), at Taifer (January, 1929), and at those opened at Morne La Selle, Marché Lamarque (Nouvelle Tourraine Section, Pétion-Ville District) and at Berly (Port-au-Prince District) (May-September, 1929). Such studies allow us to visualize some of the sanitary problems confronting the Republic of Haiti.

The diet of the Haitian peasants has

not improved since the slavery period. As a rule, quantity is preferred by them to quality. While it may be claimed this satisfies their stomach sometimes, one cannot say as much for their bodies. It will not be possible to remedy these defective hygienic conditions until the ignorance of the masses is fully conquered.

While farm work is not the cause of the prevailing industrial diseases, the long hours and the ensuing fatigue, especially in some regions, in women and children, not uncommonly bring about rather serious injuries. Weeding under the summer sun, the preparation of coffee for the market, and the threshing of corn, are hard tasks which almost invariably are accompanied by an acute morbid condition. This condition is characterized by febrile attacks, headache, articular pains, and often an inflammation localized in lumbar muscles, resembling quite closely the clinical picture of sciatica.

Our peasants are also quite liable to traumatic injuries including serious falls. Ploughing machines frequently cause wounds which, on becoming infected, develop into enormous ulcers complicated by tetanus. Children and women often have to carry over poor roads, especially in the mountain regions, huge loads of lumber, water, fruits, building materials, etc. This overwork must end inevitably by damaging their health. The flattening of cranial bones, the exaggerated bending of the spine, the injuries or prolapse

of internal organs, muscular tremors, headaches, cannot fail to produce most harmful effects on the skeletal frame (for instance, on the female pelvis), and must affect the individual's working capacity.

This carrying of heavy weights for long stretches by ill-nourished persons, enjoying only short rest periods, exerts an undue pressure on the posterior portion of the chest. This makes inspiratory dilatation more difficult, increases the tendency to pulmonary and heart infections, decreases blood oxygenation, and paves the way to a resistant chronic anemia.

In women miscarriage becomes rather common as a result of such overwork. Mothers do not remain long enough in bed after parturition, which many times occurs by the roadside. Very often one sees them up and about the day after labor. The puerperium, often very difficult and staged under most disastrous conditions, is in charge of midwives in the neighborhood. These facts explain the defective development of the new-born, their lessened resistance to disease, and the high infant mortality in country districts, which, according to Payne, is 67 per 1,000 in children from 1 to 4 years, and 167 per 1,000 among infants. The same conditions explain the prevalence of abdominal diseases in women.

In a general way, farming and long walks often compel women to stop nursing their babies. A most irrational and often inadequate feeding is then substituted, favoring digestive disturbances, nutritive diseases (Mann and Payne's *cdema* disease), and cachexia. These troubles will serve, then, as the starting point for serious dystrophies of a slow but fatal course. The very children of school age are employed at farming tasks and frequently kept at home for the most pressing work of the season.

With the exception of chronic neph-

ritis, the most common diseases among our peasants are of an infectious nature and preventable through social medicine and hygiene.

In our rural districts intestinal infections are common, especially among children, and for the most part take the form of dysenteries or enteritis. These dysenteries may be caused by bacilli (Flexner, Shiga), and in that case belong to the epidemic type, known in Haiti as "colerin," which affects yearly about 25 per cent of our rural population. Another type is caused by the *Endameba histolitica*, being rather prevalent in the north and affecting more or less, according to the region, from 10 to 20 per cent of our country people. Other organisms with a similar pathogenic rôle are a species of infusoria, the *Balantidium coli*, and intestinal worms.

The enteritis, less serious but just as prevalent, are caused by a species of monilia; by protozoa, *Giardia*, *Chilomastix*, *Trichomonas*; and by intestinal worms, such as *Necator americanus*, *Ascaris*, and *Strongyloides*. Their cause may also be a sudden chilling, poor food, and abuse of alcohol, and in children, ill advised nursing or premature weaning. In this special field there is much work to be performed by medical science endeavoring to teach mothers proper methods of child care.

Children sometimes are apt to eat dirt (geophagism). This habit, derived from the lack of certain dietetic elements, may be said to favor intestinal infestation through the swallowing of eggs or larvae of the worms from the ground. These intestinal parasites are very common and cause many diseases, especially among children. They are also a contributing factor in weakening adults. The most common are ascaris, oxyuris, trichuris, ankylostoma (*Necator americanus*), *Strongyloides* and taeniae. In 1925, among 4,439 persons examined in the Carrefour, Rivière

Froide, and Dégand districts, we found: in 30 per cent, ankylostomas; in 43 per cent, ascaris; and 58, trichuris.

Hookworm disease is common in the sugar cane, coffee, and other plantations. The proportion of infested persons in the mass of Haitian people examined so far is 26 per cent. The prevalence and seriousness of the infestation vary a great deal in the different places. The Cul-de-Sac plain is free from the disease because the larvae of the *Necator americanus* do not develop in salty ground, but all our mountain districts are infested. This condition has been well known in Haiti since the colonial period under the name of "stomach trouble." The persons most in danger of contracting it are those in direct contact with the hot and damp larvae-infested ground, such as cane, banana, cocoa, coffee, tobacco, and rice plantations. Levacher, in his "Guide Médical des Antilles" published in 1847, states that "its appearance may be due to the clearing of virgin lands, to the opening of ditches . . . and to a watery and vegetable feeding." The slaves became infested by dirt eating, and killed themselves by the slow torture of hookworm disease. "I have seen negroes," Levacher states, "to poison themselves in this way, compelling their children to follow their example, purely to revenge themselves and with the sole purpose of hurting their owners' interests by getting out of condition."

Since that time the significance of hookworm disease has remained ignored in Haiti, and only after the first efforts made by the Rockefeller Mission (1924) to penetrate our country districts, and the opening of the first country dispensaries, was it that the Public Health Service began its campaign against one of the causes undermining our national energy. In order that this campaign might secure its best results it should be completed with a

series of sanitary measures. It is not enough to advise wearing of shoes, since the larvae scattered on the ground by fecal matter may occasionally infect even well-shod people. The menace involved in hookworm disease will decrease only when general conditions are improved and preventive medicine makes further progress.

New growths of all kinds are common in Haiti. Uterine fibroids reach sometimes considerable size. Lipomas and keloids are not uncommon. Cancer is just as prevalent as non-malignant growths but seldom diagnosed. Malignant tumors cause an approximate death rate of 5 per cent in the hospitals of the country. From a study by R. M. Choisser, it may be seen that among 700 necropsies he found 27 malignant cases, that is, 3.8 per cent (3 sarcomas and 24 carcinomas). In a series of 486 biopsies from different groups, 75 (15.4 per cent) were malignant growths, namely: 32 adenocarcinomas, 24 squamous cell carcinomas, 5 basal cell carcinomas, 3 pigmented melanomas, 3 non-pigmented melanomas, 2 lymphoblastomas, and 6 fibrosarcomas. This shows that cancer is just as prevalent as in other countries, even in the temperate zone.

Goiter is common in our mountain districts. Pellagra is occasionally found but it is not very prevalent. Granular conjunctivitis affected, according to Dr. James Hooker, 16 per cent of the children examined during the investigation carried out by the Rockefeller Foundation. Chickenpox, influenza, and cerebrospinal meningitis caused, in 1929, many deaths throughout the republic, but especially in the north.

A condition rather common in the Cul-de-Sac plain, in the Despuiseau region, is gusarola (pinta. carate), characterized by patches assuming different colors. As it also happens with other dermatomycoses, lack of cleanliness contributes to its development.

The course of the disease is very slow. Uncovered parts of the body are the first to be attacked. The white and violet varieties are those most prevalent. Several varieties may be seen in the same individual, and the patient's appearance in such cases is very peculiar and most striking. The infection is accompanied by a very annoying itching. Its etiology has not been definitely determined. While some writers believe the pathogenic agent is a fungus, this of late has been questioned (cf. *Bol. Of. San. Pan.*, May, 1934, p. 458).

Tuberculosis is rather common in our country districts. While not strictly a tropical disease, it progresses very rapidly in our country, recalling the childhood type tuberculosis of the temperate zone. The spread of this disease in our rural districts may be explained by the absence of a specific immunity in the people, which makes them more sensitive to the infection. Promiscuousness is another factor playing an important rôle in the tuberculization of the people. In the hospitals of Haiti tuberculosis is the most important cause of death, *amounting to 30 per cent of the total number of deaths!*

If we recall that a sample of milk from the Taifer section (Port-au-Prince district) contained 1,600,000 bacteria per c.c., when at the most there should have been only 10,000, and none of them of a pathogenic type; that watering the milk is an everyday affair in our rural districts; that even spring water is at times polluted by all sorts of excreta; it is easy to understand why typhoid fever claims numerous victims, especially in the colder regions, in spite of the immunity derived from repeated mild infections. This disease often exhibits an atypical course and is generally complicated by malaria. Paratyphoid fevers are also quite common.

Malaria has been known in Haiti since the discovery of the island.

Robertson and Abbé Raynal have left us interesting descriptions. Columbus, during his second trip, contracted a violent fever which left him in a comatose condition (a typical manifestation of malignant tertian due to *Plasmodium falciparum*). This is what French physicians of the colonial era called intermittent cerebral pernicious fever. Tertian and double tertian fevers, even now called acclimatization fevers, were very common during the colonial period.

Among 4,439 persons examined in different places during the surveys of the Rockefeller Mission, 67 per cent showed malarial parasites in the blood. Wilson and Clark, while examining at Port de Paix 11,000 emigrants coming from different districts in the north and northeast on their way to Cuba to work for the United Fruit Company, found that 23.5 per cent had malaria. In Haiti two species of anopheles have been identified as malarial carriers: *albimanus* and *grahamii*.

Filariasis is found mostly in the Cul-de-Sac plain and in the Quartier-Morin region. As is the case with all parasitic diseases, it may be present in apparently well people without exciting any complaint. As a rule, however, it produces repeatedly more or less serious lymphatic disturbances and many times it is the cause of elephantiasis. The filarial vector in Haiti is the *Culex quinquefasciatus*.

A disease which has become a menace among us is leprosy. This condition seems all the more serious since, in spite of the marked improvement secured almost universally through modern therapeutics, there is no leprosarium in Haiti and many cases remain untreated, and at large.

The most common disease in our country districts is yaws. Among 2,564 persons examined in different districts in the neighborhood of Port-au-Prince the Rockefeller Mission found 78 per

cent affected with yaws. The disease is common among the young. Among 3,289 cases examined by Dr. Wilson, Dr. Mathis, and the writer while the traveling clinic stayed at Nouvelle Touraine, Marché Lamarque and Berly in 1929, 61.1 per cent were children under 10. The disease made its appearance in Haiti with the introduction of the first African slaves in 1509 (cf. Sydenham: "Opera Medica," Vol. 2, p. 33, 1850 edition, and Levacher, *supra*, p. 280), but it is only since 1922 that a rational and intensive treatment has been introduced in our rural districts. The first description of this disease is accurately given by Oviedo y Valdés in 1526 in his "Historia general y natural de las Indias," where he calls it a terrible pustular disease. About 235 years ago, Father Labat wrote in his "Travels to the Islands of America": "The Caribs are very sensitive to yaws. This disease is proper of America and natural there. All those born there, of either sex, are attacked, perhaps since they come into this world, even when their parents are quite healthy or anyhow they seem to be so."

The Haitian Government has already spent enormous amounts in combating this disease. Public education and intensive treatment in some districts have been successful in reducing the number of patients. In the Jacmel region alone, from May, 1925, to April, 1926, 167,267 cases of yaws were treated. In 1926, over 200,000 injections of arsenicals against the disease were given throughout the Republic. During the fiscal year 1928-1929, 190,000 injections were given, and from 1918 to 1931 the injections given by the Public Health Service make a total of 2,655,386. At present the campaign against yaws continues in the rural dispensaries with the routine use of stovarsol or spirocid in tablet form. These drugs were put in use when the traveling

clinics were opened in May, 1929, substituting the other arsenical preparations and bismuth. From 1929 to 1930 over 300,000 tablets were given.

The wonderful central plain, known by Moreau de Saint-Méry under the name of Guaba plain, represents approximately one-tenth of the total surface of the Republic of Haiti. While fruitful and well irrigated, its population sees its earning capacity curtailed by the morbid triad of malaria, hookworm disease, and yaws. The importance, from a sanitary standpoint, of the new hospital at Hinche in this region may be understood when one remembers that this central plain must become some day the granary of the Republic.

The Public Health Service, organized in 1919, has come to remedy a sad condition and has not stopped for one day in offering to the peasants, in the shape of object-lessons and demonstrations, practical hygienic information, at every place where a permanent group of people, as a market or a chapel, may be found. It has also organized dispensaries throughout the Republic to extend its beneficial influence. However, there is still much to be done.

The Public Health Service is carrying out slowly and methodically, a hard civilizing task, the medical education of the masses, thereby leading them further and further from the old empirical beliefs.

Fireworks Study

A NATION-WIDE study of the nature, causes, and results of fireworks accidents was inaugurated July 5 by the American Museum of Safety with the coöperation of public health authorities and safety organizations throughout the country.

The study will seek to ascertain how serious a hazard to life, limb, and sight fireworks are, which particular items of fireworks are involved in most accidents, what influence, if any, prohibitory legislation has on the frequency of fireworks accidents, and the sources of the fireworks causing accidents. The study will be under the direction of Dr. Leland E. Cofer, former Director of Industrial Hygiene for the State of New York, and former Assist-

ant Surgeon General of the U. S. Public Health Service. Dr. Cofer will be assisted by representatives of national agencies all of whom have had acquaintance with the problem of fireworks accidents and who now constitute the Fireworks Accident Prevention Committee of the American Museum of Safety.

The leading fireworks manufacturers, through Pyrotechnic Industries, Inc., have not only made an unconditional grant to the Museum of Safety which will make possible a wholly objective study, but have agreed in advance to take steps for the elimination of those elements in fireworks manufacture which are shown to be responsible for serious hazards to life and limb.

Sewage Contaminated Irrigation Water

A Major Public Health Program in the West*

EDWARD N. CHAPMAN, M.D.

Colorado Springs, Colo.

ONE of the marks of civilization is the proper disposal of human excreta. It is human excreta which carry the germs of infectious intestinal diseases, which we may well call the filth diseases because they are transmitted through human filth. They include typhoid fever, amebic and bacillary dysentery, and so-called "infectious diarrhea." Where they are present one will find conditions permitting the contamination of water, milk or other food with urine and intestinal contents. Where this contamination does not occur this group of diseases does not have to be seriously reckoned with.

What is sewage? I am amazed to find how many people think of it in terms of dishwater and storm sewers. In reality sewage contains: urine, sputum, feces, disintegrated toilet paper, disintegrated sanitary pads, and contraceptive devices. Look at your sewer outlets if you live in a town not equipped with a treatment system and convince yourself of these facts.

When sewage comes in direct contact with food or domestic water we have epidemics of intestinal disease. Chicago has furnished us with two graphic illustrations of this within the recent past. A group of experts commissioned to investigate the recent amebic dysentery epidemic there re-

ported¹ that it was not caused by food handlers, as was suspected at first, but rather from the bursting of sewage pipes in the cellar of one of the leading hotels. The contents flooded the kitchen, food and refrigeration compartments of this hotel. Plumbing cross-connections, which never should have been permitted by health authorities, carried the ameba to a neighboring hotel. Even this short exposure to germ laden sewage was enough to start an epidemic the last of which has not been heard.

The second instance was during the stockyards fire in May, 1934. Sewage contaminated water was used for fighting the fire and for drinking purposes by some of the firemen and spectators. There followed among these, 69 cases of typhoid fever, 2 of paratyphoid, and many of acute diarrhea. Laboratory studies revealed that a high percentage had become infected with *Endameba histolytica*.²

Can danger to the public health result from pouring untreated sewage into streams used for irrigation? and, if there is danger in this procedure, how much does it amount to? The answer is an important one particularly to the inhabitants of our arid western states where irrigation is essential to the raising of all market produce.

Lest, in the light of present knowledge, in posing this question, I seem to set up a straw man merely to knock him down, let me state that many of

* Presented at the General Session of the Annual Meeting of the Arizona Public Health Association, Phoenix, Ariz., April 23, 1935.

our cities and towns in the West dump their sewage untreated into nearby streams—streams used in many instances almost immediately to irrigate market produce. In less populated districts, where sewerage systems are infrequent, privies will be found located directly over irrigation ditches in order that the output may be carried away easily to some neighbor's field. Man, like his mother, Nature, acts generally along lines of least resistance. These methods of disposal have aroused only rare objections and then, as a rule, from some farmer who has found the odor more than he can bear. Farmers as a class have made no complaint for they have wanted the water content of the sewage added to their scanty sources of supply and also, frequently, they receive a continuous source of fertilizer—human excreta—without cost. They have failed to realize that the buffalo gnats, which pester and sometimes kill their cattle, breed in quantities as a direct result of stream pollution. A leading newspaper with a large circulation in the West, located in one of our large cities the sewage of which is disposed of under these conditions, recently told its readers in glaring headlines that a sewage disposal plant was a waste of money and editorially advised its readers to vote against any such unnecessary expenditure. This problem then is not one made of straw, but is very real and vital.

Our methods of pouring untreated sewage into small streams and rivers carry the germs of disease and often the solid constituents of sewage into irrigation ditches to deposit them on the hands of the workers, on the soil of the fields, and on the vegetables growing in these fields. Examine some of these ditches and fields, especially those below our larger cities not equipped with adequate disposal plants. The sight is nauseating. That the grossest kind of pollution is possible under this system

is shown by the fact that lettuce has been served in public eating places with feces adhering to the leaves.

Analysis of vegetables raised with sewage contaminated irrigation water has been made in the bacteriological laboratory of the Colorado State Board of Health.³ Even vegetables which are grown many miles below the source of pollution were found to reek with colon bacilli, and after thorough washing the colon bacillus index in many instances was too high to pass them as fit for human consumption. Mills, Bartlett, and Kessel⁴ have shown that pathogenic bacteria may persist on the surface of fruits and vegetables kept under moist conditions for 15 days or more. If these bacteria gain entrance through injured or decayed portions they may remain alive 7 to 42 days. These are the vegetables that come into our markets, are handled by our housewives, and eaten by our people.

Is it possible that I am unduly exercised over the unesthetic side of this picture? Even though the chance for infection exists, may we not be fortunate enough to escape infection? Is there any real evidence to show that, after all, people living in regions where these methods of disposal are the rule have more than their share of the filth diseases?

Colorado offers an excellent laboratory for study because this is a state in which there is extensive irrigation, some of it done with water grossly contaminated by sewage and some of it with water which is relatively clean. Let us look at the death rates from some of the intestinal diseases for this state and compare them with those of the United States, the neighboring states, and California, which has a larger percentage of Mexicans and foreign born than Colorado. These figures are based on the latest statistics of the U. S. Public Health Service, and cover as long a period as is on record for

TYPHOID FEVER

Average Annual Death Rate per 100,000 Population

this group of states as a whole. California is included because this state also has extensive areas under irrigation; but the use of contaminated water for the raising of market produce is not permitted.⁵ Nebraska and Wyoming have no counties where sewage contaminated water is used.⁶ Utah and Kansas each have 1 county using contaminated water for irrigation.⁷ I was unable to get comparable data for Arizona and New Mexico which have been in the U. S. Registration Area too short a time. Such figures as I was

able to obtain would make one suspect that they are faced to even a greater extent with the same problem that exists in Colorado.

Charts I and II illustrate these comparisons. The death rates from diarrhea are especially high among babies and young children. Infants are most susceptible to contaminated food and this death rate is always a very delicate indicator of contamination. Not only are our death rates high in Colorado, when compared with those of the United States, our neighbors,

and California, but we have failed to show the percentage decline which they have shown in recent years.

Something is evidently wrong. It is not the general level of the intelligence of the population. Colorado, in a study⁸ based on 7 different tests, was rated among the first 10 states in this country in the matter of intelligence of its people. It has not as large a percentage of Mexican or foreign born population as has California, yet California has a much lower death rate from these filth diseases.

Fortunately for the purpose of our analysis, though not for economical administration, Colorado is divided into 63 small counties. Using figures for the total number of deaths from typhoid fever and from "diarrhea and enteritis under age 2," I have calculated the death rates for each of the counties and averaged them for the 3 year period 1929-1931, the latest that can be compared with the group of states already illustrated. These figures appear on Maps I and II. Counties are black which had an average death rate for this period higher than the average for the United States. Black dots mark the location of the principal

towns and cities in the state which pour their sewage untreated into streams, the water from which is used for irrigation. Without knowledge of my results, B. V. Howe, Colorado State Sanitary Engineer, indicated the streams in the state which he regarded as grossly contaminated with sewage and these I have included.

The maps graphically illustrate that, with very few exceptions, the high death rates from typhoid fever and diarrhea and enteritis under 2—some of them almost 10 times the average for the United States as a whole—occur in counties where irrigation water is grossly contaminated by sewage. Counties, whose irrigation water is relatively clean or where there is no irrigation, have, with very few exceptions, low death rates. Many of them have had no deaths from these diseases during the 3 year period. Deaths from dysentery and from "diarrhea and enteritis over age 2," in general follow this same distribution.*

Not only are death rates from the filth diseases high in most of these counties where raw sewage is mixed with irrigation water, but also every summer and fall, about the time most of the local grown vegetables come upon the market in all of these areas for which we have data, there is an epidemic of diarrhea. These epidemics used to be frequent in eastern cities. Correspondence with boards of health of some of these cities reveals the fact that they are now largely unpleasant memories of the past, thanks to improved methods of sanitation.

Granted that these diseases are problems only where sewage is spread over the landscape as we do through

* Sagauche County, which gives the appearance of being an exception to the rule, has much irrigation. The water table is unique in this county as it is only 2-3 feet below the surface of the ground. This permits contamination of domestic water supplies from privies—the common method of disposal in this county. Privies are also located directly over irrigation ditches in some instances.

the medium of irrigation water, still can we be sure that we have found the cause of our trouble? Cannot a poor domestic water supply furnish the explanation for this unfortunate condition? A recent survey⁹ of the domestic water supplies in Colorado by the U. S. Public Health Service gives the state a reasonably good bill of health. In general the supplies of the large cities are well protected, yet most of these large cities with good water supplies have a high incidence of intestinal disease. Hence domestic water transmission is not the answer.

What about milk? This same report of the U. S. Public Health Service showed that there is only a 64 per cent compliance by milk producers as a class with regulations recognized as necessary for the marketing of wholesome milk. Dairies are poorly screened. Pasteurization is often improperly performed. This situation, however, is, with a few notable exceptions, a uniform condition throughout the state, and if it alone furnishes the

explanation for our high death rates, we should expect that most of our county rates would be high. This is not what we find, as the maps indicate. Poorly safeguarded milk in the sewage contaminated counties can be particularly dangerous. Cows frequently wade in polluted water, contaminating their udders and thus the milk. Occasionally farmers use irrigation water for washing utensils. Flies can breed in deposits in irrigation ditches and then fly into unscreened dairies to transmit intestinal bacteria to milk.

What foods raised with sewage contaminated water should be avoided? Fruits, such as strawberries, which grow close to the ground; vegetables eaten raw, such as lettuce, cabbage, celery, green onions, carrots, radishes, and parsley. We have seen already that thorough washing cannot be depended upon to make them fit to eat. Cooking will destroy intestinal disease producing bacteria, but the handling by the housewife of the vegetables preparatory to cooking, or their presence in the refrigerator, may furnish an opportunity to transmit these bacteria to other foods. This is especially dangerous when articles of food intended for infant consumption are contaminated. It is as though the head of cabbage,

TYPHOID FEVER

DEATH RATE PER 100,000
1929-31 INCL.

for instance, were covered with black sticky tar. It cannot be handled without transferring the tar to the hands and to everything later touched, which may include the baby's mouth, his toys, or his food.

All this sounds almost unbelievable in a civilized community, yet it does exist, not only in Colorado, but in other states in the arid region of our South and West where irrigation is necessary. It is the sort of thing that one finds in a more aggravated form in China, where intestinal disease is rampant and American tourists are warned to avoid all green vegetables. In certain European countries human fertilizer is used on gardens, but only after proper curing, thus killing disease producing organisms. Ordinary animal fertilizers do not carry the germs of human intestinal disease.

This condition among us has persisted because the majority of thinking people, the sort of people who are sensitive to matters of hygiene, have not realized that it existed. I am convinced that all that is necessary to end this repellent situation is to inform the people of the facts. This is being done in Colorado under the active leadership of the Committee on Public Health of the Colorado State Medical Society and the Colorado State Board of Health. Boulder has just completed a sewage disposal plant. Denver, Colorado Springs, and Greeley, within the past month, have voted bonds for this purpose. With these progressive communities leading the way it will not take long for other cities without proper sewage disposal to fall in line.

The government has shown that it is ready to assist financially with grants under the P.W.A. in the improvement of sanitation throughout the country. Cities in many eastern and Pacific coast states are building sewage treatment plants to protect streams and rivers which are used only for naviga-

tion, bathing, and fishing. How much more important it is that we should protect our streams from sewage pollution. Irrigation water does not need to have the purity of domestic water unless it is used for domestic purposes, but it must be protected against gross contamination. The California regulations, too lengthy to discuss in this paper, seem sane and practical. Remember, however, that regulations are worthless unless the people want them enforced.

The solution is one of education. We, in this dry section of the United States, where irrigation is necessary, must separate our food from our feces, if we are to rid ourselves of our high

DIARRHEA + ENTERITIS
UNDER 2
AVERAGE ANNUAL DEATH RATE
PER 100,000
1929-31 INCL.

incidence of the filth diseases. It is the duty of all who are leaders in public health in the West to investigate this problem as it applies to their own states, and then to carry to the people the facts. Our people, once informed,

can be depended upon to take the steps necessary to end this dangerous and revolting condition.

Aerial Navigation

ON June 5, 1935, the United States Senate ratified, with two reservations, the International Sanitary Convention for Aerial Navigation, which was opened for signature at The Hague, on April 12, 1933, and signed on behalf of the United States on April 6, 1934.

Two reservations were made: 1. Exempting the United States from liability to amendments unless they were first accepted by the government; 2. reserving the right to decide as to whether or not a foreign district is infected and also what requirements shall be applied.

"The ratification will have to be deposited with the Government of the

Netherlands before the convention is proclaimed by the President. The convention provides that as soon as 10 ratifications have been deposited, the Government of the Netherlands will draw up a procesverbal and transmit copies to the Governments of the high contracting parties and to the Office International d'hygiene publique, and the convention shall come into force on the 120th day after the date of the procesverbal. Ten ratifications have already been deposited with the Netherlands Government, and the convention will come into effect on August 1, 1935." —*Pub. Health Rep.*, June 28, 1935, pp. 863-864.

Outbreak of Food Poisoning, Probably Due to *Staphylococcus Aureus*

A. CORPENING AND ELSIE P. FOXHALL

Bureau of Laboratories, State Department of Health, Richmond, Va.

TWELVE people were involved in a food poisoning outbreak following a dinner at which cake with custard filling was served. A local physician made a study of conditions and found that only the people who ate the cake became ill. The State Epidemiologist inspected the kitchen where the dinner was prepared and found it clean and sanitary. The pantries and refrigerators were also remarkably clean. The cooks and helpers were well and gave no history of having been ill during the previous month.

Two cakes with a custard filling were made Friday morning, September 7, one of which was served for luncheon on Friday, but no one became ill following this luncheon. The other cake was placed in the refrigerator that afternoon. Saturday morning it was taken out of the refrigerator and left at room temperature until it was served that night, September 8, for dinner.

The people who ate the cake that evening became ill within 3 or 4 hours after eating. Nausea, vomiting, griping abdominal pain, diarrhea, and prostration were the outstanding symptoms. One patient had, in addition, some disturbance of vision and violent cramps in his leg muscles. It was necessary to administer morphine to quiet him. The illness persisted in some cases 3 or 4 days. No deaths occurred.

A portion of the cake and custard filling was sent to the laboratory 3 days

after it was made. Since the cake also contained the custard filling, we will refer only to the cake. A direct microscopical examination showed the presence of staphylococci and large Gram-positive spore forming bacilli. Some of the cake was emulsified in sterile saline and inoculated on dextrose agar and eosin methylene blue agar plates; also in 1 per cent dextrose broth, veal infusion and beef infusion broth.

Animal experiments were made with portions of the cake. No ill effects were produced in rabbits or guinea pigs following the intraperitoneal injection and feeding of portions of this cake.

The bacteriological examination of the cake showed 4 types of organisms: *Bacillus subtilis*, *Streptococcus fecalis*, *Staphylococcus aureus* and a Gram-negative bacillus belonging to the Eberthella group and corresponding to *Eberthella enterica* (Bergey's classification). Three of these organisms, *Streptococcus fecalis*, *Staphylococcus aureus* and *Eberthella enterica* were tested for toxin production. *Bacillus subtilis* was not included, as we know of no instance in which *Bacillus subtilis* has produced food poisoning. For toxin determination a medium similar to the custard filling was prepared and divided into three 2 oz. portions. One portion was inoculated with 1 c.c. of a broth culture of the *Staphylococcus aureus*, another portion with 1 c.c. of a broth culture of the *Streptococcus fecalis* and the

third portion with 1 c.c. of a broth culture of the *Eberthella enterica*. The portions were fed to cats after 48 hours of incubation at 37° C. Each cat consumed approximately 1½ oz. of custard. There were no noticeable effects. Three 1 oz. portions of minced beef, to which was added 1 c.c. of a 48 hour broth culture of each organism, were fed to cats. There was no evidence of illness. A 24 hour culture of the organisms inoculated into beef infusion broth was fed to cats. The cat fed the *Eberthella enterica* culture did not show any evidence of illness; the one fed the *Streptococcus fecalis* developed diarrhea within 5 hours; the one fed *Staphylococcus aureus* appeared to be nauseated within 6 hours, but did not vomit. The cats were kept under observation 4 days,—all remained alive and were well at the end of this time.

Further studies for determining the toxin production of the organisms were conducted with rabbits and mice. Forty-eight hour bacterial-free broth filtrates of each organism were inoculated intraperitoneally into mice, but caused no evidence of illness. A rabbit inoculated intravenously with 1.5 c.c. of a 48 hour bacterial-free broth filtrate of *Eberthella enterica* died 1¼ hours later. A second rabbit inoculated intravenously with 1.5 c.c. of a bacterial-free filtrate of a 48 hour broth culture of *Eberthella enterica* developed a slight diarrhea within 1 hour. Two rabbits inoculated intravenously with

1.5 c.c. of a bacterial-free filtrate of a 48 hour broth culture of *Streptococcus fecalis* and *Staphylococcus aureus* did not show any evidence of illness. One and five-tenths c.c. of a bacterial-free filtrate of a 96 hour broth culture of *Staphylococcus aureus* and *Eberthella enterica* injected intravenously into rabbits failed to produce illness. Two c.c. of a bacterial-free filtrate of the 3 organisms grown in custard for 48 hours and inoculated intravenously into rabbits did not produce any symptoms of illness.

Further experiments were conducted with human volunteers. The results are shown in Chart I.

Blood was received from one person who had been made sick by eating the cake. A culture made from this blood showed *Staphylococcus aureus*. The culture was made from a clot and there is a question as to the etiological significance of the presence of *Staphylococcus aureus*, since a large number of blood cultures sent to the laboratory show the presence of this organism. The organism isolated from the blood did not agglutinate the patient's serum.

Specimens of feces were received from 5 persons who became ill after eating the cake. *Staphylococcus aureus*, *Streptococcus fecalis* and *Proteus vulgaris* were isolated. The incidence of these organisms in the specimens was no more than would be expected from any fecal specimens.

The *Staphylococcus* isolated from the

CHART I

RESULTS OF INGESTION OF BACTERIAL-FREE FILTRATES BY HUMAN VOLUNTEERS

Human Volunteer	Type Filtrate	Organism	Amount	Results
A	48 hr. broth	<i>Eberthella enterica</i>	5 c.c.	No ill effects
B	48 hr. broth	<i>Staphylococcus aureus</i>	5 c.c.	No ill effects
C	96 hr. broth	<i>Eberthella enterica</i>	20 c.c.	No ill effects
D	96 hr. broth	<i>Staphylococcus aureus</i>	20 c.c.	Nausea, vomiting, diarrhea
E	96 hr. broth	<i>Streptococcus fecalis</i>	20 c.c.	No ill effects
F	48 hr. custard	<i>Eberthella enterica</i>	6 c.c.	No ill effects
G	48 hr. custard	<i>Staphylococcus aureus</i>	7 c.c.	Nausea, diarrhea

Control tests were made with normal filtrates in each instance.

food produced a yellow pigment. The morphology was that of a typical coccus, occurring singly, in pairs, and in clumps. Dextrose, lactose, maltose, mannite, and sucrose produced acid but no gas. Salicin and inulin were not affected. Gelatin was not liquefied. Litmus milk was rendered acid, but coagulation did not occur. A 96 hour beef infusion broth culture heated to 100° C. for 15 minutes, only partially destroyed the toxic substance. A human volunteer swallowed 20 c.c. of a bacterial-free filtrate of a broth culture exposed to heat at 100° C. for 15 minutes, and while the reaction was not violent there was a slight indication of nausea and soreness of the abdomen, with occasional griping pains. This was the same person as volunteer "D" who had previously ingested 20 c.c. of a bacterial-free broth filtrate that had not been exposed to heat.

As the symptoms developed within 3 to 4 hours after ingestion of the cake it seems probable that a formed toxic substance was the active agent. The *Staphylococcus aureus* isolated

from the cake apparently produced a toxic substance in broth and in custard media as shown by the effect of the sterile filtrates, which, when swallowed by human volunteers, gave rise to symptoms resembling those of the persons made ill after eating the cake.

SUMMARY

1. Food poisoning due to cake with custard filling caused the illness of 12 persons.
2. This illness was acute gastroenteritis with nausea, vomiting, diarrhea and prostration. In the more acute cases there were severe muscular spasms. No deaths occurred.
3. Microscopic examinations of the food showed *Staphylococcus aureus* to be the predominating organism.
4. Specimens of the cake were fed to rabbits, guinea pigs, mice, and cats. There were no severe illnesses.
5. Bacteriological examination of the cake revealed 4 types of organisms: *Staphylococcus aureus*, *Streptococcus fecalis*, *Eberthella enterica* and *Bacillus subtilis*.
6. Human volunteers developed symptoms of food poisoning after drinking the *Staphylococcus aureus* filtrates. Filtrates from the *Eberthella enterica* and *Streptococcus fecalis* did not prove to be toxic when swallowed by human volunteers.

Development of Adult Type Pulmonary Tuberculosis Following the Recognition of a Childhood Form

H. R. EDWARDS, M.D.

Acting Health Officer, New Haven, Conn.

HOW frequently will an individual with a childhood type tuberculosis progress to an adult pulmonary form? This question is of considerable importance in tuberculosis administrative practice. If this progression occurs in over 2 per cent of cases, is it logical to provide the necessary facilities for adequate supervision? If such supervision is deemed necessary, then it is logical that we should make every effort to discover all cases of childhood type tuberculosis for further observation. The facilities necessary to establish and maintain the above indicated services are costly, and before adopting them we should know the approximate return to be expected from the dollar invested.

Available data in the literature on this problem is limited and not fully comparable. In New Haven, we have observed 155 children originally classified as childhood type tuberculosis—9, or 5.8 per cent of whom later developed an adult pulmonary form. We present our material with the hope that similar data may be forthcoming from other workers to assist in determining the relative importance of this control procedure with the many others more or less well established.

It has been shown by Opie¹ that on autopsy, every case of adult form pulmonary tuberculosis has an associated primary lesion. Also, it is assumed that

the presence of a childhood type lesion represents much more than casual infection. Thus, the inference adduced is that every case with evidence of a childhood type lesion is a potential case of adult form.

Pope² in reporting on 5,000 children followed in the Chadwick clinics, states:

During the period of observation, 30 new cases of pulmonary tuberculosis developed. . . . In this group the average age at which pulmonary tuberculosis was diagnosed was 15.4 years, and the mean interval from the original examination to the development of pulmonary lesions was 4 years. The proportion of cases in which pulmonary tuberculosis developed was twice as high among children with childhood type lesions as in the suspect group, 0.93 compared with 0.46 per cent. . . . Of the whole observation group during a mean period of about 3½ years, pulmonary tuberculosis developed in 0.6 per cent while the mean incidence of pulmonary disease in the total school population has been 0.1 per cent.

Hall and Chang³ reporting on 1,007 Chinese of the professional class, indicate that in 308 cases, there were changes in diagnosis over a period of supervision. Of 144 originally classified as tracheobronchial tuberculous lymphadenitis, 6, or 4.1 per cent, developed manifest pulmonary tuberculosis in an average of 54.5 months.

Korns⁴ reports that, in a group of 100 positive tuberculin children show-

ing X-ray evidence of childhood type, 2 later developed an adult type, or 2 per cent. One of these cases had remained in the home with his father who had had a positive sputum for years. The second had had a heavy childhood exposure in the home 7 years previously, but none since that time.

Rathburn⁵ states:

This type (childhood tuberculosis) is found in only between 3 and 4 per cent of the total school population of our county, which means that 50 per cent of the cases of pulmonary tuberculosis developing during the 'teens, is confined to this small group.

Stewart⁶ reports that 84 out of 10,000 children examined at Lymanhurst, 0.08 per cent had pulmonary tuberculosis. Thirty-six of the 84; 43 per cent or 0.04 per cent of the 10,000, were observed to have progressed from a childhood type to adult form. He concludes that primary tuberculosis infections do not prevent consumption from developing at some later date, and in fact predispose to consumption if successfully reinfected from exogenous or endogenous sources.

In New Haven, there have been two reports indicating the progression from a childhood type to a pulmonary form. Boles⁷ tabulated data on 127 cases previously diagnosed as childhood type in the files of the New Haven dispensary, over the period 1916 to 1929. The ages on admission were 1 to 15 years, and at the close of the period of observation, 6 to 28 years, in 1931. Fourteen, or 11 per cent, developed an adult pulmonary lesion. Contact history was definite in 11, questionable in 2, and negative in 1. Edwards⁸ in a partial analysis of tuberculosis dispensary practice among New Haven residents in 1931, revealed 105 changes in diagnosis among 2,693 examined. There were 3 originally diagnosed as childhood type who later developed a pulmonary lesion, or 0.9 per cent.

The tuberculosis program in New

Haven is based on the family unit. For purposes of continued study and analysis, every case of diagnosed tuberculosis (all forms) is carried in our files until he dies, moves away, or is lost. For similar purposes of study, we endeavor to carry every tuberculin positive child, and every childhood type disease discovered in the clinic, until the individual attains the age of 25 years.

A review has been made of the current tuberculosis family roster in New Haven, March, 1934, to determine the number of instances in which there was a progression from childhood types to an adult type. We located 155 individuals with a primary diagnosis of childhood type tuberculosis, which came within the following general classification:

1. The diagnosis of childhood type was made prior to 1932.
2. Age of individual when first diagnosed childhood type was under 18 years.
3. A definite history of tuberculosis had been made in one or more members of the family.
4. Roentgenographic evidence of a childhood type lesion.

There were 9 of the above individuals who progressed to a pulmonary tuberculosis, which was confirmed by subsequent radiographic examination.

It is of interest to consider further some of the factors involved in the 9 cases in which progression of disease was noted.

FACTORS INVOLVED IN 9 CASES

Exposure to Tuberculosis—In each of the 9 families, there were one or more primary cases of pulmonary tuberculosis. In 6 families, there was 1 case, in 2 there were 2 cases, and in 1 family, 3 cases. In addition, 1 family had also a case of tuberculous meningitis. Each of these diagnoses was made prior to the diagnosis of childhood type in the individual in this study. The tuberculous meningitis and 3 of the pulmonary diagnoses were made at

the time of death. Our records do not give reliable information as to the probable duration of illness before the date of death.

An attempt was made to estimate the exposure in days from the date of first diagnosis of the primary case to its termination in the home, either by death or removal to a sanatorium. Allowance was made for periods of hospitalization of the primary case. Three of the cases had some hospital care, but finally died in the home. There were a total of 1,942 days of exposure for the group. In 3 cases, the time ranged from 2 to 17 days, and in 4, from 509 to 686—thus an average of 242.7 days for each case.

It must be obvious that the actual period of exposure was much longer than from the time of diagnosis of the primary case, and would easily range from a few months to years, if we knew exactly the time of onset of disease in the original cases.

In each of 5 families, the primary case of tuberculosis was removed by death, varying from 2 to 10 years before the case under discussion was diagnosed as childhood type. The progression to adult form occurred without other known sources of infection in these families. In 4 families, the primary case of tuberculosis was living at the time. A childhood diagnosis was made, and in 3 at the date the adult pulmonary type was made. In 1 of the latter families, the primary case is in a sanatorium where he was admitted shortly after diagnosis.

Bacilli in Sputa of Primary Cases—In the known primary sources in the 7 families in which a diagnosis was made before death, there were 9 cases known to have had bacilli in their sputum. The pulmonary cases diagnosed at time of death undoubtedly were likewise infectious.

Hospitalization of Primary Cases—All of the primary sources in the 9

families, excepting 3, had some period of hospitalization during the period of exposure.

Deaths Among Primary Cases—Of the 13 sources of primary infection, all but 1 had died at the time this study was made. The 1 case still living has been in a sanatorium since diagnosis. Practically all of the adults have been examined one or more times during the period of supervision. There are a few children in 2 families younger than the case included in this study, that have not as yet been examined. The oldest is 10 years, and the others average under 5 years. All unexamined individuals, adults, or children, are, according to all available information from our nursing service, in good health, and would not be considered as possible sources of reinfection.

Analysis of Cases Showing Progression of Disease—Sex—There were 7 females and 2 males.

Age at Time of Diagnosis—A diagnosis of childhood type was made at an average age of 12 years, the youngest 7 and the oldest 18 years.

A diagnosis of adult pulmonary forms was made at an average age of 15.1 years. The average days between the childhood type and adult pulmonary form was for the 9 cases, 993 days, or 2 years, 8 months, and 23 days.

Bacilli in Sputa—Only 2 of the 9 cases have shown bacilli in their sputa to our knowledge.

Hospitalization—Five of the 9 cases have had some period of hospitalization during the period of supervision.

Deaths—One child who progressed to an adult form has since died of tuberculosis.

DISCUSSION

A review of the findings of certain investigators dealing with the observed progression of childhood type tuberculosis to an adult pulmonary form indicates a wide variation from 0.04

per cent by Stewart to 4.1 per cent by Hall and Chang, the latter dealing with an older age group than the former. The reports from New Haven studies vary widely from 0.9 per cent to 11 per cent. The most recent analysis of New Haven data reported herewith as 5.8 per cent differs from Boles's report chiefly in that it is confined to New Haven residents, whereas the latter covered many patients registered at the New Haven Dispensary from many adjoining communities. The only apparent reason for this variation is that Boles's cases were possibly exposed to greater infection risks than those individuals studied as New Haven residents. Since 1927, New Haven authorities have placed considerable emphasis on hospitalization of the open case; in fact, no case of open tuberculosis, once discovered, need remain in the home. In 1928, about $1\frac{1}{2}$ patients were hospitalized at all times per each annual death. By 1934, this ratio had been raised to $2\frac{1}{2}$ patients. It is known that many of the smaller communities near New Haven, and utilizing the New Haven Dispensary services, have not been favored with similar hospital facilities. The possibility of casual infection in any of these cases must be considered, though we have no knowledge of its occurrence.

In view of the fact that none of the above reported results are entirely comparable, and, further, that the percentage of progressions vary so widely, it does not seem that we have as yet reached a point where we can with any degree of surety state the administra-

tive importance or significance of the childhood type lesion.

It is important that more extensive data be collected on this problem, as it is one of fundamental importance in tuberculosis administration. If it is found that much less than 1 per cent of cases will show progression, it would not seem justifiable to set in motion extensive case-finding facilities with the costs involved to discover lesions of primary infection. If, on the other hand, the most recent experience reported herewith for New Haven is a reasonably accurate average, then we should include in our tuberculosis program the necessary machinery to detect early lesions and the necessary supervision through the danger period.

It is of some interest to note that practically all cases observed by others and referred to in this report, as well as our own, occurred among the adolescent age group.

Bacteria on Fresh Fruit

MARION M. JOHNSTON, PH.D., AND MILDRED J. KAAKE

*Research Laboratories of the Department of Paediatrics, University of Toronto,
and the Hospital for Sick Children, Toronto, Ont.*

MICROÖRGANISMS held to be responsible for infections have been isolated from fruits, such as dates and melons.^{1, 2, 3} The present report is concerned with an attempt to isolate from fresh fruits bacteria similar to the causative species which have been cultured from cases of infectious diarrhea (summer diarrhea, or gastro-enteritis) admitted to the Hospital for Sick Children, Toronto.^{4, 5}

It has been shown that flies have probably served as vectors of these colon-typhoid-dysentery species.⁵ The prevalence of flies prior to and during the seasonal period when these cases are epidemic suggested that the above mentioned bacteria might be conveyed by these insects to fruit which is abundant in the stalls during the same chronological period. The fact that such fruit is also handled by the vendor offered the possibility of contamination directly from human sources.

During August and September, 1933, 8 lots of fruit were purchased from stores located at different points in the city. This fruit was displayed for sale either inside or outside the front of the shop where it was quite accessible to insects. The vendor transferred the purchases — apples, pears, plums, peaches, crab-apples, grapes, and tomatoes—to paper bags in which they were taken directly to the laboratory. With sterile forceps, these fruits were transferred to sterile beakers in which they were washed with sterile normal

saline buffered with sodium and potassium phosphates to pH 7.0. The saline was then centrifuged and part of the sediment was spread upon Mac-Conkey bile salt lactose agar and upon blood agar plates. Sterile broth was added to the remaining sediment which was then incubated over night, after which a loop of culture was spread upon similar plates. After incubation, a large selection of colonies which presented differences in appearance were transferred to agar slopes and an attempt made to identify them culturally. The color, shape, and texture of the cultures were noted. Films from each culture were stained by Gram's method. The following tests were carried out: (1) motility, using an 18 hour peptone water culture; (2) indol, using the Ehrlich reagent after at least 5 days' incubation; (3) methyl red and Voges-Proskauer using the colon bacilli isolated; (4) Koser's citrate test; (5) gas production in dextrose peptone water only. Lead acetate, litmus milk and gelatine medium were also used. The production of acid was shown in peptone water medium containing Andrade's indicator and, separately, 1 per cent of the following alcohols or carbohydrates: lactose, dextrose, maltose, saccharose, xylose, mannite, arabinose, salicin, and raffinose.

Identification of the various species enumerated was accomplished by descriptions compiled from various sources.⁶⁻¹⁰

The following species were identified:

Micrococcus pereitrens 2 cultures

Mic. candidus 1

Staph. pharyngis 6

Staph. tetragenus 1

Staph. subflavus 6

Staph. epidermidis 3

Staph. aurantiaeus 1

Staph. citreus 2

Sarcina lutea 1

Protens mirabilis 1

Alcaligenes marshalii 31

Al. bookeri 10

Al. albus 6

Al. fecalis 10

Aerobacter aerogenes 39

Aer. levans 2

Aer. cloacae 9

B. coli communis 12

B. coli communior 1

B. oxytocus perniciosus 1

B. alkalescens 3

B. dispar 1

B. dysenteriae Sonne (?) 3

The following species grew in Koser's citrate medium: *Mic. candidus*, *Prot. mirabilis*; *Al. marshalii*, *Al. bookeri*; *Al. fecalis*; the aerobacter species; *B. coli communis* and *communior*; *B. alkalescens* and *B. dispar*.

The remaining species failed to grow with the exception of *Staph. citreus* and the *B. dysenteriae* Sonne (?) which were not tested.

Staphylococci were found on fruit from each source, and hemolysis was demonstrated by a strain of *S. aureus* isolated from one lot. *B. subtilis* which was always hemolytic was present in the cultures from all sources. Hemolysis was shown by *A. marshalii* and *A. fecalis*. In addition to the various species of *Alcaligenes* noted, 4 unidentified cultures presumed to belong to that genus were recovered. In regard to the strains which gave the cultural reactions of *B. dysenteriae* Sonne, no agglutination was obtained when they were tested with pure R and S agglutinating sera. A strain of *B. fluorescens* and 3 yeasts were isolated. Fifty cultures of unclassified proteolytic bacilli, 8 unclassified Gram-positive cocci and 33

other unidentified cultures, mainly Gram-negative bacilli, were found.

DISCUSSION

The majority of the species of bacteria identified in this study were probably of soil origin and therefore were of little significance as probable causative factors in human disease. However one strain of *B. dispar* was isolated which is held to be the cause of dysentery in man.¹¹ Three strains of *B. alkalescens* which are not considered pathogenic⁸ were obtained. The presence of members of the colon group may indicate pollution from fecal sources. *B. oxytocus perniciosus* has been isolated from soil and from the alimentary tract of humans.⁷

Gray¹² reported that *B. aerogenes* was practically universally present although in small numbers in stools of normal adult humans, but its preponderance in numbers in water over that of *B. coli* may indicate long past fecal contamination, and, as far as water is concerned, may be taken as indicating freedom on the part of the water from pathogenic microorganisms including *B. typhosus* and *B. paratyphosus* Beta.

The strains of *B. coli communis* and *B. coli communior* which were MR + and VP — grew in the citrate medium which is not in agreement with the classification of the majority of fecal colon strains according to Koser's work.¹³ They may therefore be assigned to an intermediate group which, although at times found in feces, are not normally inhabitants of the intestinal canal.⁸ Bardsley¹⁴ found:

. . . that organisms of the coliform group are not widely distributed in nature except where fecal contamination has taken place at some period more or less remote. . . . that the occurrence of *Aer. aerogenes* and the intermediate type in food supplies may be due to fecal pollution although the presence of these bacteria in the absence of *B. coli* would seem to suggest that the pollution had not been recent.

If fecal pollution of fruits by flies or human hands does occur the bacteria transferred thereto do not remain viable for a very long period. In order to test this point the following experiment was carried out:

A tomato and 2 apples placed in a sterile covered beaker were sprayed with a saline suspension of *B. dysenteriae* Sonne, and then allowed to stand at room temperature for 32 days. At intervals a sterile swab moistened with sterile broth was rubbed over the surface of the fruit and then rubbed over sterile MacConkey lactose bile salt agar. The species was obtained from the surface of the tomato up to the end of 2 days but not after 6 days; it survived for 10 but not for 18 days in the flesh of the tomato, a fissure having developed which permitted internal contamination. It was obtained for 6 but not for 8 days from the skin of an apple.

SUMMARY AND CONCLUSION

1. A study of the bacteria on the skins of fresh fruit yielded in addition to staphylococci, proteolytic and alcaligenes bacilli, 1 strain of *B. dispar*, and 3 of *B. alkalescens*.

Thirty-nine strains of *B. aerogenes*, 12 of *B. coli communis*, 1 of *B. coli communior* and 1 of *B. oxytocus perniciosus* were cultured. The coli communis and coli communior strains appeared to be of the intermediate type.

2. The presence of these species on fruit may suggest pollution from fecal sources.

3. *B. dysenteriae* Sonne persisted on the surface of tomato for at least 48 hours, and for 10 days in the tomato tissue. It was not cultured after 8 days from the skin of an apple.

A study of bacteria isolated from fresh fruit has been carried out. The presence of members of the colon and dysentery groups of Gram-negative bacilli suggests possible fecal contamination. However, no widely accepted pathogens of the colon-typhoid-dysentery group held responsible for severe summer diarrheas in infants and children were obtained.

Diphtheria in Grays Harbor County, Washington

RUTH R. LAUE, R.N., P.H.N.

President, Grays Harbor Graduate Nurses Association, Aberdeen, Wash.

THE Grays Harbor Graduate Nurses Association in 1933 was composed of a group of about 35 public health minded members, confronted with an urgent community need. At their meeting in March discussion revealed that the diphtheria situation in the county was acute and immediate action was needed. Private duty nurses found diphtheria prevalent. The Metropolitan and Red Cross nurse also had found many cases of the dread disease. A number of deaths, cases of paralysis, and heart complications had come to our notice, stressing the great need for action. These were all too often found in homes where medical and nursing care were not available, through circumstances brought about by the depression and a lack of general knowledge of the situation. The general public was totally unaware of the existence of the disease in the community, with the result that the contagion was very rapidly spreading.

The county had no funds available to combat the spread of the disease and the state had never made provision for any type of immunization. Many of the nurses had children of their own and they especially realized the need of immunization. The time also seemed opportune, as many of the nurses were unemployed and it was obvious that any work done would have to be volunteer and that materials would have to be purchased as economically as possible.

The president of the association was vitally interested in the situation. Some

one courageously made the motion "to recommend immunization and assist in the inoculation." The project was to be a county-wide campaign against the spread of the disease.

Mrs. Mae Burwell was made chairman of the project. The county health officer was enthusiastic and secured the biologics through the State Health Department at a discount. A small amount of this work done in the county a few years before gave a basis for the per capita cost.

Action followed rapidly. Letters were written to the Grays Harbor Medical Association by a committee of nurses, and each physician was called on by the committee. The members of the Medical Association voted to give their services. Coöperation of the county and city superintendents of schools was needed and they were unanimously in favor of the project. Letters, through the schools, were sent into all homes to acquaint the parents with the necessity for treatment and to ascertain the number who would wish immunization. The schools then sent out notices giving the dates of the clinics.

The project grew in scope to include preschool children, parents, and teachers. In all, 102 clinics were held and more than 5,900 persons immunized, each person receiving in practically all cases, 3 inoculations. Cards were made for each child as a record, and certificates given each by the doctor at the last clinic.

The Grays Harbor Broadcasting Sta-

tion and the newspapers also greatly assisted in the matter of arranging these clinics. Interest in the project grew. Many nurses who were married and had retired from active work became interested and gladly gave their time. Many parents, when they realized the necessity for the treatment, took their children to their family physicians for inoculation—this made many immunizations of which the nurses' Association had no record—showing the educational value was far reaching, as immunization was discussed in every home in the county.

Sixteen doctors volunteered their services and an average of 5 nurses attended each clinic. Transportation was necessary as the county is larger than some of our New England States and in several instances necessitated a 50 mile drive. The county was restricted and small rural schools were grouped. Doctors and nurses started at the schools farthest away and worked their way homeward. Teachers gave their time and service willingly.

Standardization of materials and equipment was impossible, as each doctor employed his own technic, with which the nurses complied. Sterilization of equipment was not the least of the problems confronting the nurses. Some of them having steam pressure cookers and others having electric hot plates, assumed the responsibility of sterilizing the equipment for the clinics.

Dates for the clinics had to be made to meet the convenience of the doctors and the schools, both public and parochial.

Financing the project proved to be the biggest problem. So anxious were nurses and doctors for the immunization that they failed to stress the necessity for each person treated to contribute the small fee of \$.25. The cost of all correspondence, long distance telephone calls, drug supplies, equipment, as well as some laboratory expense for throat

cultures, and a part of the transportation, was paid by the nurses.

The American Legion Auxiliary assisted by having some one present at many of the clinics to receive the fees. They took charge of this money, and paid bills as long as the funds lasted. They also gave \$25 to the project.

The Orthopedic Auxiliary assisted with the transportation, providing cars and drivers. The Crescent Orthopedic assisted financially by contributing \$10.

The public became conscious of the need and were anxious for immunization, but the project grew to such proportions that it became too burdensome for volunteer labor, and had to be abandoned. Had there been funds available, county-wide immunization for smallpox and more diphtheria immunization could have been accomplished. Parents were invited to the clinics and doctors dispensed information willingly, answering many questions—thus the clinics truly were an unprecedented opportunity for public health education.

When the last clinic had been held, schools closed for the summer, and the last money turned in, the bills received showed a deficit of \$312, which did not seem a large amount when compared with the total cost of the clinics, approximately \$1,214, but it looked tremendous when faced by the Grays Harbor Nurses Association. A dance was given which netted a profit of \$57. Each school which had not paid was written to in the fall when school opened, but this availed little, though one city school collected \$22, one parochial school \$10, and a few schools sent small warrants. These, with the contributions mentioned brought the total debt down to \$188. The County Commissioners, who had promised the County Health Office to help if there were a deficit, were then approached, and very graciously agreed to pay this balance.

These troubles were small when compared with the gratifying results accomplished.

The effectiveness of the project can now be determined by the report from the State Department of Health, dated April 4, 1935, which is as follows:

<i>Diphtheria</i>	1933		1934	
	<i>Cases</i>	<i>Deaths</i>	<i>Cases</i>	<i>Deaths</i>
Grays Harbor County	5	1	2	..
Aberdeen	41	2	8	..
Hoquiam	14	2	2	..
Totals for county	60	5	12	0

In addition we are positive that many cases were not detected or reported to the Department of Health.

We have no record of any lasting harmful effects occurring in these clinics from the use of the "Toxoid."

NOTE: Were it possible, we would like to make special mention of many who contributed their time and special abilities, without which a project which involved so much detail and work could not have been carried out so successfully, and been made so pleasant.

Tacoma, Wash., Makes Progress

THE first free health survey in connection with the City Health Conservation Contests was awarded to Tacoma, Wash., and made in the fall of 1934.

Dr. Atwater, Executive Secretary of the American Public Health Association, was in Tacoma on July 10 and observed many worth while results of the survey. An excellent health council with splendid representation of all organizations has been organized. Definite improvement has been effected in the field of vital statistics and in venereal disease services, under Dr. S. M. Cresswell, City Health Officer. More effec-

tive coöperation with the school medical service is reported, with some 9,200 vaccinations. Tacoma Junior League provides a secretary for the Health Council. A very effective committee on public health education under the direction of Dr. Whittaker is working closely with physicians and dentists, among whom classes in effective public speaking are being organized. It is reported that the Western Washington Fair Association has given the Tacoma Health Council a permanent assignment of space for regular exhibits and has placed in its hands the censorship of all health, food and drug exhibits.

Flipping Device for Flange Rubber Stoppers

V. T. SCHUHARDT AND J. H. BREWER

*Assistant Director, and Bacteriologist, State Department of Health Laboratories,
Austin, Tex.*

THE advantages of the flange type rubber stopper for the safe distribution of various bottled biological products are obvious. The difficulty of flipping the flanges by hand during the process of bottling, however, renders the use of this type of stopper almost impossible, especially if rubber gloves are worn. Since we were not aware of any device on the market for performing this rather simple but important act, we decided to develop a mechanical flipper for our use in the laboratory.* The instrument has proved so thoroughly satisfactory that we feel it might be of value to others who are producing biological products.

The device is built of bronze and consists of four movable arms pivoted

FIGURE II—Method of Operating Mechanical Flange Flipper

FIGURE I—Sectional Views of Flipping Device

at the center and sliding into a tubular base. The spreading action is obtained by a double cam arrangement. The first expansion is obtained by forcing the beveled nose-piece of the instrument down between the four arms, each of which is beveled at the top on the inside. The expansion is completed by

* We wish to give credit and express our appreciation to J. R. Blocker, machinist at the University of Texas, for perfecting and building the instrument.

the cam action due to the outside bevel at the bottom of the arms sliding down the bevel on the inside of the tubular base. This double expansion spreads the top of the arms sufficiently to encircle completely the lip of the bottle. As the arms move downward the edge of the stopper flange comes in contact with the top of the flippers. The latter consist of four bent strips of spring brass which are attached to the base and fit snugly against the outside of the movable arms. The continued downward movement of the bottle causes the flipping of the stopper flange. The flippers then slide on over the lip and

stretch the flange into place around the neck of the bottle. With the release of downward pressure two springs force the arms and nose-piece back to their resting position. One of the arms travels through a groove in a bent strip of bronze fastened to the base. This prevents rotary movement and keeps the arms in position relative to the four fixed flippers.

By varying the length and size of the arms and flippers and the circumference of the nose-piece an instrument can be made to use with any of the larger size serum bottles and flange stoppers.

A Neglected Opportunity for the Control of Respiratory Disease*

HOMER N. CALVER, F.A.P.H.A. (*Life Member*)

*Secretary, Public Health Committee of The Cup and Container Institute,
New York, N. Y.*

EVERY health officer at some time feels that he is like a juggler, keeping a dozen different things going in the air at the same time or balancing a variety of programs on the end of his nose. The wise health officer does not attempt to juggle everything at once, lest the whole collection come tumbling about his head. Instead, he varies his program from time to time, pushing first a diphtheria campaign, later the early diagnosis of tuberculosis, a child health day, or a summer roundup, or something else. Thus in the course of a year he has kept his whole program alive, kept his staff interested, and reaped public approbation through the newspaper support which can be given to special campaigns but is more difficult to get for routine activities.

Emphasis in public health programs changes like women's fashions. A new discovery, pressure waves from voluntary groups, enthusiasm of a specialist, sweep our activities this way and that, mold our efforts and force the Cinderellas of our program to the background while the more popular sisters shine in the light of current professional acclaim.

On what then can the health officer base his selection of activities? There is, of course, the *Appraisal Form* of the

American Public Health Association, and no health officer should attempt to run a health department without this as his constant guide; yet this document through its changing editions, reflects the changing favorites in our public health esteem.

It is desirable, from time to time, to take counsel with ourselves and examine the appropriateness of our activities. In such a stock-taking there are three simple practical criteria which are sound and which any health officer can use in determining where to direct his major efforts.

The first is that of disease prevalence. What are the biggest community health problems as indicated by morbidity and mortality rates and other statistics? If there were no other factors to be considered, these figures would at once clearly determine our attack. However, important as these figures are, this criterion cannot be used alone because we do not have any known means of effective attack on some of these rates.

The second, therefore, is, What are the known effective procedures? If this criterion alone were rigidly applied, our program would be quite elemental because there are, in fact, only a few procedures which are infallible: vaccination, inoculation against diphtheria and typhoid, pasteurization, water purification and a few others.

* Presented at the 11th Annual Meeting of the Pennsylvania Public Health Association, Harrisburg, Pa., May 21, 1935.

In addition to these two scientific criteria, there is a third practical consideration which the professional man is frequently apt to minimize. That is public opinion. Since we derive our support from public funds, we must do some of those things which the people who support us think we should do. Only in this way can we get continued support to do the things we want to do, pending that happy time when, through sufficient public education, the things we want to do and the things the public want us to do become identical.

THE CRITERION OF STATISTICS

Applying the first of these criteria to our local public health picture, we find a large group of diseases high in the list of causes of death, disease, and disability. They are the so-called respiratory diseases—pneumonia, influenza, scarlet fever, measles, tuberculosis, and others. Most workers believe that all of these diseases are communicable; yet nothing done so far has had any considerable effect in preventing their communication. We believe that all of these enter the body through the mouth; yet we have, in our public health procedures, constructed almost no barriers on this route of infection. We believe that most of them are principally infectious in their early stages; yet we are surprised that quarantine and other post-symptom measures have so little effect. Practically we have, as administrators, accepted defeat in the control of respiratory disease and are awaiting the discovery of some new vaccine, or other sure and easy process of creating an immune population that we will not have to bother about. While thus waiting for the laboratory to produce a solution, people are dying and morbidity rates do not decrease. According to the criterion of statistics, major efforts of the health department should be directed to control of respira-

tory diseases. I need not call your attention to the fact that the full picture of human disability is not given in the morbidity rates for these diseases. They may frequently be the initial factor in contributing to premature death in the later years of the individuals affected. A possibility of conquering just one of these diseases, as we have conquered yellow fever, cholera, typhoid fever, and diphtheria, is a great opportunity. Any possibility of controlling all of them is worth serious consideration.

WAITING ON THE LABORATORY

This brings us to a consideration of the second criterion—What can we do about control of respiratory disease? The defeatist attitude has not produced the brilliant public health victories of the past, and the continued high prevalence of respiratory diseases must act as a challenge to the present generation. In facing this challenge let us examine our current measures of attempted control. They can be classified under four headings: education, quarantine, medical service, and sanitation.

Programs of health education have been specifically aimed at inducing people to build their general health so that they may more successfully resist infection; to secure prompt medical attention; and to avoid infecting themselves and others. In view of the tremendous task to be done—the overcoming of prejudice, inertia and ignorance—changing habits of thought and actions of 120,000,000 people—the public health education program in this country has been puerilely weak. This is not in criticism of all those who with and without training for the task have worked sincerely in this field without much encouragement or anything like adequate support from appropriating bodies. To be thoroughly effective health education programs would require budgets resembling those of

national commercial advertising campaigns. Until funds for public health education have increased many-fold and our technics have become more certain, progress by the educational route will be slow.

Control through quarantine and isolation has been disappointing and some will say that these measures as ordinarily practised are practically without effect in preventing the spread of respiratory diseases. Most of these diseases are infectious in their incipient stages; many occur in mild form and are never diagnosed or reported; carriers play a part in the dissemination of some of them. Quarantine and isolation of the cases actually diagnosed and reported therefore segregate only a part of the potentially infectious population and this part temporarily, too late, and usually incompletely. Quarantine as a standard procedure in some of these diseases has already become less severe; at best it is an inadequate measure of control.

Medical treatment and nursing care of diagnosed cases are not to be omitted in listing measure of control, particularly as these services reduce the infectiousness of the attacked individual. They also may have a material effect in reducing the incidence or seriousness of after effects, postpone death, and thus are quite definitely public health measures with a bearing on the death rate. Good medical service and nursing care are essential in the public health control of any disease. They do not in themselves furnish a program.

Of the four measures of control then there are education which is weak, quarantine which is uncertain, medical service which is insufficient, leaving sanitation to be considered. The control of respiratory disease through sanitary measures has seldom been tried thoroughly in a sustained program. While waiting for the laboratory to discover a readier measure of control,

this may offer a fruitful means of attack. Sanitation as here considered means the establishment of procedures wherever possible to prevent the mouth discharges of infectious persons from being imbibed by others.

The only important point at which the health officer has it in his power to interpose barriers to this salivary exchange is in his supervision of public places serving food and drink. Furthermore, he is the only person who can erect and maintain this barrier. Among all of our public health programs sanitation of the public germ exchange as it exists today is one of the most difficult. The problem is complicated by lack of inspectors, uncertainty of procedures, the tremendous increase of public eating places, particularly of the rush order or counter type, and the hostility of food and drink dispensers to any program that requires them to spend money.

A recent and serious factor is the return of the saloon, or as we politely call it, the tavern. In prohibition days we could ignore speak-easies because they were supposed not to exist, and without legal existence we could not enforce public health ordinances to protect their customers. Now that the bar has moved from the basement to the first floor, or from the back room to the front room, we are necessarily faced with a sudden increase in our problem of sanitary supervision. There is a tradition among bar tenders that beer glasses should not be washed. This is fostered by the brewers. It has caused a falling off in the standards for all glass washing, according to the Los Angeles City Health Department.¹ With beer dispensing leading the downhill parade, vigorous action by health officers is called for if the gains which have been made are to be preserved. Already Vincent's angina is on the increase, and many communities have reported epidemics of this disease.

The U. S. Public Health Service,² the American Medical Association,³ and countless health authorities have reiterated that the commonly used unwashed drinking glass or other drinking or eating utensils may transmit infections; yet by and large, we have really done very little to eliminate the common drinking cup as it is seen at soda fountains, roadside stands, and quick lunch counters. A dip and splash in a tank of dirty water does not sterilize, yet this is about all the washing that most of our eating and drinking utensils get in many public places serving food and drink today. If we do not take this situation seriously, we cannot expect the public or the dispenser to.

Here is a statement from a news release of the health department of a large city:

At the larger resorts two men are on duty night and day and they see to it that hamburger and hot dogs stand keep meats and breads from possible contamination. Glass washing and the scalding of all dishes and cutlery is closely watched by these inspectors.

Such a statement is an insult to the intelligence of the thousands of people who patronize these stands and whose eyes tell them that glasses are not washed and dishes and cutlery are not scalded. But when an able and distinguished health officer makes a solemn statement of this nature and a child can see that the situation is otherwise, he invites the purveyor's disrespect of the law and dulls the sanitary sensibilities of the public.

There is no insuperable impediment to the sterilization of public eating and drinking utensils. The problem has been partly met in some places by the use of individual cups made of paper which are used once and thrown away. But where individual service of this kind is not desired there are available dishwashing machines of all sizes which effectively cleanse and sterilize. If this

equipment cannot be afforded there are inexpensive means of sterilizing by hot water, steam, or chemicals.

The importance of sterilization of commonly used eating and drinking utensils has been shown by many investigators. The studies by Cumming,^{4,5} and by Lynch and Cumming⁶ on the transmission of influenza are particularly thorough and significant. Nevertheless there is still a great need for continued research in this field. Many questions need further exploration such as:

1. What temperature of wash waters and exposure times are necessary to secure adequate bacterial destruction?
2. What criterion can be established for determining when cleansing is "adequate"?
3. What is the relative effectiveness under operating conditions of chemical sterilization versus heat sterilization?
4. Is there a test organism that can be used to measure pollution from respiratory sources as *B. coli* is used to measure pollution from intestinal sources?

In addition there is need for a simple standard method of laboratory examination by which the health officer can determine whether or not a dispenser of food and drink is obeying laws and ordinances. An inspection of the premises will not suffice. A standard method of examination of wash water or of dishes which could be used as a routine such as we have for the examination of water and sewage and milk would be most helpful in enforcement and would aid materially in comparing the results by various investigators in this field. Other more extensive studies, particularly in the realm of epidemiology, offer prospects of interesting and important results. These are problems which are particularly appropriate for the State Health Department and the universities of this state working in coöperation with local health officers.

Another phase of the program in which the state or national health au-

thorities may well take the leadership in the development of model laws and ordinances. Present regulations concerning the sanitary care of eating and drinking utensils are frequently ambiguous, sometimes impracticable, and in a few jurisdictions nonexistent. The present legal situation is analogous to that which existed in the field of milk sanitation before the adoption and promulgation of the model milk code by the U. S. Public Health Service. State and national leadership in the preparation of model laws will follow if local health officers demand it.

In the meantime much can be done under existing rules. The immediate arm of the health officer in this job is the inspector. With the limited inspection service which most health departments have there is all the more need for focusing this service on the most important tasks. Too often the inspector spends most of his time in observing and reporting on cleanliness of walls and floors and ceilings, whereas the habits of employees and the thoroughness of dishwashing have a more direct relationship to the prevention of disease. Many inspectors enter their jobs with but little training. The only training they get usually is a few days' observation of how the other inspectors handle their work. Thus the errors and deficiencies of the inspection service are carried on from one generation of inspectors to another. These men are important links in the chain of public health protection. A specific course of training for them would be a valuable aid. One city health department (Detroit) goes beyond this and has a program of instruction for the food handlers themselves. The universal adoption of this plan is worth consideration. The present offers a unique opportunity for concentrating on this task through the use of relief workers. The city of Chicago has recently added 200 inspectors to its staff

by this method. The use of more inspectors well trained for their jobs and focusing their efforts specifically on points of danger offers health officers another possible means of controlling respiratory diseases. To reach this objective requires more than a mere overhauling of the inspection service—it requires a completely new approach which will recognize the dignity of the task.

Finally there is a fourth weapon which can be used with little expense, namely, publicity. This was a powerful weapon in improving the milk supply and can be used with equal or greater effect in this field. Most of the things a health officer does are unobserved by the public. They can see no tangible evidence of his activity. The sanitary condition of public eating and drinking places is a matter of almost daily concern to a large number of the health officer's public. This latent interest can be mobilized behind the health officer. It is a force that can be brought to bear with particular strength—for dispensers of food and drink who obey the law, and against those who wilfully and repeatedly violate it. There are few communities in which the citizens would not welcome an opportunity to aid the health officer in a problem of public housekeeping such as this—one which exposes them to unpleasant conditions and potential dangers. Indeed, the health officer who takes the opportunity for leadership of this kind will win for himself a measure of esteem and approbation which should carry over for his whole program.

This brings us back to the third criterion for determining a program—public opinion. There is an unmistakable tide in modern America toward a higher standard of living, toward cleanliness and away from dirtiness. The situation which exists in public eating and drinking places, particularly soda fountains and other counter service

places, is an anachronism. It is on a par with the common drinking cup in railroad cars, and spittoons in the office. The people sense this but, not knowing how to change it, they accept it as the older generation accepted the open privy, and make jokes about it. At one eastern university when a couple of students go across the street for a milk shake or a "dope" they say "let's go over and swap spit." The health officer can capitalize on this latent public feeling and build good will for himself, his department, and his city administration. There is reasonable evidence to indicate that it offers an opportunity for the control of respiratory disease.

Hermann M. Biggs Memorial Lecture

BIGGS had an orderly and logical mind. These qualities tempered his idealism and his professional vision. "Think things through" was his motto. No one before or since his time has combined with such idealism so practical a program for meeting the public

health and medical needs of his state. Had his program of 1920 been adopted in New York State and carried out in the several communities, we should have today no such serious problems in medical care and medical economics as now confront us.—Thomas Parran, Jr.

THE PASTEURIZATION OF CERTIFIED MILK

AN important and far-reaching event in the progress of certified milk, and of milk sanitation generally, was the approval given to permissive pasteurization by the American Association of Medical Milk Commissions at their annual meeting in Atlantic City, N. J., in June, 1935. Following a remarkable program of papers devoted to this topic, the Association voted unanimously to include in its Methods and Standards, definitions and specifications for Certified Milk—Pasteurized, an action which will be received with acclaim by all health officials.

For more than 40 years certified milk has been recognized as a superior grade of market milk. It was developed as a quality milk supply in which physicians, sanitarians, and the public might have confidence, and it has always been produced by leaders in the dairy industry in accordance with uniform, national standards. These exceptionally high standards have been enforced not only by health authorities but by impartial medical milk commissions representing local medical associations. Today there are 81 such commissions in some 25 states.

Despite the high quality and excellent sanitary record of certified milk, and despite the somewhat limited sale of this necessarily more expensive product, many health officials have felt that pasteurization of it would be desirable and logical, since this process would add the final factor of safety to a clean milk of unusual quality. Numerous scientific investigations have shown that pasteurization would in no way impair the excellent nutritional qualities of certified milk.

The unmistakable trend toward pasteurization was recognized several years ago when the certified milk sold in Boston was subjected to this beneficial process. Today, the demand for pasteurized certified milk in this city exceeds that for the unpasteurized, an experience which has also been duplicated in a number of other communities where certified milk—pasteurized has been introduced in recent years.

Until last June these certified milks—pasteurized had not been sanctioned by the American Association of Medical Milk Commissions, and considerable opposition had been registered when the use of this process for certified milks was first proposed some 5 years ago. The present decision is, therefore, all the more

gratifying in revealing a spirit of progress, and of coöperation with health officials who have been advocates of the more general pasteurization of all market milks.

Since this wise procedure also has been endorsed by the Certified Milk Producers' Association of America, a substantial increase in the distribution of certified milk—pasteurized may be expected in the future. That the more extensive adoption of the process will result in greater public appreciation of this superior milk seems likely, especially if there is created a new national organization for the purpose of promoting greater consumption of certified milk, as was proposed by one of the speakers at the Atlantic City meeting.

It was pointed out at that time, and we agree, that the action taken in favor of permissive pasteurization was a landmark in the development of certified milk, an episode which is as significant to dairy science and to public health as was the institution of certified milk itself in 1893. Physicians and consumers who desire a clean and safe raw milk can still obtain it, but an even greater proportion of discriminating physicians and consumers who prefer that the best milk obtainable be pasteurized will at last be satisfied. Health officials will now have added reasons for recommending and advocating increased consumption of these certified milks.

"HEALTH TODAY AND TOMORROW"

UNDER the above slogan, a campaign has been opened by the National Health Council, with special reference to the local campaigns of various organizations related to the health movement in the United States.

During a 5 months nation-wide campaign, the Council will seek to dramatize its various objectives. A program of surveys of community health agencies will culminate in October on a date to be chosen by each community around October 21. On that date it is proposed that an open town meeting will be held after the pattern of the New England town meeting. At that time local people will ask leading questions regarding the health agencies and social services available in that community. Questions will be asked whether they are well managed and how adequate the plans and appropriations are for the purposes of that particular community.

This campaign is to be specially promoted in about 400 cities of the United States where both the official and voluntary health and social work organizations have promised strong coöperation.

The American Public Health Association is one of the 17 participating agencies in the National Health Council. Although this plan is aimed more directly toward the promotion of interests of various "operating agencies," this professional society of public health workers has taken the position that there are wide possibilities of usefulness in this campaign. It is also our opinion that the guidance of such town meetings as those planned in October is so important as to demand the informed participation of those qualified to lead in the public health field. Wherever it can succeed in stimulating public interest and extending public information this campaign can materially benefit health department personnel in their relationships with the public and there can be provided excellent background material for campaigns to expand the budgets of health departments.

The *Chairman* of the Committee for this campaign is Louis I. Dublin, Ph.D., who is working with the President of the National Health Council, Colonel Theodore Roosevelt. Information and assistance in this campaign may be secured by addressing the Publicity Director, Margery Currey at the National Health Council, 50 West 50th Street, New York, N. Y.

THE COPELAND BILL

THIS Association, at the Indianapolis meeting in October, 1933, recorded, by resolution, the confidence of its members in the principles and purposes of the Federal Food and Drugs Bill then pending in Congress.

In the year and more since that action, much has happened in Congress. The original Copeland measure died with adjournment in 1934. The new Congress received a new Copeland Bill, which passed the Senate in May, 1935, and is, at this writing, before the Committee on Interstate and Foreign Commerce of the House. Various observers are of the opinion that the Bill will receive early consideration by that committee and that a strengthened Federal Food and Drugs Law will probably be enacted at this session of Congress.

The need of a new food and drug law was emphasized by President Roosevelt, in a message to Congress, a few months ago. "A measure is needed," he said, "which will extend the controls, formerly applicable only to labels, to advertising also; which will extend protection to the trade in cosmetics; which will provide for a coöperative method of setting standards and for a system of inspection and enforcement, to reassure consumers grown hesitant and doubtful; and which will provide for a necessary flexibility in administration, as products and conditions change." In concluding his message, the President said:

The great majority of those engaged in the trade in food and drugs do not need regulation. They observe the spirit as well as the letter of existing law. Present legislation ought to be directed, primarily, toward a small minority of invaders and chiselers. At the same time, even-handed regulation will not only outlaw the bad practices of the few, but will also protect the many from unscrupulous competition. It will, besides, provide a bulwark of consumer confidence throughout the business world.

It is my hope that such legislation may be enacted at this session of the Congress.

The Copeland Bill, as passed by the Senate in May, will give to consumers new and additional protection, such as is not possible under the present law.

It prohibits false advertising of foods, drugs, and cosmetics.

It regulates the sale of cosmetics, requiring truthfulness in labeling and outlawing those injurious to health.

It prohibits, to a greater extent and under closer control than under existing laws, traffic in foods which are dangerous to health.

It bans the use of poisonous containers for food.

It requires adequate sanitation of establishments handling and manufacturing foods, drugs, and cosmetics.

It proscribes deceptive and slack-filled packages of foods and drugs.

It brings devices used as curative or preventive agents under the same regulation as drugs.

It provides for the regulation, for the protection of the consumer, of dangerous drugs and drugs subject to deterioration.

It makes provision for a Committee on Public Health to aid and advise the Secretary of Agriculture in promulgating regulation for the protection of the health of the public. It also provides for a Committee on Food Standards.

These committees, advisory in nature, are to be appointed by the President. The Public Health Committee is to consist of 5 members, designated without regard to political affiliation and with a view solely to scientific attainment and interest in public health, as it relates to foods, drugs, or cosmetics. The Committee on Food Standards is to have a membership of 7—3 representing the public, 2 representing the food industry, and 2 from the Food and Drugs Administration.

Members of the Public Health Committee and those members of the Food Standards Committee who represent the public are all prohibited from having any financial interest in the food, drugs, or cosmetics industry.

It is to be hoped that, when and if the Copeland Bill (S5) is passed by the House, it will be so amended as to permit the seizure, without restrictions, of shipments of drugs, foods, or cosmetics which are so misbranded as to be grossly deceptive.

The bill, as passed by the Senate, provides that only one seizure may be made of an alleged misbranded product, unless the enforcing officials can prove that the product is so misbranded as to render it imminently dangerous to health, or such misbranding has been the basis of a prior judgment in favor of the United States. This provision greatly limits the protective effects of the pending law in preventing the removal from the market of grossly misbranded products, which may not in themselves be "imminently" dangerous to the health of the consumer, but which would be valueless in the conditions indicated by the labeling.

The Copeland Bill (S5), as passed by the Senate and now before the House, will, if enacted into law, give to the consumer much needed added protection. Its principles and intent are the same as those contemplated by the first Copeland Bill, introduced in Congress in 1933, and approved by this Association in the resolution before mentioned. The reasons which influenced the Association in soliciting, in that resolution, the support of all members in behalf of the first Copeland Bill, apply with even greater force in the case of the Copeland Bill now pending.

MEDICAL HISTORY IN THE UNITED STATES

IT seems fair to credit the late Sir William Osler with having awakened interest in medical history in the United States. He was constantly looking up some great man of the past who had done big things in this country, though practically unknown to the present generation. Many arguments can be brought forward for the study of history. Dr. Osler said, ". . . I hold strongly with the statement that it is a sign of a dry age when the great men of the past are held in light esteem."

Another wise man who helped a great deal was the late Dr. Victor C. Vaughan. He told us that when cerebrospinal meningitis appeared in the United States it took us many months to learn facts about the epidemiology of the disease which had been demonstrated conclusively by French Army surgeons in the first half of the 19th century, the reason being that we did not know French history. He also pointed out that no one could claim to be learned in any specialty until he was fairly familiar with what had been done previously along the same line. This is an obvious fact, and yet too many in the medical profession fail to recognize it.

These statements are given point at the present moment when we learn that the *Annals of Medical History* is in danger of being discontinued, because, though it has many readers, it has few subscribers. It was founded under the editorship of Dr. Francis R. Packard, in 1917, and each number has been filled with interesting histories and reviews of literature. It is beautifully printed and is an ornament to any library. It would be a distinct loss if it had to be discontinued for any reason.

All of us can recall the desperate struggle which was carried on to keep alive

the *Index Medicus*, which was finally accomplished by merging it with the *Quarterly Cumulative Index of Current Medical Literature*, now published by the A. M. A., yet the medical profession would be handicapped without this publication.

The *Annals of Medical History* is necessary to us in this country, and we trust that interest enough can be aroused to secure sufficient subscribers to keep it going. This is another effort which might well be supported by some philanthropist, but it lacks the spectacular features which often carry a strong appeal.

America, though a new country, has produced many notable physicians and surgeons, who under the most trying circumstances and with meager facilities, have done great deeds for the advancement of their profession. Some of these men had European training and contacts with the older countries, but some of the most notable were pioneers in the truest sense, to whom God had given brains, resolution, and resourcefulness. While here and there the stories of different men are told, the *Annals of Medical History* is the only journal in the country which makes a business of collecting the histories of medical men and medical events. It could ill be spared.

PUBLIC HEALTH EDUCATION*

What Would You Like to See?—What kinds of materials, and what topics would you like to see at Health Education Headquarters at Milwaukee in October?

The editor of this department would like to hear from you.

The 1935 Health Education Institute—Elsewhere full details are published concerning the fourth institute conducted by the Public Health Education Section.

Those who enroll for the Institute in Milwaukee should bear in mind that *this year attention will be given to the problems of smaller cities and rural communities*. Those who come from larger places should not be disappointed and should not try to distract attention by any reference to their particular needs.

The Hall of Man in Buffalo—Buffalo may well become a Mecca for believers in the value of three-dimension displays in health education.

The Hall of Man, Buffalo Museum of Science, probably contains the largest collection of three-dimension health exhibits now available in this country.

A 20-page illustrated "Guide" is obtainable by sending 15 cents to the Museum.

The Microphone in Health Education—"Social Work at the Microphone" takes only a few of its examples from the health field, but as a whole this practical discussion applies to health education broadcasting.

The contents includes: five principles of broadcasting, types of programs, production, listening, and listening groups.

The reading list is limited to references carefully selected from a number of titles for helpfulness to educational broadcasters in the health and social work field. Health education provides two of the most useful titles under "Radio Techniques," and health sources are named under "Collections of Talks or Plays."

Issued by Social Work Publicity Council, 130 East 22d St., New York, N. Y. 17 mimeographed pages. 40 cents.

Town Meetings on Health—Elsewhere you have learned of the "Town Meeting" campaign sponsored by the national agencies represented in the National Health Council.

Diverse national and local activities will culminate in numerous "old fashioned New England town meetings" for the consideration of personal and community health.

Actively in charge are Margery Currey and Ralph M. Prouty, to be addressed at National Health Council, 50 W. 50th St., New York, N. Y.

Eager to Learn on the Job—One hundred and ten registered for the first Post-Graduate Study Course on Health Education, sponsored by the Committee on Health Education of the Conference of Tuberculosis Secretaries, and held preceding the recent annual meeting of the National Tuberculosis Association.

This record, and the equally too large attendance at the several Health Education Institutes in connection with

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

A.P.H.A. annual meetings, suggest that something should be done about it.

Some questions that seem to call for careful consideration:

1. What kinds of workers respond to these opportunities—classified as to job, experience, training, etc.?

2. What do they *think* that they need, and what do they actually *need*—as suggested by classification mentioned above?

3. What kind of a program should be planned, as well as the subject matter?

4. When and where could additional institutes be held to increase the total number of participants, and to reduce to manageable teaching numbers those present at each institute?

5. Could satisfactory programs be provided, and would there be a satisfactory registration for regional, or even state institutes?

6. Under what auspices could these more numerous institutes be held?

Probably such questions as the above should be considered even before taking up the details of number of sessions, fees, number of registrants to be accepted, how to screen the applicants to the best advantage of all concerned, and so on.

We hope that the Conference of Tuberculosis Secretaries, the Public Health Education Section, and the Committee on Professional Education of the A.P.H.A. will all participate in this important task of exploration.

"Syphilis—Press and Radio"—

Under this title a special collection of material which has been printed or spoken will be displayed at Milwaukee in October.

Original clippings or copies of editorials and news stories, and copies of radio talks will be displayed.

We hope to receive copies of material which has been suppressed.

"I Will Drive Safely"—This slogan and pledge is offered by *Ladies' Home Journal*, Philadelphia. It is supported by a series of articles and editorials: In the June, 1935, issue

Paul de Kruif argued that "Accidents Don't Happen." In July a page editorial submitted to its readers an emblem bearing the slogan, the emblem to be displayed on the rear of the car "as a token of your intention to drive carefully."

Write to Philadelphia for copies of the material issued by the *Ladies' Home Journal*.

The Summer Round-Up of Children—A total of 2,580 communities registered for the Summer Round-Up of Children, a project sponsored by the National Congress of Parents and Teachers, 1201 16th St., N.W., Washington, D. C.

Of those registering 1,417 communities were represented by units which carried through the plan. Children receiving the Round-Up examination numbered 92,268; 34,113 were vaccinated against smallpox; 27,101 received immunization against diphtheria in 1934.

Health workers may wish to ask for the 1934 report, and the detailed plan and work material for 1935.

Much remains to be done to carry to completion the 1935 Round-Up. Health authorities may readily locate the local units, if contacts have not been made already.

Again That Annual Report—In "Why Write or Print an Annual Report?" Dr. W. Frank Walker answers a group of questions which must be faced some time during the year:

Shall I write an annual report? Why should I? What is to be gained by it? What should be the form? What shall I put in it?

The whole article is something to be read when those questions came up.

In conclusion Dr. Walker says:

In deciding whether any detailed material should be included in the tabulation of service, the director should have clearly in mind

the purpose and advantage of including the material. Unless the figures go to support or illuminate the text already discussed or provide the reader with a background of detail which may be helpful to him later in deciding questions of policy, there is little point in including them. The mere fact that figures relating to the service have been collected over the year and the tabulation is available is no justification for taking the space in an annual report to present them, or the reader's time to consider them. When one considers the annual report as an opportunity to review critically the work of the organization, to present its services and problems to the executive board or to the public in a way in which they can be most readily understood, then one should have little difficulty in deciding what should be presented or, within certain limits, the most effective way of its presentation.

Supplementary to the above is "Monthly and Annual Reports," by A. J. Miller, with direct application to data collected by public health nursing groups.

Both articles in *Public Health Nursing*, 50 W. 50th St., New York, N. Y. June, 1935. 35 cents.

We Are Not Discouraged—In "Progress and Trends in Public Health in North America," Surgeon General Cumming, U. S. Public Health Service, gives background material of considerable value.

Speaking of health education Dr. Cumming said:

While we have often been discouraged by the apparently slow progress in educating our public in matters of public health, there nevertheless has been a dissemination of knowledge that even in the traditional field of public health endeavor little progress has been made against venereal diseases, that our infant mortality rate should be halved, that our maternal death rate is disconcertingly high, that because of our lowering birth rate and lengthened longevity we are an aging population, and that the problems of adult health are increasing in importance. The field of public health is broadened, the emphasis is shifting from accomplished environmental sanitation to personal hygiene and care. The people are aware of the great

store of medical knowledge and the benefits which would follow if they were available for all. It is common knowledge that despite the self-abnegation, altruism, and devotion of our profession a large proportion of our peoples do not, and cannot, under our traditional relationships of doctors and public receive the benefits of this knowledge. The economic depression with its consequent necessity for governmental aid in relief along other lines has focused attention upon this defect in our social relationships.

Given before a joint session of Canadian health bodies. In *Canadian Public Health Journal*, 105 Bond St., Toronto 2, Ontario. June, 1935. 35 cents.

"Are People Interested in Health?"—This question put editorially by "P.P.J." is answered in part by this statement:

Some idea of interest in public health may be obtained from the fact that within the last ten years one large publishing house has distributed 700,000 copies of the National Health Series, the 24 little books on health prepared by the National Health Council.

In *Journal of Outdoor Life*, 50 W. 50th St., New York, N. Y. June, 1935. 15 cents.

Health Education in June, 1935, Journal—*The American Journal of Public Health* carried references to health education in the June, 1934, issue.

In "Serving the Public for Health," by Vaughan (pages 681-686), are numerous references to health education including mention of:

. . . a whole-time health service with a full-time health officer assisted by adequately trained health educators . . .

In "Serving the Public for Health," by Pomeroy (pages 687, 694):

Public health education itself has distinct and specific limitations. The most successful campaigns of health education, in my opinion, rest partly upon individual health service.

In Dr. Pomeroy's summary:

3. Health education must include at pres-

ent both mass and personal instruction. In competition with cultism and quackery, demonstration and individual services are necessary to win many people back to scientific medicine.

See the whole of "Selling Health Department Members First on Health Education," by Williams (pages 715-719).

Also to be read in full is "The Community Program of Health Education," by Turner (pages 725-729).

Under "Toward the Solution of Social Medical Problems" (page 772), is mention of "an excellent distinction between health education and propaganda."

"What's a Committee?" quoted on page 740, reflects many a committee with a poor chairman, but its picture of "the ideal committee" is the expression of an ineffective chairman.

Massachusetts Wants to Know— And so do other states and cities want to know where to get health posters for school use.

A partial answer is supplied by "Some Posters on Child Health," an 8 page folder from American Child Health Association, 50 W. 50th St., New York, N. Y.

Here is the original request from Frank Kiernan, Massachusetts Tuberculosis League, Little Bldg., Boston:

There is a demand in Massachusetts for health posters for elementary and secondary schools. The orange and black posters of Gerta Ries which have been popular for several years seem to have outlived their usefulness. Do you know of anyone in the country who has done anything notable during the past year along this line?

The "Conspiracy of Silence" Is Breaking— Additional reports in this issue encourage the belief that both radio and journalism will give up their hypocritical silence on the venereal diseases.

We hope for additional reports.

We hope also that newspaper clip-

pings and letters will be sent to the two major broadcasting chains, addressing them at New York City.

Most people who write to newspapers and to broadcasting stations object to something. Hence it seems worth while also for health workers to encourage parents and others to thank their editors and their broadcasters when they talk normally and directly about syphilis, or when they permit others to do so.

Journal of Outdoor Life Passes— The *Journal of the Outdoor Life* will be discontinued in December, 1935.

Founded in 1904, and since 1910 published by the National Tuberculosis Association, this magazine was issued as an educational project, addressed primarily to tuberculosis patients.

The Board of Directors, at a recent meeting, decided upon the discontinuance, for reasons which have been summarized as follows:

(1) The diminishing number of tuberculosis patients who read the magazine; (2) Because of changes in opinion on the part of physicians, both in sanatoria, and in private practice relative to its value as a patients' magazine.

It is to be hoped that some medium will be found to carry on some of the *Journal* features.

MAGAZINE ARTICLES

"Atlanta Thyroid Clinic," by A. L. Whatley. *Junior League Magazine*, 305 Park Ave., New York, N. Y. July, 1935. This is a sample of reports in the magazine on local health activities of Junior Leagues.

"Birth Control before the Medicos." Report of decision of House of Delegates at Atlantic City to appoint a committee to report next year on the legal and medical aspects of birth control. *Literary Digest*, 354 4th Ave., New York, N. Y. June 22, 1935. 10 cents.

"Doctors, Patients, and the State," by John A. Hartwell, M.D., former

director of surgery at Bellevue Hospital, and chairman of Medical Advisory Committee, Emergency Relief Bureau. "To call attention to the fact that a problem in medical practice does exist and that socio-political forces are demanding its solution." *Harper's Magazine*, 49 E. 33d St., New York, N. Y. July, 1935. 40 cents.

"Great Falls, Montana, Works on Anti-Tuberculosis Campaign," by R. B. Caples. What the local Kiwanis did, largely in coöperation with the City-County Health Department. *Kiwanis Magazine*, 520 N. Michigan Ave., Chicago, Ill. June, 1935. 15 cents.

"Medical Magic," by David Dietz, science editor of Scripps-Howard. A series of feature articles on the scientific marvels behind disease and health.

"The Plight of Our Hospitals." Editorial on "a serious matter of public safety." *Saturday Evening Post*. March 16, 1935.

DATES AHEAD

Now is the time to gather photographs and movie pictures of outdoor activities in which health agencies are interested, or which they wish to further next winter.

All too often there is delay in getting satisfactory pictures from camps, sanatoria, bathing beaches, swimming, first aid, and so on.

Prints of news photographs, whether or not they are used in the papers, may prove useful in getting out printed matter.

Good amateur photographers or movie operators may well be cultivated at this season.

Careful search of the past may reveal an anniversary of some type which might be celebrated in the fall or winter, or at least could be used to advantage in a news story. One may rediscover a pioneer in health, a professional worker, or a prominent layman. The first printed report; the first educational leaflet; the first vital statistics for your community; or a "first" of some kind or other which could be used to advantage.

Note August topics which might be played up a year from now.

September is "Safety Highway Month." Write National Safety Council, 9 East 41st St., New York, N. Y., for information to be checked to see if you can do anything about it.

Does *Labor Day* have a health significance? Does it offer a chance to "point with pride" to better health conditions in and out of work places to which health agencies have contributed?

As school opens have we summer credits and fall obligations to discuss toward the better health of school children?

The annual meeting of the A.P.H.A. in October gives news value to many topics. Advance planning as to topics locally significant, and how to make use of the material presented at Milwaukee, should be resultful in your city or state.

Reorganization of the Federal Vital Statistics Division

AS Director of the Census, I am adopting this method of announcing a reorganization of the Division of Vital Statistics of the Bureau of the Census to those who are professionally interested. For approximately one-third of a century the fundamental task of the Bureau in this field was to extend the registration areas for births and deaths. With the admission of Texas to both areas in 1933, this primary responsibility was ended. The period since that time has been one of transition, in which we have sought to appraise and prepare for the new types of work for which we must now become responsible. We have realized that new tasks must be undertaken while past gains were preserved and consolidated.

In 1933, the Joint Advisory Committee of the Director of the Census took steps to explore the various questions and problems involved. Its inquiry resulted in a report to the Director on January 17, 1935. This report calls attention to the great opportunity for the development of vital statistics in this country. It asserts:

Country-wide registration furnishes comprehensive data for the first time. While it is still necessary to work for more complete and accurate recording of the facts as to births and deaths, new and intensive effort can be devoted now to analytical treatment of the data and to the presentation of more refined results. A better statistical basis for public health work will be laid, and for all studies of population structure and changes.

The United States is in about the same situation as England was in the last century when William Farr began his studies and publications, which placed his country in the position of unchallenged leadership in the public health movement.

Continuing, the report points to a num-

ber of specific "problems in vital statistics which press for solution," analyzes the qualifications of the personnel which should be entrusted with these problems, and concludes with detailed recommendations to the Director.

This report and its recommendations have been approved by the Director and the Secretary of Commerce. The reorganization now under way is the result. It is our immediate purpose to place new supervisory personnel in charge of each of three important types of functions within the Division.

Heading the Division as Chief Statistician will be Halbert L. Dunn, M.D. (University of Minn.), Ph.D. (Minnesota, in anatomy), Director of the University of Minnesota Hospitals, and Professor of Medical Statistics in the University of Minnesota Medical School. Dr. Dunn was a former director of the statistical work of the Mayo Clinic at Rochester. In addition to his general supervisory responsibilities, Dr. Dunn will have direct charge of the development of the research and analytic developments for which the report of the Advisory Committee calls. He will assume office on or before July 12, 1935.

As Assistant Chief Statistician of the Division, the Bureau has appointed John Collinson, M.D., D.P.H. (both Johns Hopkins), who has resigned his positions as Registrar of Vital Statistics for the State of Maryland and Secretary of the American Association of State Registration Executives. Dr. Collinson will be in immediate charge of the development and perfection of registration and of relations with state health officers and registration officials.

The Bureau is now negotiating for

the appointment of a Technical Assistant to the Chief Statistician for Vital Statistics who will have immediate charge of the classification and coding of causes of death, the development of the *Joint Manual*, representation of the Division respecting changes in the *International List*, and relations with medical schools and the medical profession.

The Chief Statistician will be especially assisted in the development of this program by Forrest E. Linder, Ph.D. (University of Iowa), whose scientific training and publications have been in the fields of psychophysics, biometrics, social and abnormal psychology. Dr. Linder resigned a position with the Worcester (Mass.) State Hospital to take office in the Bureau on June 1, 1935.

The Division's budget for the coming fiscal year likewise provides for the appointment of 6 field agents who will represent it in maintaining direct contacts with state officials. A districting of the United States for this purpose is contemplated. It is hoped to obtain for these posts, with the coöperation of the Civil Service Commission, well qualified young men of scientific and medical training.

These changes have permitted the assignment of the present Chief Statistician of the Division of Vital Statistics to other important functions within the Bureau of the Census. On or before July 12, 1935, Dr. T. F.

Murphy will become Chief Statistician of the newly established Division of Religious Statistics, General Information and Records. In this position he will be responsible not only for the forthcoming decennial census of religious bodies, but in addition for the development of the Bureau's too-much-neglected services of information to the public, and for its public relations generally. Willard C. Smith has been promoted, at higher grade and salary, to the post of Assistant Chief Statistician of the Division of Population, where he will bear much of the burden of the projected 1935 census of population, unemployment and occupations, and of developing the Bureau's activities in the population field in anticipation of the decennial inquiry of 1940.

The foregoing changes accompany others now taking place or in prospect in various Divisions of the Bureau of the Census. They are motivated by considerations of public service, scientific progress, and merit as a guide to the selection of personnel. It is our ambition to build up the Bureau to a point where it may without challenge be regarded as the best, as it is now the largest, statistical organization in the world. The Bureau will endeavor to merit support for its program, and we eagerly hope that readers of this announcement will continue to favor us with their confidence and coöperation.

W. L. AUSTIN, *Director*

BOOKS AND REPORTS

The Frustration of Science—By seven authors. Foreword by Frederic Soddy, F.R.S. New York: Norton, 1935. 144 pp. Price, \$2.00.

The thesis of this little volume is that the constructive possibilities of science are not being fully utilized, since we have failed to make the most of recent discoveries in many fields; while, on the other hand, the destructive possibilities are developing rapidly. Even medicine does not escape the general charge, and bacteriology, on which so much of modern medicine, surgery, and public health is based, is held as a menace through bacterial warfare, to which a chapter is devoted.

The book is distinctly pessimistic. Every thoughtful man must recognize that it contains a great deal of truth, without going as far in the gloomy outlook as the essays do. As far as medicine goes, it is pointed out that in Great Britain, Canada and the United States, there are adjustments and readjustments of the courses for medical students showing that all is not well with medical education. The reviewer believes that most of this is due to the reaching after higher and better things, rather than because so much is bad. It is perfectly true, as stated, that science and research are largely controlled by politics in spite of the many foundations, but even the best of these must indulge in some "window dressing." For example, in 1931, in Great Britain, not only were the salaries of the staff of the Medical Research Council reduced 10 per cent, but work which might have saved untold lives perished from inanition through the cutting down of funds.

Perhaps the three most injurious

things given as examples are aerial warfare, bacterial warfare, and the "invention" of sterility. The surprising statement is made that science is losing its prestige in Germany, of all places.

The last paragraph in the book holds that there are only two ways to go; the road which we now seem to be following leading to Fascism, with restriction of output, lowering of the standard of life of the working classes, and a renunciation of scientific progress; while the other leads to complete socialism, which will want all the science it can get to produce the greatest possible wealth.

The book consists of 7 chapters or essays, written by as many different men, the whole being edited by Professor Frederick Soddy. The book merits attention by thoughtful people. The reviewer is not competent to express a positive opinion on the matters discussed, but cannot help hoping that the writers are unduly pessimistic. May their warning lead to further study and avoidance of the dangers.

MAZÛCK P. RAVENEL

Communicable Diseases for Nurses—By Albert G. Bower and Edith B. Pilant (3rd ed.). Philadelphia: Saunders, 1935. 420 pp. Price, \$3.00.

This is a revised and greatly improved text which will be equally useful to nurses working in general hospitals and those employed in hospitals for communicable diseases—to nurses caring for the sick in homes and to those working in institutions. Emphasis is put in prevention as well as care of communicable disease.

The subject matter is thoroughly up-

to-date and is really interesting. Public health nurses especially will appreciate the inclusion of scabies which was left out of earlier editions. "Athlete's foot" was the only disease we looked for and could not find.

We hope the book will have a wide circulation among graduate nurses although it is designed as a textbook for student nurses.

EVA F. MACDOUGALL.

Heredity and Disease—By *Otto L. Mohr*. New York: Norton, 1934. 253 pp. Price, \$3.50.

This book is an outcome of a series of lectures which the distinguished Swedish geneticist gave at Harvard University in the autumn of 1933. The clarity of exposition and the sanity of the conclusions are such that the book ought to be compulsory reading for any person who is interested professionally in the genetics and constitution of the human being.

The book starts in the conventional way by an exposition of the principles of inheritance along the familiar Mendelian lines and includes a very clear account of the gene theory and the genetic experimentation. It is in the part of the book which goes on from special topics to the bearing of genetics on affairs which gives it its special character and value. Thus, the author considers the common neurologic diseases of familial type, diabetes, allergy, and the occurrence of the lethal genes in man. This term is used to indicate those abnormalities usually classed as monstrosities and abortions. Interesting as these chapters are, there is a very valuable discussion of such topics as the X-ray and mutation in which the author discusses the classic and revolutionary work of Müller showing that mutation rate can be increased by environmental events. His discussion of alcohol as a factor in human life which does not tend to create hereditary dis-

eases of mankind demands the attention of those who glibly assume that alcoholism in an ancestor is a cause of mental disease in a descendant. His discussion of such matters as intermarriage and cross-breeding, degeneration, race-crossing, the blue blood, brings this book from a mere treatise on heredity into an important social document which clears the air of fallacy and misconception.

There has been a prevailing tendency among geneticists of the type called eugenists to build up an aristocratic ideal of life which is entirely unwarranted in so far as biology itself is concerned. That there is an aristocratic basis for human affairs is true, but it does not run parallel to the social structure as it is at present constituted. There is no exclusion of the environment in this book as a genetic factor. There should be none. The scientific day is now past when the student of genetics, in so far as it concerns human affairs, can exclude the environment in any discussion of heredity.

ABRAHAM MYERSON

The Harvey Lectures. Delivered Under the Auspices of the Harvey Society of New York, 1933-34. Series 29. Baltimore: Williams & Wilkins, 1935. 262 pp. Price, \$4.00.

This volume contains as a frontispiece a photograph of the late Dr. Alfred Fabian Hess, President of the Society at the time of his death, followed by an appreciation of him and his work, which alone would make it valuable.

Without disparagement to the volumes which have gone before, we feel that the addresses contained in this series are of unusual interest and value. It would be invidious to pick out certain ones, and at best, a selection of this sort would depend largely on the training and individual taste of the

reviewer, since all of them are by men who are recognized as authorities in their line of work, and concern matters of great scientific interest; some of them of more direct practical interest than others.

The printing and binding of the book are excellent, as are the quite numerous illustrations. MAZŸCK P. RAVENEL

Foods and the Law—*By Alexander P. Blanck, of the New York Bar. New York: Peter Smith, 1935. 246 pp. Price, \$2.50.*

This manual for the business man on the laws of the United States with reference to foods and food products presents a simple and non-technical discussion of the federal requirements regarding foods and their interpretation by the courts. The material is clearly stated and should be understandable by persons desirous of information on this complex subject. About half of the book is devoted to the actual texts of the Food and Drugs Act and the rules and regulations of the Department of Agriculture for its enforcement. There is no index.

This well printed book should be of interest and value to food and drug officials and to health officers concerned with this subject, as well as to manufacturers of food products.

JAMES A. TOBEY

The Administration of Health and Physical Education—*By Jesse F. Williams and Clifford L. Brownell. Philadelphia: Saunders, 1934. 598 pp. Price, \$3.00.*

The authors have succeeded in producing an excellent text in a field that has had little recent textbook emphasis.

While there are chapters on Health Service, Handicapped Children, and Health Instruction, the great bulk of the book is devoted to the sanitation of the school plant, to discussions of organization and administration, and to

the facilities and equipment needed for a modern program of physical education.

The discussion of these facilities covering standards of space, number, sanitation, and supervision of gymnasiums, locker rooms, showers, swimming pools, and play fields is well done. Not for years has this material been gathered and set forth in one work.

Chapters on intramural athletics, measurements in health and physical education, the use of publicity, and on budgeting and finance, round out an excellent text.

The educational theories and ideals are kept well to the forefront. The emphasis on the building of skills and training in sports that have a health and recreational value in later life, in preference to interscholastic team games, presents the best thought of the well trained physical educator and school administrator.

This text should be part of the library, not only of all physical educators, but of school administrators, health officials, and others who may be responsible for the building, sanitation, finance, or administration of physical education plants, or for their management. CHARLES H. KEENE

Elementary Human Anatomy, Based on Laboratory Studies—*By Katharine Sibley. New York: Barnes, 1935. 360 pp. Price, \$4.50.*

This text is written with the special aim of providing the student of physical education with usable material for his professional background. Therefore, although all the anatomical parts and organs of the human body are discussed, special emphasis is put on osteology, syndesmology, myology, and the nervous system.

Special diagrams of movement and for palpation of anatomical parts—particularly of joints and muscles—

supplemented by discussion of the use of human specimens in the laboratory, make this text particularly valuable for the study of kinesiology and for the physical therapist.

The illustrations, numbering 213, are excellent, the parts depicted being profusely labelled.

The discussion of the function of parts, especially of the action of muscles, is peculiarly valuable for the student of physical education.

While there are many anatomies, both unabridged and condensed, this *Elementary Human Anatomy* is a real contribution to the educational aids for the special group for whom it is designed.

CHARLES H. KEENE

Fifty Years in Public Health: A Personal Narrative with Comments—By Sir Arthur Newsholme, K.C.B., M.D., F.R.C.P. Vol. I—The Years Preceding 1909. London: George Allen & Unwin, Ltd., 1935. 415 pp. Price, 15 s. net.

This first volume of Sir Arthur's memoirs published in England covers a period in the history of public health and preventive medicine during which phenomenal progress was made. The reader sees these events through very discerning eyes and he may be reminded as he reads of the observation of Dr. William H. Welch that the best approach to the understanding of any subject is the historical.

Such a personal narrative holds certain advantages for the reader, particularly for those who have learned to admire the stimulating and incisive mental approach which has characterized Sir Arthur's written and spoken words these many years. Any medical man whose life has brought contacts with such outstanding figures as John Simon, Edwin Chadwick, William Farr, and Max von Pettenkofer, will have an interesting story, and these circumstances are all the more significant

when the narrator is one who can appreciate the historical significance of these contributions and relate them closely with present-day affairs. One sees our current efforts in tuberculosis control, for example, in a new light in reading the debate on notification of the disease which occurred in England a full decade before it was an acute problem in America. There are many similar subjects which passed through phases of discussion in England before they came into the foreground here, and one familiar with this progress of thought can sometimes speak prophetically with justifiable confidence.

Such a personal narrative affords the opportunity for the author to relate many circumstances of life in England in the 1860's and 1870's which are of importance to public health, though much more evidently so in the light of such an interpreter. There were cultural and religious habits which bore heavily on hygiene when viewed in the long perspective, and one who understands the educational methods of those days can the more readily appreciate the advantages of our own time.

Chapters devoted to the decline of typhoid fever, to infant and child welfare, to housing and poverty, to the continuing struggle against tuberculosis, to vital statistics, and to public medical service, reflect the various fields of interest in which Sir Arthur has been distinguished. His skillful style serves to bring to the reader the important facts in these matters with a minimum of effort. For background purposes the volume can be highly recommended to students of the public health. How significant and hopeful it would be if all physicians might be aware of the development of their science in England! We might more easily achieve a new degree of social mindedness in things medical.

American readers will look forward eagerly to the coming publication of

the second volume in this series, which will review the experience of the years after 1909, during which the author's services to America were even greater than in the earlier period.

REGINALD M. ATWATER

Drugs Against Men—By *Henry Smith Williams, M.D.* New York: McBride, 1935. 184 pp. Price, \$1.75.

This book by a well known scientist gives a large amount of information on the various drugs which are considered injurious to mankind when taken in excess, and which are not necessary to the well-being of the normal person. Some of them, morphine for example, we recognize as indispensable for medicinal use.

The author considers that as a generation we are weaklings, needing drugs to give us the illusion of stability. The book is written for the large class of individuals who are of such unstable, nervous organization as to lack will power to resist the allurements of drugs, among which he includes caffeine, alcohol, the narcotics, the bromides, chloral, aspirin, veronal, and other such products—all "props" for the unstable nervous system.

There can be little question of the correctness of the statements which he makes, but we believe he has gone to unnecessary length in emphasizing some of them. The advice which he gives for abstention from practically all of these is sound, and we feel that the race would be just as well off if his advice were followed to a considerable extent, though we cannot go as far as calling the person who drinks one cup of coffee per day at breakfast a caffeine addict.

Each chapter ends in a summary which gives conclusions and a preachment, printed in italics. All doctors will agree with the author that the administration of the Narcotic Act should be changed and that medical

men should not be restricted by rules made by laymen and enforced by laymen, who in too many cases are political heelers. The author dwells on what he calls the "Los Angeles Reign of Terror." As he says, "it could have happened nowhere else except in America and would not have been tolerated for an hour in any other country of the world, ancient or modern." He followed the court trials in Los Angeles in person. He gives the facts about what he calls "The Billion Dollar Racket." He tells how the Los Angeles Medical Association in December, 1934, threw down the gage to the organized forces of the "dope" racket, and feels that organized medicine must come to the rescue.

We would like to quote at greater length from this book, which we believe will do good, in spite of the opinion that the author is somewhat extreme in his deductions. MAZYCK P. RAVENEL.

Maternal Mortality in Philadelphia—Report of Committee on Maternal Welfare—*Philadelphia County Medical Society*, 1934. 143 pp. Price, \$1.00.

As in the case of the New York report which appeared in 1933 and was reviewed in these columns, this report from Philadelphia represents a sincere attempt to add something to our knowledge of the causes and prevention of maternal mortality, and to improve conditions in the city in which the study was made. It deals with 717 deaths occurring in Philadelphia in 1931-1933. The death certificates were studied and the information so obtained was supplemented by visits to hospitals and physicians, midwives, and families. The data were reviewed by an Analysis Committee.

Space forbids going into many details of this study; the best one can do is to touch on a few significant points with a recommendation to the

reader to go over the whole valuable report for himself.

At the outset a good impression is created by the report's fair discussion of the maternal mortality rate of the United States as compared with the rates of other countries. Much time and space have been wasted on occasion in trying to compare rates which are not fairly comparable—and in propaganda based on such futile comparisons.

There is an interesting and provocative statement of the criteria used by the committee in determining whether to classify a death as preventable or non-preventable and upon whom to lay the responsibility. They frankly state that they have erred, probably, in placing too many deaths at the door of the physician. If this is so, while the motive was good the result may be unfortunate. There is no dearth now of loose talk in newspapers and magazines, exaggerating the responsibility of the medical profession for the maternal mortality; it would serve no good purpose to add to it.

The Analysis Committee in making up its rates and deciding concerning the preventability of death in a given case frequently changed the diagnosis from that given on the death certificate to one which seemed to them to be more in accordance with the facts. For example, 31 of the cesarean certificates were considered to be incorrect, and 22 of them were changed to septic infection. This sort of post-factum decision probably adds considerably to the accuracy of the whole study in the hands of a conscientious and able committee such as this one, but at the same time has its perils.

One finding of the committee emphasizes what a number of commentators have been insisting for some time, namely, that the importance of septic abortion as a factor in maternal mortality has not yet received sufficiently

widespread recognition. This cause was responsible for more than one-fifth of the deaths in the Philadelphia series. Nearly 63 per cent of these were cases of illegal abortion. It is pointed out that if these could have been eliminated there would have been 14 per cent fewer deaths. It is one thing, however, to recognize this needless waste of life, and quite another to do anything effective about it. Neither public education nor the thunders of the Church affect it greatly, it would seem. And speaking of the Church, the committee regarded as non-preventable deaths those due to refusal of a necessary operation on religious grounds. Such deaths are understandable, but can one call them justly non-preventable.

The committee's "Recommendations and Discussion" at the end of the report are definite and frank. Most of them beyond doubt are sound. Nevertheless, one statement appearing here, and a fundamental one at that, seems to the reviewer not to be based on sufficient evidence. It is: "The responsibility for the high maternal mortality in Philadelphia rests primarily with the medical profession, hence the problem of reducing it belongs to the physicians." Such a statement implies that we now have a clear understanding of all the factors entering into the problem of maternal mortality—in Philadelphia or any other community. This certainly seems not to be the case; and every study made only emphasizes the fact that there must be missing or unappreciated factors. Otherwise, how explain the practically undiminished mortality in the face of increasing improvement in medical, nursing, and hospital care, and in public education. A greater effort to evaluate such things as the racial factor or the more or less intangible effect of modern civilized life on the function of childbearing might furnish a lead. Still another need is more studies of control groups—women

delivered under unfavorable conditions and without adequate prenatal care who do *not* die. It begins to look as if the usual type of statistical study cannot be depended upon to clear up the still elusive puzzle of a relatively stationary maternal mortality.

MERRILL E. CHAMPION

Health Education in Senior High Schools—By Dorothy Ruef. *New York: Teacher's College, 1934.* 106 pp. Price, \$1.50.

After 25 years of the modern trend away from physiology toward education for health, educators are entering on that phase that always appears in any enduring effort—the investigation of procedures and results.

This text is a study of personnel, or-

ganization, activities, relationships, and qualifications of staffs in this field of education in New Jersey. It concludes with a summary and recommendations for: a state program of health education for high schools; definite organization of the program fixing responsibility; better training of the specialists and teachers in health education; state certification not only for teachers, but for physicians, nurses, and dentists, with better training for these and placing them on a full-time basis; and an improvement of relationships—closer help and instruction—between the state department of education and the teachers in the field and a better coördination of the health education program within individual schools.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

A Check on Prevention—Reduction in diphtheria mortality in the large cities seems to be petering out. Only 40 fewer deaths occurred in 1934 than in 1933. New England and the West South Central States gave the best records. Diphtheria still shows itself amenable to control measures.

ANON. Diphtheria Mortality in Large Cities of the United States in 1934. *J.A.M.A.* 104, 24:2182 (June 15), 1935.

Nurse-Midwifery in England—Comments upon a recent report on the midwife situation in England, by Dame Janet Campbell, recommending fewer schools and midwives, better training, and that all midwives have nurse's training as a foundation.

ANON. Maternity Service in England. *Canad. Nurse*, 31, 5:209 (May), 1935.

Another Public Health Yardstick—Although the same number of people died of typhoid fever in 1934 as did in 1933, there are encouraging signs of a basically improved situation. An honor roll of cities with no deaths is published, three of which have had no fatalities for 4 consecutive years. An enviable record.

ANON. Typhoid in the Large Cities of the United States in 1934. *J.A.M.A.* 104, 23:2093 (June 8), 1935.

Convulsions in Infancy—In babies that showed history of convulsions, acute infections were the most common cause, accounting for 30 per cent of the number studied. Pneumonia, acute upper respiratory disorders, and sepsis were the most common offenders of this group. Acute central nervous system diseases followed (meningitis being

largely responsible), then infantile tetany, cerebral deficiency, cerebral birth injury, and acute nutritional disturbances. These groups are further analyzed according to age.

BROWN, J. E. Convulsions in Infancy. *Ohio State M. J.* 41, 6:423 (June), 1935.

Public Health Nursing in the West—Completion of a public health nursing survey in San Francisco by the public health nursing committee of the Health Council of the Community Chest led to the recommendations: (1) that a permanent committee be established within the Health Council to correlate nursing services; and (2) that the committee direct a demonstration in public health nursing under centralized direction in a selected area.

CRAIGHAN, L. A. Survey of Public Health Nursing in San Francisco. *Pacific Coast J. Nurs.* 31, 5:254 (May), 1935.

Laboratory Tests for Syphilis Compared—Serum specimens from a large number of syphilitic patients and non-syphilitics were sent to 13 serologists. The study reveals the relatively equal value of complement fixation and some of the more satisfactory flocculation tests.

CUMMING, H. S., *et al.* The Evaluation of Serodiagnostic Tests for Syphilis in the United States. *J.A.M.A.* 104, 23:2083 (June 8), 1935.

What to Tell about Health—The author who listed 23 health "beliefs" to be unlearned now discusses what can be told in health education. In addition to nutrition, exercise and rest, he includes mental hygiene, poisons, parasites, accidents, and organ mal-

ASSOCIATION NEWS

NOMINATIONS FOR THE GOVERNING COUNCIL

IN accordance with the By-laws of the Association, the Nominating Committee reports the following nominations for the Governing Council. The Constitution provides that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to this list, pro-

viding such petition is received 15 days before the Annual Meeting."

The ten Fellows receiving the highest number of votes on a written ballot cast by the Fellows present and voting at the Annual Meeting in Milwaukee will be elected for the three-year term, 1935-1938.

NEW OFFICERS WESTERN BRANCH A.P.H.A.

THE following officers were elected
at the 6th Annual Meeting of the
Western Branch, in Helena, Mont.,
July 3, 1935:

President—W. F. Cogswell, M.D., Helena,
Mont.

President-Elect—H. E. Young, M.D., Vic-
toria, B. C., Canada

Vice-Presidents—J. D. Dunshee, M.D.,
Sacramento, Calif.; J. L. Jones, M.D., Salt
Lake City, Utah; and W. H. Kellogg, M.D.,
Berkeley, Calif.

Secretary—W. P. Shepard, M.D., San
Francisco, Calif.

Treasurer—William Ford Higby, San Fran-
cisco, Calif.

Regional Board—Guy S. Millberry, D.D.S.,
San Francisco, Calif.; George C. Truman,
M.D., Phoenix, Ariz.; Carl E. Green, Port-
land, Ore.; Fred Stimpert, Helena, Mont.;
Ernestine Schwab, San Francisco, Calif.;
John J. Sippy, M.D., Stockton, Calif., to
serve the unexpired term on the Regional
Board of Dr. Jones, who as a vice-president
is automatically a member of the Board.
This term expires in 1936.

Chairman of Executive Committee—Fred
Stimpert, Helena, Mont.

The 1936 meeting will be held in
Vancouver, B. C.

APPLICANTS FOR MEMBERSHIP

*The following individuals have applied for membership in the Association. They have
requested affiliation with the sections indicated.*

Health Officers Section

Robert W. Ball, M.D., P. O. Box 213, Colum-
bia, S. C., Richland County Health Director
Edgar Bieber, M.D., 501 Deer St., Dunkirk,
N. Y., City Health Officer

Pedro de la Camara, M.D., Centro Secun-
dario de Higiene Rural, Arevalo, Avila,
Spain, Health Officer

W. Taylor Chamberlin, M.D., 359 Fulton
Ave., Hempstead, L. I., N. Y., Health
Officer

Paul L. Eisele, M.D., Ripon, Wis., Health
Officer

J. W. Erwin, M.D., Savannah, Tenn., Health
Officer

Roscoe Faulkner, M.D., Trenton, Tenn., As-
sistant Director, Gibson County Health De-
partment

J. W. Frost, M.D., Box 245, Waverly, Tenn.,
Director, Humphreys County Health De-
partment

Robert K. Harker, M.D., Bridgeport, Calif.,
Mono County Health Officer

Austin E. Hill, M.D., Dallas County Health
Dept., Dallas, Tex., Assistant County Health
Officer

Charles E. Kaufman, M.D., 328 Main St.,
West Haven, Conn., Health Officer of West
Haven

Lester B. Lougee, M.D., Marilla, N. Y.,
Health Officer of Marilla and Elena

Will J. Martin, M.D., Kokomo Clinic,
Kokomo, Ind., City Health Commissioner

Sumner M. Miller, M.D., 800 Peoria Life
Bldg., Peoria, Ill., Commissioner of Health

Wilbur J. Moore, M.D., Cheshire, Conn.,
Health Officer

Edwin L. Sheahan, M.D., St. Louis County
Hospital, Clayton, Mo., Deputy State
Health Commissioner

John U. Speer, M.D., Pulaski, Tenn., Director,
Giles County Health Unit

Harry G. Timbres, M.D., Box 45, Reedsville,
W. Va., Physician, Arthurdale Homestead
Subsistence Project

Arthur J. Wiesender, M.D., 736 Spring St.,
Berlin, Wis., City Health Commissioner

A. Evan Williams, M.D., Boyceville, Wis.,
Health Officer

Laboratory Section

Claude S. Bryan, M.S., Michigan State Col-
lege, East Lansing, Mich., Research Worker,
Bacteriology Department

Mary E. Caldwell, Ph.D., Box 4051, Tucson,
Ariz., Head of Dept. of Bacteriology, Uni-
versity of Arizona

Marion S. Campbell, 29 N. Hawthorne Lane,
Indianapolis, Ind., Senior Bacteriologist and
Assistant Chemist, State Division of Public
Health

John Grill, M.D., 561 N. 15 St., Milwaukee,
Wis., Director of Laboratories, Milwaukee
County Institutions

Lewis R. Hill, M.D., 500 Sunset Ave., La
Grange, Ill., Assistant Professor of Bac-
teriology and Preventive Medicine, Loyola
Univ. College of Medicine; Pathologist

Dorcas O. Hoge, A.B., 512 W. Second St.,
Grand Island, Nebr., City Bacteriologist

Elizabeth D. Robinson, 1179 Main St., Hart-
ford, Conn., Senior Laboratory Technician,
State Dept. of Health Laboratories

Helen C. Sayles, B.A., Dept of Health, New
Britain, Conn., Bacteriologist

Thomas F. Walker, Great Falls, Mont.,
Director of Laboratory

Vital Statistics Section

Alexander Fell, Tenaflly, N. J., Secretary and
Registrar of Vital Statistics, Board of Health

Louise Hopwood, B.S., 615 Dunkirk Rd.,
Baltimore, Md., Statistical Worker, U. S.
Public Health Service

Sara Kerr, B.A., 126 Pearl St., Buffalo, N. Y.,
Consultant in Statistical Work, City Dept.
of Health

Frederick F. Stephan, M.A., 722 Woodward
Bldg., Washington, D. C., Secretary, Ameri-
can Statistical Association

Lida J. Usilton, M.A., 1613 Harvard St.,
N.W., Washington, D. C., Associate Statis-
tician, U. S. Public Health Service

Jane Worcester, A.B., 55 Shattuck St., Boston,
Mass., Statistician, Harvard School of
Public Health

Public Health Engineering Section

John F. O'Donnell, 4007 Holmes, Kansas City,
Mo., Farm Dairy Inspector, Health Depart-
ment

Food and Nutrition Section

Reid R. Ashworth, D.V.S., 3533 Hertford
Place, N.W., Washington, D. C., Chief Food
Inspector, Dept. of Health

Jacob W. Forbes, State Board of Health,
Helena, Mont., Director, Food and Drug
Division, State Board of Health

Lloyd B. Jensen, Swift & Co., Chicago, Ill.,
Chief Bacteriologist, Research Laboratories

C. J. Pollock, 1301 Moreau Drive, Jefferson
City, Mo., City Dairy Inspector

Child Hygiene Section

Fairfax Hall, M.D., 421 Huguenot St.,
New Rochelle, N. Y., New York State
Medical Society Committee Public Health
and Medical Education

Arie M. Wetzel, R.N., 210 Chestnut St.,
Marietta, Ohio, Washington County Public
Health Nurse

Robert G. White, M.D., Ann Arbor Public
Schools, Ann Arbor, Mich., School Phy-
sician

Charles C. Wilson, M.D., 249 High St., Hart-
ford, Conn., Director of Physical and
Health Education, Board of Education

Public Health Education Section

William J. Burns, 4421 Woodward Ave.,
Detroit, Mich., Executive Secretary, Wayne
County Medical Society

William H. Frazier, M.D., Tuskegee Institute,
Ala., Medical Examiner, Negro Public
Schools

Violet S. Hoar, R.N., 353 W. 17 St., Holland,
Mich., Health Counselor, Allegan County
Health Unit

Edward W. Zukauckas, M.D., 1114 Foster
Ave., Brooklyn, N. Y., Medical Inspector,
New York City Dept. of Health

Public Health Nursing Section

Florence W. Englesby, R.N., 800 Capitol Ave.,
Pierre, S. D., State Supervisor, Child Health
Nursing Project

Betty Jones, R.N., Savannah, Tenn., Hardin
County Health Nurse

Gladys McGuire, 822-6 Ave. N., Great Falls,
Mont., County Tuberculosis Nurse

Lily Morris, 2912-3rd Ave. N., Great Falls, Mont., Supervisor of School Nursing
 Stella I. Mucha, R.N., 134½ S. Barry St., Olean, N. Y., Supervising Nurse
 Ann S. Nyquist, R.N., University of Minnesota, Minneapolis, Minn., Field Nurse, Division of Child Hygiene
 Mary M. Ownby, R.N., Box 174, Waverly, Tenn., Humphreys County Public Health Nurse

Epidemiology Section

Ralph K. Collins, M.D., Direction Generale de la Sante Publique, Sofia, Bulgaria, Field Director, Rockefeller Foundation
 B. A. Dyar, M.D., State Board of Health, Pierre, S. D., Epidemiologist
 Joseph C. Knox, M.D., M.P.H., State Board of Health, Raleigh, N. C., Epidemiologist
 Earl B. McKinley, School of Medicine, George Washington University, 1335 H. St., N.W., Washington, D. C., Dean and Professor of Bacteriology, Hygiene and Preventive Medicine
 Dr. Carlos Monge, Calle Trinidad 373, Lima, Peru, Head Dept. of Medicine, Military Hospital
 Hugh F. Stanton, M.D., C.P.H., State Board of Health, Phoenix, Ariz., Epidemiologist
 Franklin H. Top, M.D., C.P.H., Herman

Kiefer Hospital, Detroit, Mich., Medical Epidemiologist

Thomas B. Turner, Rockefeller Institute, New York, N. Y., Special Member, International Health Division, Rockefeller Foundation

Unaffiliated

Frederic W. Nordsiek, S.B., 386 Fourth Ave., New York, N. Y., Executive Secretary, New York Diabetes Assn.

Joseph Stein, Room 1111, 330 W. 42 St., New York, N. Y.

ERRATUM

ON page 713 of the June issue of the *Journal* (Recommended Procedure for Diphtheria Immunization), the first word on the 29th line in the first column should be *years*, not months, the phrase thus reading, "The toxin-antitoxin mixture less often causes reactions in children over 6 years of age, and in adults, than do the soluble and alum precipitated toxoid preparations, . . ."

NEWS FROM THE FIELD

AWARD TO DR. CHESLEY

DURING the Conference of State and Provincial Health Authorities of North America held in Atlantic City, N. J., June 14-15, A. J. Chesley, M.D., F.A.P.H.A., of Minnesota, was presented with a certificate of award as State Health Officer of the state which had done the most to further the promotion of the Health Conservation Contests. The presentation address was made by Watson S. Rankin, M.D., F.A.P.H.A., Chairman of the Grading Committee of the Health Conservation Contest, on behalf of the Chamber of Commerce of the United States and the American Public Health Association.

At the time this award was announced by the Grading Committee special recognition was also made of the splendid interest being stimulated in the Health Conservation Contest by the New York State Department of Health. The success of these competitions is in no small measure due to the coöperation of state health officers all over the United States.

DES MOINES SURVEY

A BRIEF survey in regard to public health activities and organized care of the sick in Des Moines, Ia., was made recently by James Wallace, M.D., F.A.P.H.A., Associate Field Director of the American Public Health Association for the Community Chests and Councils, Inc.

BABIES HONOR DR. THOMPSON AT 100

MANY of the 1,800 babies he brought into the world during 75 years of practice thronged Main Street in Bethel, Ohio, on July 6, to celebrate

Dr. William Eberle Thompson's 100th birthday. The town weekly printed a special issue. The Ohio State Medical Association sent its president, Dr. John A. Caldwell of Cincinnati, to pay the respects of the profession.

Casting aside the honors, Dr. Thompson almost shyly called himself just an old-fashioned country doctor.—*New York Herald-Tribune*, July 8, 1935.

NORTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION ELECTS OFFICERS

AT its annual meeting in March, the Northern California Public Health Association elected the following officers:

President—Dr. J. C. Geiger, San Francisco
President-Elect—Dr. E. H. Coleman, Fresno
Vice-President—Samuel H. Greene, San Francisco

Secretary—Dr. I. O. Church, Oakland
Treasurer—Helen Hartley, Stockton
Representative on the Governing Council of the A.P.H.A.—Leon B. Reynolds, Stanford University

ROTHSCHILD GIFT

ONE of her last acts of philanthropy before the Baroness Edmond de Rothschild died recently was the contribution of \$7,500 to Hadassah, the Women's Zionist Organization of America, to repair the Hadassah Hospital in Safad, Palestine.

The property of the hospital building was given to Hadassah by the late Baron de Rothschild shortly after the World War and is the only hospital for tuberculous patients in Palestine. In the last few years the condition of the building had become so bad that the hospital would shortly have had to be condemned as unsafe. Extensive

repairs are now possible. It will have a bed capacity of 55.

ROOSEVELT MEDAL AWARDED

WILLIAM HALLOCK PARK, M.D., F.A.P.H.A., Director of the Bureau of Laboratories of the New York City Health Department, will receive the Roosevelt Medal for the year 1935. Dr. Park receives the medal for distinguished service in the administration of public office.

The medal will be bestowed by the President of the Roosevelt Memorial Association as usual at a banquet at Roosevelt House, the Roosevelt birthplace, at 28 East 20th Street, New York, on October 27, the 77th anniversary of Theodore Roosevelt's birth.

The Roosevelt Awards, which were established by the Roosevelt Memorial Association in 1923, are annually given in certain fields associated with Theodore Roosevelt's career: public and international law; industrial peace; science; American historical literature; outdoor life; national defense; international affairs; administration of public office; conservation of natural resources; advancement of social justice; expression of the pioneer virtues; leadership of youth and the development of American character.

STATE AND PROVINCIAL AUTHORITIES

THE following officers were elected at the Atlantic City meeting of the Conference of State and Provincial Health Authorities of North America on June 15:

President—Dr. H. E. Young, Provincial Officer of Health of British Columbia.

Vice-President—Dr. Earle G. Brown, Secretary of the State Board of Health of Kansas.

PERSONALS

DR. GREGORY D. MAHAR, of the staff of the Syracuse Department of Health since 1923, was appointed

Health Commissioner of Syracuse, succeeding Dr. George C. Ruhland, who recently became Health Commissioner of the District of Columbia.

DR. ELMER G. BALSAM, of Billings, Mont., is the new President of the Montana State Board of Health, and Dr. Louis H. Fligman, of Helena, is Vice-President.

DR. NATHANIEL W. FAXON recently resigned as Superintendent of Strong Memorial Hospital, of Rochester, N. Y., to become Superintendent of Massachusetts General Hospital, succeeding the late Dr. George H. Bigelow.

FRANCIS E. FRONCZAK, M.D., F.A.P.H.A., was honored at a reception recently on his completion of 25 years as Health Commissioner of Buffalo, N. Y.

DR. GEORGE M. ANDERSON, of Cheyenne, has been appointed to the offices of Wyoming State Health Officer, Secretary of the State Board of Health, and Acting Secretary of the State Board of Medical Examiners, succeeding Dr. Walter H. Hassed, member A.P.H.A. Dr. Anderson held the position prior to Dr. Hassed's appointment in 1928.

GAIUS E. HARMON, M.D., of Cleveland, O., F.A.P.H.A., has resigned as Associate Professor of Hygiene and Vital Statistics at Western Reserve University, to become Chief of the Bureau of Epidemiology of the Chicago Board of Health.

C. C. SLEMONS, M.D., F.A.P.H.A., who has served under 3 governors as State Health Commissioner of Michigan, was reappointed June 26. His term would have expired July 1. Dr. Slemons was City Health Officer in Grand Rapids before he was appointed State Health Commissioner.

DR. CHARLES M. SIEVER, for 19 years head of the Student Health Department at Kansas State College, Manhattan, Kans., resigned as of August

31. Dr. Siever was formerly Health Officer of Jackson County.

DR. EDWARD J. SCHWARTZ has resigned as Assistant Health Officer of the District of Columbia.

DR. HERBERT SPENCER GASSER, Professor of Physiology and Director of the Physiological Laboratories of Cornell University Medical College, has been appointed Director of the Rockefeller Institute for Medical Research, succeeding Dr. Simon Flexner, who is retiring.

DR. RALPH S. MUCKENFUSS, Bacteriologist at Washington University, St. Louis, Mo., until July 1, has become temporary Associate Director of the New York Bureau of Laboratories. From 1925 to 1929 he was connected with Rockefeller Institute.

I. F. THOMPSON, M.D., F.A.P.H.A., Commissioner of Health of Racine, Wis., has been reappointed for another term of four years beginning Oct. 1, 1935.

DEATHS

DR. THOMAS McCRAE, Professor of Medicine at Jefferson Medical College, Philadelphia, Pa., since 1912, and for more than 22 years a consulting physician in Philadelphia, died June 30, at the age of 65. He was a fellow of the Royal College of Physicians of England, a member of the British Medical Association, and a past president of the Association of American Physicians. Dr. McCrae collaborated with Sir William Osler in writing *Cancer of the Stomach*; and also *A System of Medicine*, which he later abridged into the 5-volume work known as *Modern Medicine*. After Sir William Osler's death he edited the latter's *Principles and Practice of Medicine*.

RALPH HENDRICKS, M.D., Health Officer of Spokane, Wash., died recently. He was a member of the A.P.H.A.

DR. CLARENCE JOSEPH D'ALTON, of New Milford, Conn., retired nerve specialist of New York City, died July 12. He served under Dr. Thomas W. Salmon in the U. S. Army Medical Corps during the World War, and was active in the work of The National Committee on Mental Hygiene.

CONFERENCES

Aug. 8-19, Fifteenth International Physiological Congress, Leningrad and Moscow, Russia.

Aug. 9, 10, North Pacific Pediatric Society, Seattle, Wash.

Aug. 10-17, Meeting of Health Section of the World Federation of Education Associations, Oxford, England.

Aug. 22-23, Central States Section of the American Water Works Association, Pittsburgh, Pa.

Aug. 29-Sept. 5, First Annual Meeting, Latin American Congress of Physical Therapy, X-ray, and Radium, Mexico City.

Sept. 20-Oct. 2, 7th International Medical Post-Graduate Congress, to be held during the World Exhibition, under the auspices of the University of Brussels, Bruxelles-Spa, Belgium.

Sept. 30-Oct. 4, American Hospital Association, St. Louis, Mo.

Sept. 30-Oct. 4, 21st National Recreation Congress, sponsored by the National Recreation Association, Chicago, Ill.

Oct. 5-7, Conference of State Sanitary Engineers, Milwaukee, Wis.

Oct. 7-10, Sixty-fourth Annual Meeting of the American Public Health Association, Milwaukee, Wis. Headquarters: Hotel Schroeder.

Oct. 7-10, Annual Meeting of the American Association of School Physicians, Milwaukee, Wis.

Oct. 7-10, Meeting of the American

Association of State Registration Executives, Milwaukee, Wis.

Oct. 7-10, Meeting of the International Association of Medical Health Officers, Milwaukee, Wis.

Oct. 7-10, State Laboratory Directors Conference, Milwaukee, Wis.

Oct. 7-10, Conference of Wisconsin Health Officers, Milwaukee, Wis.

Oct. 8-11, Meeting of the Association of Dairy, Food and Drug Officials, Milwaukee, Wis.

Oct. 10-11, Meeting of the International Association of Dairy and Milk Inspectors, Milwaukee, Wis.

Oct. 14-18, 24th Annual Safety Congress, National Safety Council, Inc., Louisville, Ky.

Oct. 28-31, 18th Annual Meeting, American Dietetic Association, Cleveland, O.

Nov. 1, 2, School Health Conference, sponsored by the Department of School Health and Physical Education of the National Education Association, Philadelphia, Pa.

Nov. 15, 16, Sixty-first Annual Meet-

ing, New Jersey Health and Sanitary Association, Hotel Berkeley-Carteret, Asbury Park, N. J.

Nov. 19, 20, Annual Meeting of the Southern Branch, American Public Health Association, St. Louis, Mo.

Dec. 30-Jan. 4, 1936, Winter Meeting of the American Association for the Advancement of Science and Associated Societies, St. Louis, Mo.

July 27-31, 1936, Second International Congress on Mental Hygiene, Paris.

Sanitation in the Holy Land*

ISADOR W. MENDELSON, F.A.P.H.A.

New York, N. Y.

IN the short span of 15 years, historic Palestine has emerged, from a war-torn, oriental country infested with malaria, trachoma, and other infectious diseases, as one of the very few prosperous sections of the world. The illuminating story of this remarkable metamorphosis is one of consistent progress in public health and sanitation matching economic development, step by step. Credit for this achievement is due the British Department of Health of Palestine, Louis J. Cantor of New York City who was its first sanitary engineer, and the Hadassah, Women's Medical Auxiliary of the Zionist Organization of America.

Before their retreat in 1917-1918, the Turkish Army, following the example of other armies during the great war, deliberately wrecked the country, ravaging the homesteads, and conscripting the population or sending it into exile, leaving behind the weak, the old, and the very young. The land was denuded of stocks of cattle and horses; orange groves were ruined by lack of irrigation; and cultivated fields were abandoned.

The war's depredations in Palestinian towns are mirrored in the harrowing experiences of Petah Tikvah. Forty years before, that inspired Joshua Stemper, who was loved even by his opponents, had walked from his birth-place in Hungary to Jerusalem and, though the son of a Rabbi and untrained as a cultivator, had founded the colony of Petah Tikvah. It developed splendidly under the Palestine sun, the transformation of every parcel of sand into bearing vineyards and orange groves arousing great joy among the educated but manually untrained young farm hands. Then came the war and the colony's tragic decline; the requisition of cattle and other possessions, and the ruthless cutting of trees by the Turks and the Germans to run their locomotives; the destruction of all crops by clouds of locusts making night of day; invasion by warring armies, twice by the Turks, twice by the English, and four times the scene of battle; the evacuation of the population and, finally, their return to empty houses in October, 1918. In the intervening months, the exiles were driven from place to place, sleeping in the open, sick and weary; their bodies unutterably filthy with sores and wounds; their every possession sold, lost, or stolen.

* Much of the foregoing information was obtained through the courtesy and assistance of Mrs. Cantor, the American Economic Committee of Palestine, and the Hadassah, for which the writer is deeply grateful.

In Jerusalem the Jewish population was in the most precarious position of all. Composed largely of old men and women devoted to study and prayer who had come, with insufficient funds, to spend their last days in the Holy City and to be buried on the Mount of Olives, scores died of sheer want after their monthly subventions from Europe and America were cut off by the war. Serious outbreaks of disease reduced their number still further, leaving weak and dispirited survivors. Their vicissitudes reduced the Jewish population in the city to 32,000 early in 1919, half what it was before the war, and among them approximately 1 in every 10 was an orphan.

Immediately following British occupation of Jerusalem on December 11, 1917, the Occupied Enemy Territorial Administration (O.E.T.A.) was organized, with military governors at Jerusalem and elsewhere; food was brought by military transport, and merchants were permitted to import goods from Egypt via the military railway. Among the most urgent tasks of the O.E.T.A. was the development of a Medical and Health Service in the country ravaged by war and decimated by disease. Few traces were found of any preëxisting government health service—in theory there existed under the Ottoman Code the outline of an organization which would have served the primary needs of the country, if in practice it had been adopted but, beyond the employment of part-time municipal doctors on small retaining fees, little was done. Within a year the new Department of Health, assisted by the Hadassah Medical Unit, and for a time the American Red Cross, established and actually conducted in nearly all the larger towns their sanitary services, instituted an epidemic and disinfection program, laid the foundations of an anti-malarial organization embracing all towns and colleges, and founded a central hygienic

laboratory at Haifa, with branch laboratories at the government hospitals in Jerusalem, Jaffa, Gaza, and Nablus.

To supplement government health and social activities, the English agreed to the despatch of a Zionist Commission to Palestine to form a link between the British authority and the Jewish population and to coördinate their relief work and other efforts; also, to the sending of an American Medical Unit by the Hadassah to assist their coreligionists with urgently needed medical relief. Such is the story of the official existence of the present activities of these groups in Palestine in assisting not alone Jews but also Arabs and Christians in the daily amenities of life, particularly medical relief and sanitation.

With the American Medical Unit of 20 doctors and 20 nurses was a sanitary engineer, Louis J. Cantor, chosen because of his anti-malaria experience with the United States Government in the Panama Canal Zone and destined because of his inspired, unflagging, zealous efforts in the face of innumerable difficulties to become the pioneer sanitation engineer of Palestine.

On August 8, 1918, the unit arrived at Jerusalem while the world was still at war. The sanitary engineer was at once assigned to the 123rd Sanitary Section of the British Royal Army Medical Corps for direct army control of anti-malarial work, scavenging, and food establishments in Jerusalem. Noting that the overburdened hospitals were filled with malaria patients and the city saturated with mosquito propagating cisterns and water receptacles, Cantor asked for and received 6, later increased to 12, Jewish soldiers of the 39th Battalion, Royal Fusiliers, as sanitary inspectors. He immediately instituted a thorough search for all mosquito-bearing water containers, and began their oiling to prevent the innumerable eggs from developing in

the embryo stages in the vitally necessary water. Garbed in their uniforms, invested with the authority of the British Army, and conversant with Eastern ways and languages, the inspectors sprayed cisterns, cesspools, drains, leaders, water-jars, overhead water reservoirs, and rain barrels in gardens with a special crude oil mixture provided by the unit. Cursed alike by the Arab and the Jew who did not want their sweet-tasting water fouled with the oil, and at times showered with water and over-ripe vegetables by irate householders, the inspectors stoically proceeded with their spraying. In the case of an old woman, this tumultuous greeting of the inspectors was replaced with a quiescence almost of welcome. Upon investigation the paradoxical situation was solved. After the inspector sprayed the surface of the water in the open cistern which in common with most others in the city had a rope and pail but no pump, the crafty woman inserted a cloth, sopped up the oil and squeezed it into a vessel. Later she fed the reclaimed oil to her kerosene stove which is universally used for cooking in Palestine. Despite similar rebuffs, the results of this campaign were immediate and astounding; the number of malaria deaths in the city decreased from 113 in the last 9 months of 1918, to 35 for the year 1919, and to 5 for all 1922. When viewed in the light that for each malaria death there are hundreds of malaria cases, the reduction in human suffering in Jerusalem can better be appreciated.

But oiling was expensive and had to be continued weekly. To exclude the female mosquito from the water, a movement was begun to persuade the householder to cement the top of his cistern and attach a hand pump. The few well-to-do did so at once, but the poor could not afford the expense involved. Cantor induced the Hadassah to purchase 10,000 hand pumps and

Laying sewer line in Meashorim

make them available for general distribution through the government at a nominal charge. This action proved of incalculable value. But there were still many who persisted in the customary use of the open cistern. At last it was necessary to resort to sterner measures. On November 16, 1919, a notice was published in the *Official Gazette* that—

The public water supply is only available for the Army, Railroad, Institutions, and necessary trades. Therefore, it is necessary for the public to use cisterns and maintain same with cover or pump in a sanitary condition on fine of £5 or imprisonment of one month; and the Military Governor, if he thinks fit, can have the work carried out and charge the expense to the owner or occupier.

Gradual enforcement of this order brought the desired results.

With his energetic sanitary inspectors, Cantor supervised the frequent collection of house, trade, market, and street refuse, loading it in bags atop donkeys—according to the practice of the ancients—hauling to dump grounds

outside the city and burning it in small incinerators. In cleaning up the Jewish quarters, relief funds were assigned through the Zionist Commission to provide work under Cantor's direction for the unemployed old Jews ranging in years from 40 to 70. At the maximum, 110 of these laborers were employed.

To overcome the carefree public custom of throwing garbage into the street oblivious of passers-by and at times spattering them, or dumping it in open kerosene tin cans, the Department of Health on Cantor's recommendation required the householder to provide suitable garbage containers. A model garbage can with cover was made and displayed in his office and throughout the city. This was followed by a campaign of persuasion resulting in their widespread installation. The public demand from all Palestine for garbage cans is now being supplied by a factory in Tel-Aviv.

The Hadassah Medical Unit was originally housed in the Baron de Rothschild Hospital at Jerusalem. Immediate renovation of this hospital and construction of additional service buildings was the first of Cantor's major assignments. A hurried survey of available means for this building project was disheartening and showed, in the words of Cantor's diary,

Labor available—old men and boys (able-bodied men in the army), no mechanics nor skilled workmen; materials—stone (badly dressed), lime (not burned), wood (not obtainable), roof tile (demolish buildings), water supply (cisterns, goat skins, and petrol tins), glass (priceless), paint (expensive), tin (use petrol tins), timber (dismantle old buildings); transportation—porters for lumber and glass, donkeys for sand and stone, camels for tiles and cement, wagons for lumber, cement, and stone, and automobiles for general duty.

But Cantor undaunted carried on. From the wood of the 1,883 cases of freight containing the Unit's supplies which arrived in September, chairs, tables, hospital shelving, and other

articles were made. Finding among his soldier inspectors one with a working knowledge of plumbing, he taught a few local tinsmiths—the only skilled laborers available—how to do simple plumbing operations. Masons and carpenters were developed to carry out his ideas. Supplies were obtained by dismantling old buildings, from the Unit's freight when available, by purchase from the British Army or the American Red Cross, or by personal trips to Cairo. From all this there was developed in a short time a completely renovated main hospital building having clinics and dispensary provided with modern hospital equipment, such as X-ray and disinfecting machines, and with water for a hot and cold system for baths, showers, lavatories, and sterilizers; latrines; a laundry building; a morgue; storehouse; garage; laboratory; nurses' home; and headquarters.

Next came the cleaning and renovation of existing Jewish hospitals, orphanages, schools, and other public institutions including Mikvehs or baths. To the consternation of the orthodox Jews, the bathing pools in the Mikvehs were treated by the inspectors with bleaching powder to destroy infectious germs, and bathers contrary to life-long habits were required to soap themselves and take a thorough shower before entering the pools. To show orthodox students that the clusters of long hair growing on their cheeks in the form of "payas" or side-burns and acting as dirt and disease-germ catch-alls could be maintained in a sanitary manner despite the religious prohibition against cutting them with a knife, Cantor grew them for a year and had them trimmed with scissors. Because of increasing public demand for modern plumbing and Cantor's persuasion and unfailing assistance, the local tinsmiths and hardware stores, within a year and for the first time in the history of Palestine, made available to the public the various

appurtenances known as modern plumbing. Today well equipped stores in Jerusalem and elsewhere in Palestine display the products of large sanitary supply firms of both Europe and America, and a factory in Tel-Aviv is manufacturing sewer tile.

At the same time that Cantor commenced his sanitary work in Jerusalem, Dr. S. M. Schmidt of the Unit originated similar work in Jaffa, all under the authority and supervision and with the coöperation of the O.E.T.A. The first operation was a house-to-house medical and sanitary survey which revealed the need for scavenging, inspection, distribution of insecticides, and rat and mouse traps, screening, and oiling of wells. About 1,600 wells were sprayed. After a considerable number of men had been trained as sanitary inspectors, including some for anti-malaria operations in Haifa, the Unit was charged with the sanitation of 10 military camps and billets, and was assigned by the Municipality of Jaffa to the inspection of cafés, bakeries, barber shops, and other public buildings. Latrines were set up for the use of the Egyptian labor corps employed by the O.E.T.A. In a few months the persistent oiling caused a great reduction in the number of malaria-mosquito infested places.

About the middle of October one of Jaffa's sanitary squads was sent to Tiberias to combat the outbreak of cholera which before its termination caused 60 deaths. The source of infection was the water supply from the Sea of Galilee on whose shore the town is located. The lake was polluted with street washings, direct defilement by persons defecating in it, bathing and fishing. Jugs and kerosene tins were filled with this water, which was practically the only supply at the time, and carried to the houses. In controlling the epidemic, the British fenced off the entire city shore line with a wire netting,

leaving but five stations for taking water. These were constantly protected against pollution. When a water carrier left one, a sanitary inspector placed bleaching powder in the container. Ten houses on the lake were evacuated to guard against pollution of the water. Empty lots were closed up, streets

Sewage treatment plant in Wady Joz

cleaned, and latrines and other nuisances abated. Anti-mosquito measures were adopted and carried through rigidly with the backing of the O.E.T.A.

Unfortunately, with the termination of the epidemic, the city resumed its ancient customs. An inspection by Cantor early in 1922 disclosed general sanitary negligence; the barricades to the lake had almost all been removed; the vacated lake houses opened; animals were being cleaned at the point of water supply; mosque latrines were emptying into the lake near the water pump; and the water was being taken at all points without any supervision. Action was quickly instituted to remedy these insanitary conditions.

Another sanitary squad was sent by the Jaffa Unit to Safed early in 1919. Schools, orphanages, and other public buildings were cleaned; necessary scavenging accomplished; houses and yards inspected; and cisterns oiled, sealed, and marked.

When Dr. Schmidt left the country in July, 1919, Cantor was placed in charge of all the Unit's sanitary activi-

ties in Palestine. Gradually, as trained personnel were provided for municipal sanitary services, the Unit's efforts were concentrated on sanitary improvements and anti-malaria activities in the Jewish agricultural colonies. Daily inspections were made of houses, yards, and water supplies of all the colonies, and a house-to-house educational program was conducted. In view of the large and increasing immigration through Jaffa, an immigrant delousing plant was established there. Immigrants were distributed among various labor camps whose sanitation was supervised by Cantor's inspectors.

In the meantime the O.E.T.A. through the Royal Engineer Corps made a health survey and census of Jerusalem. In the Jewish quarters this was accomplished by the government-loaned inspectors. With a view to installing a new system to improve the offensive sewerage conditions, cistern data were obtained, first for the northwestern section, and then the old or walled city. Certain cisterns would be used to flush proposed sewer lines, due to the inadequate city water supply.

Upon the survey's completion, Cantor was appointed sanitary engineer in charge of design and construction of the sewerage system for the northwest district, in addition to his other activities. The Zionist Commission donated \$50,000 for this project, and the O.E.T.A. granted \$10,000 for the treatment plant. Surveys were made, the system was planned, and the project presented to the city and O.E.T.A. for approval.

But at this point the scheme was almost defeated. When permission to purchase the land for the treatment works was sought from the Arab Mayor, he at first refused. His father and grandfather had lived in Jerusalem and had found a cesspit satisfactory, why should there be any change? Finally, approval was granted.

During its construction innumerable

difficulties were overcome. Supplies had to be purchased in Cairo and transported to Jerusalem. Skilled labor had to be procured. Arabs, the only workmen practised in the use of dynamite, were employed under an experienced Arab foreman in blasting a trench for the sewer pipe through the rock of the streets of the old orthodox Jewish quarter, Meashorim, meaning Hundred Gates. The 100 gates did not let in light or clean air, though. The streets were lean and crooked, the houses decrepit. The smells were of the vilest and most persistent.

Then followed a great religious controversy. True Arabs observe their day of rest on Friday, the orthodox Jews on Saturday. Not to lose time or money in construction, blasting was continued even on Saturday when Jewish services were being conducted. The Rabbis complained bitterly, to Cantor most of all, for he was in charge. But he could not delay the work, the funds were insufficient to provide for the extra expense involved. So the Rabbis solemnly proclaimed "Herem" (Hebrew word meaning outcast of the community), thereby excommunicating Cantor who was of their faith, forbidding God-fearing Jews to have anything to do with him. It was not until a year later, after the system was working and the offensive drainage conditions had been removed, that the Rabbis and the whole district publicly acclaimed Cantor for this achievement.

So the work progressed, the treatment plant was installed, and the completed project was turned over to the Municipality of Jerusalem in an official ceremony on November 12, 1920.

Somehow the troubles did not cease. Because the funds were inadequate and the works were to be temporary, until the large city sewerage scheme was perfected, the treatment plant was placed in the Wady Joz. This location was just below the hill on which were some

fine residences including the Mayor's and several English officials'. Complaint of offensive odors from the treatment plant ascribed to poor construction was lodged with the Mayor. He in turn complained to the British Government, making of it a political issue, to the effect that the Jews were trying to poison the Arab neighborhood and were creating a nuisance involving the spread of disease. So persistent and so influentially pressed was this complaint that the matter became a government issue. The government requested of Egypt that a sanitary engineering expert be sent to Jerusalem to investigate the situation. This was complied with and the sanitary engineer in time made the investigation and reported that the treatment works should be located farther down the valley. But money was not available for this; so the plant has remained in the same spot to this day. However, with the construction of the larger drainage system begun in 1932, the temporary works will be replaced by an adequate plant in the Valley of Kidron.

At present the only rivulet at Jerusalem is the effluent flowing from the sewage treatment plant in the Wady Joz. Strange to say, Arab women who enjoy picnics hold these functions beside this stream where it passes through the valley of olive trees and vegetable gardens.

Another example of the insanitary conditions under which the people of Jerusalem lived at the time of the O.E.T.A. is furnished by the memorable experience with the greatest snowfall in the city in 40 years. On February 10, 1920, there began a snowstorm without let-up until the 13th. More than 4 feet of snow fell. No one left his house the first day. On the next Cantor, knowing of the sick and poor in the Jewish quarters and the damage that would follow when the melting snow would flood the lowlands, en-

deavored to enlist help from the Rothschild Hospital. However, the attendants who were orthodox Jews refused to assist in removing the snow. They said they could not remove what God had sent from Heaven, it would be sacrilegious. But the doctors saw the need and cleared paths through the snow from different pavilions of the hospital. Cantor was placed in charge of relief work by the Unit. Doctors were assigned to various districts to visit the sick. Finding the bakery closed and without flour, Cantor asked the Governor for and obtained the loan of animals from the Department of Health, purchased flour, brought it to the baker, and then distributed the bread to various snowbound houses, using the willing Maccabean youths with donkeys. From the British Army he obtained soldiers to clear paths in the snow.

The snow was so heavy that the overburdened roofs of the Unit Nurses' Home and many other houses collapsed. All night long on the 12th, the doctors worked the pumps at their home and the hospital discharging water from the overflowing cisterns beneath the dining rooms to prevent flooding of the buildings. Snow was removed from house roofs. Weakened buildings were braced. Dwellers in low sections which might be flooded were moved to higher sections and temporarily housed. By the 14th paths were extended to the main streets, ditches opened for the melted snow water, families rescued from falling buildings, and a thorough canvass made of the districts, using the men and horses obtained from the O.E.T.A. On the next day, Sunday, with the snow generally melting, the city was subdivided into districts, 43 pumps with crews assigned for emptying overflowing cisterns, and labor gangs designated to help the sufferers, reinforce the weakened buildings and demolish dangerous dwellings with ropes. Over 100 workers cleared the

debris in the old city where some buildings collapsed in the week following the snow storm, killing several occupants. In this manner the great storm passed, leaving comparatively little public suffering and flooding of buildings in its wake.

Street of Prophets under snow, Jerusalem

Other activities of the indefatigable Cantor in the first 2 years may be likened to the development of an army to combat disease, including the training of chauffeurs in the hospital garage and of sanitary inspectors; conducting evening technical courses for developing draftsmen, foremen, and surveyors; and operating an employment agency and relief department for the Unit.

With the installation of the British Civil Administration on July 1, 1920, Cantor was appointed Sanitary Engineer of the Government Department of Health in recognition of his achievements. Without an office or furniture except for a table, he borrowed a chair and some paper and outlined his organization for the Sanitary Section. In time this included an assistant sanitary engineer, a draftsman, plumbing and sanitary inspector, a clerk, and a Museum of Sanitation. Its multiple activities included anti-malarial measures; sanitation of all government and public buildings; preparation of plans for model dairies and food establishments of all kinds; coöperation with municipal and village governments in

water supply, drainage, scavenging, and supervision of trades and industries; and general dissemination of sanitation information.

One of the first accomplishments of the new Department of Health was the appointment of a permanent Anti-Malarial Advisory Committee in September, 1920. For centuries malaria had decimated the population and barred the development of large tracts of fertile land. At times it assumed epidemic magnitude wiping out in the space of a few months the populations of whole villages. Few regions in Palestine were wholly free from it before the war. Every autumn hospitals in Jerusalem and most of the other towns were crowded with malaria patients. Anti-malarial government measures were carried out by the Sanitary Section. Necessary funds were provided and other assistance was rendered by a Survey Section of the International Board of Health and the Malarial Research Unit of the Jewish Joint Distribution Committee.

The Rothschild Foundation drained the Kabbara swamp between Jaffa and Haifa. Jewish agricultural colonies and towns drained nearby marshes and pools. Wells were covered. By 1925, more than 105 miles of drainage canals and ditches affecting 5,574 acres had been constructed, and 45,000 wells, cisterns, and cesspits were being oiled regularly. The malaria mosquito had disappeared from all the large cities except Haifa, and new cases of malaria were rare in them. A vivid picture of the transformation accruing from these efforts in the important Valley of Esdraelon is given by Sir Herbert Samuel, first English High Commissioner, in the following words:

When I first saw it in 1920 it was a desolation. Four or five small and squalid Arab villages, long distances apart. . . . For the rest the country was uninhabited. There was not a house, not a tree. . . . The River Kishon, which flows through the valley

and the many springs which feed it from the hillsides, had been allowed to form a series of swamps and marshes, and, as a consequence, the country was infested with malaria. Since then, 20 villages have been founded with a population numbering 2,600. . . . All the swamps and marshes have been drained, and cases of malaria are proportionately rare. The wooden huts of villages . . . the plantations of rapidly growing eucalyptus trees . . . fields of vegetables or cereals cover many miles of land.

Today in most Palestinian cities malaria has been brought under control by the Department of Health. Persistent drainage measures have practically conquered the disease in Jewish and neighboring Arab villages, while in non-Jewish areas (Acre, Huleh plain, and the region east of Beisan) malaria is still rampant. In rural and certain urban communities, much remains to be done.

Through efforts of the Department of Health, a Town Planning Ordinance was passed in 1921 establishing a Central Town Planning Commission to supervise new building construction in town areas. These buildings were to be provided with approved types of sanitary facilities. Under this ordinance, local town planning committees were formed in Jerusalem, Jaffa, and other cities. Model sanitary by-laws prepared by the sanitary section were approved by the commission for adoption by the cities, and a model plumbing code similarly prepared was published in the three official languages—Arabic, Hebrew, and English—by authority of the Commission.

Finding unsatisfactory plumbing installations being made by tinsmiths, locksmiths, and blacksmiths, due to the great scarcity of qualified plumbers, Cantor established a plumbing course in Tel-Aviv in 1926. At its conclusion, an examination was held. Thirty-five qualified to practise as plumbers, and 60 men were classified as assistants. Because of its success it was established as an annual institution. Similar courses were given in Jaffa in 1928 and

in Jerusalem and Haifa in 1930. In 7 years, 85 candidates were awarded certificates to practise as plumbers. For instructing classes in plumbing at the Haifa Technical Institute, Montefiore Technical School in Tel-Aviv, and the new Y.M.C.A. in Jerusalem, syllabi and sets of drawings of standard sanitary installations were provided. Defective plumbing material foisted on the country at the beginning was gradually replaced. So much good resulted from these efforts, that the Director of the Department of Health in 1929 stated:

The training and examination of plumbers undertaken by the Sanitary Engineer of the Department has had considerable influence in the improvement in house drainage.

An interesting experiment in social hygiene and domestic medical education was successfully encompassed in the first Palestine Health Week, November 23–30, 1924. The idea originated with the Hadassah which bore all expenses, was fostered by the Government,

Part of sewage treatment plant showing screens for removing coarse floating matter

and assisted by 25 leading local groups. Through the Government Department of Education, teachers talked in 716 schools in 353 cities, towns, and villages, on the daily health topics—Health, Baby, Food, Microbe, Recreation—and distributed pamphlets in Arabic and Hebrew to the pupils. Lectures and demonstrations were delivered at meetings of parents. A contemplated Prize Baby Competition was cancelled because of the superstition prevailing among mothers that personal exhibition of their babies would work to their physical harm.

A Health Exhibition to exemplify by demonstration and models the lessons indicated by Health Week was opened in Jerusalem on November 17, 1924, by the High Commissioner and visited in the 2 following weeks by no less than 34,090 people, including 4,830 children, an extraordinary attendance mark for a city of 65,000. The Government loaned the Sanitary Engineer, as Chairman of the Exhibition Committee, and his staff for 3 weeks to prepare and supervise the exhibition material. The Department of Health assisted in furnishing demonstrators in charge of several of the 14 sections and loaning equipment, including a complete mobile unit for combating disease epidemics. A special Harem Day was designated for Moslem women when only women demonstrators and guides were present. Many attended, lifting their veils and touching the exhibits, being deeply impressed through such physical handling.

Early in 1925 at the request of the Zionist Commission, the Department of Health sent Cantor as its representative on their committee to advise on the sanitation of all Jewish colonies in the Emek Valley. Many insanitary conditions were found, particularly the privies. Various improvements were recommended in a private conference with the colony leaders. Despite the

seeming fact that Arabs were immune to certain infectious diseases and Jewish immigrants not, these recommendations were not acted on. It was claimed they would prove a hardship on the colonies, were not required of the Arabs by the Government, and would be unfair. That summer a severe outbreak of typhoid fever occurred among these colonists, causing 192 cases and many deaths.

From the very beginning of the British occupation, water was scarce in Jerusalem, despite the 5,300 cisterns. To provide sufficient drinking water for the army, a pipe line was laid for over 13 miles, from Solomon's Pools to the city. Still the supply was insufficient. In 4 months the British Army Engineers rehabilitated the old unused aqueduct constructed by Pontius Pilate and brought water through its 40 miles of winding conduit from Ain Arrub springs. As abnormally low rainfalls decreased the supply, in 1923 water was transported by motor lorry from Nablus and other towns. Dirty Arabs peddled water from donkeys laden with six 4 gallon kerosene tins filled at the large cistern in the sacred Haram Sharif Area, charging 25 cents per tin. Those unable to pay these exorbitant prices waited patiently in queues at neighborhood standpipes from early morning until the special attendant's arrival to obtain the two tins of 8 gallons allotted each family every 2 or 3 days at a cost of 1 cent for 4 gallons. Only those possessing a ticket obtained from the Municipal Government showing the number of members in a family were provided with this water. The fee was used to pay the attendant's salary, there being a number of them who for one hour during the appointed day turned on the water from a neighborhood standpipe.

To relieve the sorely pressed city further, the Government in May, 1925, passed the Urtas Spring Ordinance to provide water from the Arab spring of

Urtas Village for a temporary period of 12 months by the construction of suitable works and pipe lines to Solomon's Pools. The city took only part of the water from this spring, the villagers having more than sufficient for their limited domestic wants and for irrigating their apricot orchards, vineyards, and fields. Compensation was made by the city on account of complaints of the villagers of possible damage to their crops from such diversion.

Nevertheless the ordinance proved a great shock to the villagers. They claimed the spring was theirs, and no one had a right to usurp their property. They said the water was taken for Jewish building purposes in Jerusalem, and pointed to the large amount of building in progress at the time to substantiate this accusation. The Executive Committee of the Palestine Arab Congress sent a long communication of protest to the Secretary of State for colonies in London. The inhabitants of Urtas brought suit to restrain the Government from using the spring. They claimed the ordinance was void because it failed to respect Arab rights guaranteed by the Mandate. The case came before the Supreme Court of Palestine. The Court held the ordinance repugnant to and inconsistent with the Mandate, because it failed to safeguard the civil rights of all the inhabitants, and declared it invalid. Appeal was made by the Government to the Judicial Committee of the Privy Council which reversed the Court's decision regarding the specific situation, holding that "there is no suggestion that any such discrimination is to be found in the Ordinance now under consideration."

The rainfall proving inadequate in 1926, water was hauled by train from Lydda. In later years additional supplies were piped from nearby springs, Ain Farah, Ain Fawar, and Wadi Kelt, but to little avail. The rapidly growing

Scavenging cesspools—June 8, 1919, at Orphan Relief Department. Insanitary nuisance to be replaced with Merryweather vacuum collection system.

population and low rainfall were too much for the available supplies. Finally, in accordance with the recommendations of the Municipal Water Department, concurred in by the Department of Health, a new supply from Ras-el-Ain springs at the head of the Auja River north of Jaffa was approved, money provided, and construction of the necessary pipe line and pumping stations begun in 1933. This water will be pumped 37 miles and raised 2,635 feet at a cost approximating $1\frac{1}{2}$ million dollars, and will be sold to the public at the comparatively high price of 10 or 11 gallons for 1 cent (in New York City the householder pays that for 80 gallons).

It was Cantor's practice when finding insanitary conditions in cities, to try out remedial measures in Tel-Aviv or elsewhere. When they were successful, he would endeavor to have the Department of Health adopt them for the country. Gradually, as a result, the cities undertook, with municipal funds, such sanitary services as giving way to a and maintenance of a of structure, with and equipment, street, the architectural drainage and water ple were adopting a partment of Health of view. posed to past prac, allpox had become a tracts for scavengi

pal services. All such sanitary services were inspected regularly whether in towns or villages. However, to insure more constant supervision in the larger cities, Cantor recommended the appointment of Municipal Surveyors. This was approved by the Government, and Municipal Surveyors were provided in Jerusalem, Haifa, and Jaffa. In Tel-Aviv this supervision was arranged for through a qualified plumbing inspector. For villages his recommendation of the appointment of a Local Council to supervise sanitation was adopted, and several such bodies were designated.

Finding that trade and industrial establishments were increasing rapidly without due consideration of sanitary principles, the sanitary section worked for a law to provide necessary safeguards. In 1927 an Ordinance for Licensing and Control of Trades and Industries was enacted with general supervision over its application vested in the Department of Health, more specifically, the Sanitary Engineer's Office. Before a new building coming under this classification was erected, the plans were laid before this Office for approval as to structural, safety, and sanitary provisions. Before it was placed in operation, it had to receive such approval again, always after a personal inspection. In the case of a cinema in Jerusalem, the builder complained because of the requirement of providing a suitable number of separate closets for men and for women. He stated his theatre was not for that purpose and that the requirement was more stringent than in Paris. In due time, he was persuaded as to the desirability of the requirement.

sanitation of a
Emek Valley.
ditions were for
privies. Various
recommended in a
with the colony le

Similarly, the Sanitation Section instituted activities tending to provide good water and drainage facilities and cleanliness in public restaurants, hotels, and other food establishments. Such efforts were directly reflected in the decrease in dysentery cases in Petah Tikvah from 63 in 1927, to 13 in 1930. The Director of the Department of Health, referring to this work, said in 1930:

The control of drainage, ventilation, and sanitary conditions in hotels, restaurants, and cafes, which, in so many countries in the East are the source of disease, has reduced to a minimum the apprehensions of tourists and visitors who are so important a source of the revenue of the country, and has developed in the proprietors and their local clientele a sense of cleanliness and hygiene unknown a few years ago in Palestine. The department has little difficulty now in obtaining reasonable sanitation in old establishments, and a high standard in new. The people themselves are beginning to demand it.

NOTE: Louis J. Cantor, whose work in Palestine is described in this paper, died there on January 8, 1933. That he was the father of sanitation in the Holy Land, no one can deny. Colonel Herron, Director of the Department of Health, summed up Cantor's achievements at the time of his death in these words: "His wide and accurate knowledge of a great variety of subjects dealing with Public Health have been of the greatest value in guiding developments in Palestine on correct lines.

"His splendid work is reflected especially in the very remarkable improvement in the plumbing, drainage, and sanitary installations in private and public buildings and in trades and industries, which has been such a feature throughout Palestine and which has so effectively reduced the incidence of preventable diseases. His achievements will live after him."

School Health Problems Through the Years: Boston Public Schools 1635-1935

JOHN P. SULLIVAN, PH.D., F.A.P.H.A.

Supervisor of Health Education, Boston School Department, Boston, Mass.

THIS year is of historical significance in the educational world since it marks the 300th anniversary of public school education in America. Here in Boston in the year 1635, only five years after the landing of the Puritans, Boston Latin School was founded. As Supervisor of Health Education, I was particularly interested in the health history of the Boston Public Schools through the years. An intensive study of the original records brought to light some very illuminating points on health.

The evolution of the Boston Public Schools from the first simply constructed building in which the Puritan scholars of early Boston assembled to study Latin and Greek, to the imposing modern structures, is replete with many examples of the progress made in safeguarding and supervising the mental and physical welfare of the pupils. In fact the progress made closely parallels the improved mortality and morbidity status of Boston.

The first two centuries of Boston's growth saw but few schools and a comparatively small school population. From 1635 with an enrollment of 75 scholars,¹ to 1700 with a school population of approximately 320 scholars assembled in 3 buildings,² the school system grew, until 1800, when there were about 1,100 scholars housed in 7 structures.³ The present system comprises over 325 school buildings with

an approximate enrollment of 140,000 pupils, a school enrollment larger than the total population of one far western state.

For the first three-quarters of a century, school work consisted chiefly of stressing the classics so that the young scholars might be acquainted with the Scriptures in the original. Very little attention was given to the hygienic conditions of school surroundings or the physical welfare of the scholars. Most attention was given to the imparting of knowledge rather than the conditions under which the knowledge was imparted. The general welfare of the citizens and pupils was in the hands of the Selectmen.⁴ It is of general educational interest to know that the first public health officer in Boston was Paul Revere.⁵

Keeping the footpaths free from refuse, fear of fire, and the pestilence, as smallpox was called, were the real community health and safety problems confronting the Selectmen of Colonial Boston.⁶ But about 1700, the Town of Boston was outgrowing its village atmosphere; streets were beginning to replace footpaths; the first rudely constructed homes were giving way to a more substantial type of structure, with a semblance of some architectural design; and the people were adopting a more social point of view.

Meanwhile, smallpox had become a

major health problem. Epidemics were becoming frequent. In desperation, the Selectmen issued an order on March 9, 1729, encouraging inoculation against this pestilence.⁷ This order did not seem to carry much weight with the parents of the school children or the citizens in general, for the warning was not heeded. A heavy outbreak occurred in 1752, and nearly 1,800 persons moved out of the town to escape its wrath.⁸ Immediately the question of inoculation was revived, and for a short time there was a hospital for this purpose on Noddle Island in Boston Harbor. But memory is short lived, and soon settlers flocked to Boston in such numbers that in the second decade of the 19th century (February 23, 1822) the town government had given way to a city form of government.

Shortly after this event we find the first official attempt to use the schools to overcome disease problems. In 1827, the school committee voted the first compulsory vaccination regulation for school children, which directed the master "to ascertain by probable evidence that every child who is offered for admission at school, shall have been secured against contagion of smallpox. And no child not so secured shall be received unless the school committee shall order such child to be received."⁹ The theme of this regulation is now found in some 16 state laws on vaccination.¹⁰

EARLY SCHOOL BUILDINGS

The early school buildings were simple structures, usually of wood, and devoid of architectural style. The interior arrangement of the school was vastly different from a modern building. The classroom was one large room with all classes assembled together. There were no blackboards, no maps, no pictures, nor were there window shades. There were neither extra rooms for recitation nor even special closet space for

clothes; these were later improvements.

The desks, with compartments for quills and books, were made of rough boards and the seats were without backs, so placed as to face the light. It was not until years later (about 1720) that an enterprising master concerned with the visual welfare of the scholars considered turning the benches around so that the light might come from behind. Then we waited a century and a half for the appearance of the commonly accepted "left hand" theory of light from the rear and over the left shoulder.

Garments and storm accessories were hung on tiers of hooks between the windows. The streams from the wet clothing ran along the floor and provided amusement for the scholars, and worry for the master, as the scholars tried to keep their feet above the water. The offensive schoolroom odor caused by the drenched clothing was a stormy-weather problem, particularly as there were as many as 100 to 200 pupils in each classroom.

There were neither bells nor radio to give the "No School" signal. Waterproof garments or rubber boots were unknown. The favorite foot protection was a pair of adult wool yarn, home-knit stockings drawn over the shoes.

The most important part of the school, at least during the summer season, so the scholars thought, was the old wooden pump. As it was generally located at the rear of the building, it was a familiar sight with its inviting dippers. Its constant use by the passing public created a problem for the masters. And in the period following the Revolutionary War we find in the records frequent complaints to the authorities as to "the evils arising from the free use of the pump, belonging to the schools."¹¹ This problem was solved by each pupil carrying his own drinking cup. On the final day of school it became customary for the

members of the last class in Latin School to celebrate their departure by kicking around their pails and cups until they were unfit for further use.

FIRST SCHOOL HEALTH SURVEY

The hygienic and sanitary conditions of school buildings did not receive any extensive consideration until the early part of the 19th century. In the year 1833 appeared the first survey of school conditions.¹² The school committee made a study and submitted recommendations concerning the physical properties of schools with reference to proper seating, heating, ventilation, and cleanliness. This report was unique for the times, as it stressed the relation of healthful and convenient places of instruction to mental success. The report of this survey with the suggested improvements was appropriately called "the charter of pupil welfare in public schools."

The beginning of the more modern type of seating began about 1842, following a petition of numerous parents, complaining of "the ever increasing prevalence of diseases of the spine among young females owing to the peculiar construction of the seats in which no support is provided for the back, and praying that an alteration of the seats may be made so as to remedy the evil complained of."¹³ This petition was followed by the further complaints that most of the desks were from 3 to 4 inches too low. The school committee corrected this evil by the purchase of a newer type seat and also prepared regulations as to the correct method of adjustment.¹⁴

Proper seating in relation to lighting came to the front after the Civil War. In 1876 the school committee originated and supervised the changing of desks and chairs for "left hand light" or to admit the light from the left of the scholars.¹⁵

The introduction of window curtains

"shades" in the latter 19th century was the first approach to the relationship of proper window lighting to visual health. Whether it was for economy or other reasons is not gleaned from the records, but window curtains were first installed in 1887 only on the southwest side of school buildings.¹⁶ The health value of proper window curtains is attested to by all educators today.

The first artificial light was gas, introduced in 1870 "into those rooms in school buildings which are not suitably lighted."¹⁷ However, gas was not generally used in the classroom to supplement the natural light. Its use was confined chiefly to dark hallways and basements.

The introduction of electricity in 1891, marked the beginning of artificial light to supplement daylight in the classrooms.¹⁸ The growing emphasis placed on the visual welfare of the pupil, the use of the school building as a civic center, thus necessitating lighting for evening sessions, construction of schools among tall buildings cutting off the unobstructed sky, thus making the natural light inadequate at many times, are the reasons why artificial lighting has become an essential part of the modern school building.

HEATING AND VENTILATION

Heating and ventilation soon followed the seating phase of this first survey. In the evolution of heating systems from fireplace to oil burner there have been many changes.

The school fireplace gave way generally to the Franklin stove after the Revolutionary War. This stove was invented in 1744 by Dr. Benjamin Franklin for burning wood, in which he introduced the principle of heating the air by means of a double or hollow back. It was in the form of an oblong box with the front removed. The smoke escaped over the top of this flat chamber, and passed downward be-

tween it and the real back of the stove, and then into the chimney. This hollow chamber communicated underneath the stove with a tube opening into the external atmosphere, and a quantity of air thus passed through the flat chamber and into the room through small holes left in the sides. Here appears the first attempt to construct economical stoves combined with the principle of sanitary heating and air supply to enclosed rooms.¹⁹

Furnace heat was generally introduced at the turn of the 19th century. The hot-air-furnace system was the first to emerge from the era of closed stoves.²⁰ It was not until after the Civil War that steam heat was commonly introduced.²¹ As early as 1846 there were printed rules and regulations "relative to the use of stoves, furnaces, and ventiducts in grammar schools."²² Later in the same year the school committee considered the subject of ventilation of school houses. The outcome was an experiment in three buildings with "such apparatus as may be required to secure proper ventilation in winter and summer and make such alterations and arrangements of the furnace as may be required."²³ This experiment was really the beginning of modern ventilation in school buildings.

That the school committee considered this heating and ventilation problem serious may be gathered from the happenings of the next year. In 1847 the committee conferred with the architects and builders on all new school buildings. In addition a report was forwarded to the mayor, aldermen and council demanding that the suggestion of the school committee concerning heating and ventilation be adopted. This report to the city officials was followed by a special order to the masters and teachers containing very definite rules on ventilation.

Again in 1862 the question of ventilation "without draft or current of

air" came to the front.²⁴ Then followed Robinson's and Main's systems which employed portable window ventilators, and they enjoyed popularity for some years. In 1886 the school committee on its own initiative supplied ventilating window boards on all windows of school rooms. At this period also, all radiators were guarded by screens. The first radical departure from the open window system was the Eureka ventilators, first installed in 1887. From then to the present day the field of school ventilation has seen many systems. In the last half-century, since the memorable report of the city architect in 1891 on all heating and ventilating systems, which listed those which fulfilled the requirements of statute, we have seen a gradual departure from the natural methods utilizing windows, doors, old-fashioned shafts in the walls connecting with the attic, and small apertures through the external walls of the classrooms to the modern varied modifications of the mechanical systems. In the recently constructed school buildings the school ventilating engineer has found most feasible a combination of direct radiation and mechanical means utilizing the unit ventilator.

To aid the teacher to participate better in classroom hygiene, thermometers were generally placed in the classrooms in 1885.²⁵ This device has served to make a more uniform temperature in the classrooms and to enable the teacher to keep the acceptable standard of "as near sixty degrees Fahrenheit to sixty-seven degrees Fahrenheit as possible."²⁶

SANITATION OF SCHOOL BUILDINGS

Sanitation of school buildings forged to the front toward the close of the 19th century. This interest closely paralleled the movement for preventive sanitation in the field of public health which included the period from 1885

to 1910. This interest in preventive sanitation prompted the law passed in 1888 relative to "sanitary provisions and proper ventilation in school houses." This law was the aftermath of two surveys, carried on independently by the Boston Board of Health under Dr. S. H. Durgin, and the Massachusetts State Sanitary Police under R. F. Wade, complaining of the unsanitary conditions and also the poor ventilation of most school buildings.²⁷ The following year a special appropriation of \$50,000 was made for sanitary improvements of all school houses.

Elimination of nuisances near school houses was the first extraneous problem. Stables alongside one school, and a house that was a contagious-disease problem nearby to a second, were some of the nuisances corrected. The early school sanitary problems were concerned mainly with outbuildings. The old-fashioned vaults of outbuildings demanded that the cess-pools be cleaned during the summer vacation. In 1889 there was a replacement by water vaults. With the innovation of the water vaults, a few schools experimented with the toilet facilities in the basement of the school buildings. However, when the Board of Health, in a survey of 1889, objected to this procedure on the ground of poor ventilation of toilets, it was halted temporarily. In the same year the old wooden urinals were replaced by stone and glass with the urinals partitioned off. Considerable attention was also given to the ventilation of the water-closets.

Shortly after, with the appearance of improved facilities, toilets were gradually introduced into the basements of the newer buildings. This gradual transfer of toilet facilities has continued until today no school building has facilities outside the protection of the main building. The modern plumbing improvements (fountains, etc.) make the school buildings of today a

decided improvement over those of two centuries ago.

Until the opening of the Cochituate water line, most schools depended for their water supply on nearby wells. However, after 1848 when the Cochituate water was brought to Boston the schools were generally piped for water.²⁸ Water filters were the first experiments connected with this improvement. Today sanitary bubblers are found in all buildings. Hot and cold water satisfy the handwashing needs of the pupils.

SCHOOL MEDICAL PROBLEMS

Toward the end of the 19th century the school committee, realizing the tremendous importance of school-health problems, considered creating the office of medical inspector of schools to supervise all matters pertaining to sanitary conditions, including measures for prevention of the dissemination of contagious diseases. However, the city solicitor ruled in 1876 that the school committee could not spend funds for that purpose.²⁹

Four years later, in 1880, the school committee again attempted to solve this problem by creating the office of instructor in hygiene. Again the city solicitor ruled against his performing the duties of medical inspector, although he could legally instruct in the normal and high schools.

Undaunted, the committee continued to urge this type of position. Finally, the office of instructor in hygiene was legally established in 1885 and continued until 1890.³⁰

An interesting contrast in the methods of handling school epidemics in the 19th and 20th centuries is seen in one of the early decisions of the instructor in hygiene. Owing to the prevalence of scarlet fever among the pupils of one of the primary schools, the school committee closed the building from January 22 to February 1, 1886, on advice of the instructor in hygiene.³¹ This is the

first instance of official closing of school due to an epidemic.

Another example of the school committee's attitude toward safeguarding the welfare of the pupils, and particularly the precautions taken against the spread of contagious diseases, was given in 1881. A house in which contagious diseases had spread was in proximity to a primary school building. The committee, considering it to be a nuisance and a menace to the pupils, allotted funds to buy a vacant lot nearby. The house was moved and the menace also, as well as allowing the school a better exposure to sunlight.

The well founded belief that the school furnished a medium for the spread of contagious diseases, especially diphtheria and scarlet fever, prompted the Board of Health, in 1887, to advise the school committee to provide for the frequent fumigation of the school houses throughout the city, in order to assist in preventing the spread of contagious diseases.

It was not uncommon for the Board of Health to issue the rule that "all the public school houses in the city be fumigated as often as once in each 2 weeks during the cold season; the work to be done by the janitor on Saturday burning 2 pounds of sulphur to each 1,000 cubic feet of space."³²

In 1894 the first organized system of medical inspection of schools was established by the Board of Health, which had at that time full jurisdiction over school health problems. Eighty physicians were assigned to visit daily the assigned schools.³³

Boston was again the leader in handling school health problems by establishing the position of director of school hygiene in 1907.³⁴ The physical and hygienic activities of the system were merged into one department. In

1912 women physicians were added to examine girls.³⁵ In 1915 the school physician and medical problems were detached from the Board of Health and assigned to this department under the school committee.³⁶ This department under the supervision of the school committee still continues to supervise the physical welfare of 140,000 pupils.

Sanitary Survey of Beverage Establishments

With Reference to Sanitary Condition of Glassware*

W. L. MALLMANN, PH.D., F.A.P.H.A., AND E. D. DEVEREUX, PH.D.

*Department of Bacteriology and Hygiene, Michigan State College,
East Lansing, Mich.*

SINCE the repeal of prohibition, there have sprung into existence numerous road-houses, taverns, saloons, and miscellaneous establishments for the dispensing of alcoholic beverages. To an alarming extent, these establishments are inadequately equipped to clean and sterilize the glassware used. Furthermore, there is a deplorable lack of information as to methods of cleaning and sterilizing and a surprising array of hurriedly concocted compounds purporting to be disinfectants on the market.

To determine how effectively beverage glasses were being cleaned and sterilized, a survey was conducted in Lansing with the coöperation of the local department of health. Several months prior to this study, the City Council had passed an ordinance requiring the use of chlorine sterilizers and specifically stated that rinse waters must contain 200 p.p.m. of available chlorine. No attempt had been made to see whether these regulations were being obeyed. A preliminary survey showed that few places were even attempting proper care in the handling of glassware, and in most of these the chlorine sterilizers were being grossly misused. Few places in the entire city had satisfactory glass-

ware. Many were not even provided with running water at the dispensing bar. Some were merely dipping the glasses in a pail of water which was changed at infrequent intervals. In a few, wash sinks were located in back-rooms inaccessible to the bar. Appearance of the bar and the wash sinks showed plainly that even rinsing the glasses in water was a rare occurrence.

EXPERIMENTAL

To determine the efficiency of the cleaning and sterilizing processes for glasses in the various establishments, it was thought necessary to examine: (1) the rims of clean and used glasses for the presence of bacteria; (2) the chlorine rinse water, the preliminary water rinse, and the cooling water for bacterial content; and (3) the chlorine rinse water for the presence of available chlorine. To obtain accurate bacterial counts of the chlorine rinse water, all samples were collected in sterile sample bottles to which had been added sodium thiosulphate as recommended by Mallmann and Cary.¹ Prior to sterilization each clean dry bottle received approximately 0.1 gm. of powdered sodium thiosulphate. The bottles were then sterilized in a hot air oven at a temperature not to exceed

* Journal Article No. 218 (M.S.) from the Michigan Agricultural Experiment Station.

200° C. In collecting the samples, care was taken not to rinse the bottles in the solution to be collected, in order to avoid any loss of the sodium thiosulphate. All rinse and cooling waters not containing chlorine were collected in the usual water sample bottle. All samples were rushed to the laboratory and tested immediately after delivery.

Chlorine residuals were determined by the orthotolidine method, using a Wallace & Tiernan Hellige comparator. Readings were made at the end of 10 minutes for the inorganic chlorine compounds, and 30 minutes for the organic chlorine sterilizers.

The bacterial counts of the rims of the glasses was obtained by swabbing. The swabs were placed individually in test tubes containing 0.75 c.c. of sterile saline solution. Both clean and used glasses were tested by swabbing the rims on the inside and outside, to a depth of approximately $\frac{3}{4}$ inch. Swabs were washed off in 3 c.c. of sterile saline solution, and agar plates made using appropriate dilutions. The remainder of the swabs were smeared on blood agar plates. All plates were incubated at 37° C. for 48 hours when total counts were made. The blood agar plates were examined for the presence of streptococci.

To present the bacteriological picture found in the various establishments examined, typical reports of each significant type are reported.

In Report No. 1 is presented a fairly typical picture of a beer garden in which the glasses were rinsed in a tank of water supposedly containing a chlorine disinfectant, but which failed to show any chlorine at the time of examination. The proprietor conscientiously rinsed the glasses in the supposedly chlorine rinse water and then drained them inverted on a rack prior to use. The failure to sterilize the glasses properly was due to the preparation used. The clean glasses showed

an average of 50,000 bacteria per rim while the chlorine rinse water contained 6,000 bacteria per c.c. The number of bacteria on the used glasses was far below that of the clean glasses. This would be expected as the bacteria are washed off into the beverage in the glass. Although the total number of bacteria on the used glasses was low as compared to the number on the clean ones, still 3 of the 5 used glasses examined showed streptococci. This beer garden, although the proprietor

believed that he was sterilizing his glasses, typifies the condition wherein the glasses are rinsed in a tank or pail of water which is infrequently changed. Such cases are extremely common, particularly in cities having no ordinances requiring the use of sterilizing agents. In several instances the writers have observed glasses being refilled without cleaning of any nature. In such places it is a question which procedure is worse, washing in dirty water or refilling the glasses without rinsing.

In Report No. 2 is presented a typical case of a popular (heavily patronized) beer garden where a large number of glasses are used. In this establishment, care was exercised by the bartender to maintain a residual chlorine content in

the rinse water. At the time of examination, 18 p.p.m. available chlorine were found. The sterilizer in use was an organic chlorine preparation. The glasses were rinsed for only a few seconds and immediately filled and returned to the patrons. An examination of 5 clean glasses revealed an average bacterial count of 17,000 per rim. The rinse water, although it contained a chlorine residual of 18 p.p.m. contained 36,800 bacteria per c.c. Although the amount of active chlorine should have been sufficient to destroy the bacteria introduced, the activity of the chlorine in this type of compound (organic chlorine) was too slow to destroy them as fast as they were added by the glasses. The result was an accumulation of bacteria that recontaminated the glasses. If the glasses had been inverted and allowed to drain for 5 to 10 minutes the chlorine on the glass

lishment the glasses were first rinsed in tap water, then in the chlorine solution, and after varying periods of draining were immersed in a tank of ice water to cool them prior to filling. At the time of inspection the chlorine tank contained only 7.5 p.p.m. available chlorine. The glasses examined had not been immersed in the cooling tank. Five glasses showed an average count of 16,200 bacteria per rim, though 2 of the 5 were sterile. The chlorine rinse water was sterile but no glasses were being rinsed at the time of inspection. The cooling water showed 22,800 bacteria per c.c. Even though the chlorine solution sterilized the glasses effectively, they were reinfected by immersion in the cooling water. The use of cooling tanks should be discouraged unless they have a constant flow of fresh water passing through them.

In a few instances (Reports 4 and 5) fairly satisfactory procedures were in use. Organic sterilizers were used and although the chlorine residuals were low, 4 to 7.5 p.p.m., the exposure was sufficiently long to lower the counts per glass rim to negligible numbers. The glasses were allowed to drain for 5 to 10

minutes after chlorination. Prior to chlorination they were thoroughly rinsed in either tap water in a tank or running tap water to remove any beer, which is necessary if efficient chlorination is to

be expected. Obviously running tap water is the better of the two rinses. In one of the establishments the glasses were rinsed again in tap water prior to filling.

The occurrence of high bacterial counts in rinse water containing chlorine

was coincident with the use of organic chlorine preparations. The delayed action of organic chlorine compounds has been demonstrated by Mallmann and Cary¹ in the case of water disinfection, and in dairy equipment sterilization by Devereux and Mallmann.² In the latter work varying concentration of both types of chlorine sterilizers were passed through dairy equipment. The partially spent chlorine solutions were recovered and found to have a high residual chlorine content though considerably less than the fresh solution used. The writers were interested in knowing the comparative values of these solutions after the available chlorine had been partially destroyed. Five hundred c.c. samples were inoculated with suitable numbers of *Escherichia coli* and transplants were made to nutrient broth at the end of 15, 30, 45, 60, 90, 120, and 180 seconds. The broth was used as a dechlorinating agent, and subsequently all the tubes were plated to determine the number of surviving bacteria for each period of exposure. The data are presented in Table I which is a rearrangement of the data that appeared in Table III of that report. In the case of the inorganic chlorine compound sterilization was effected in 15 seconds with chlorine residuals of 40 and 81 p.p.m. and in 45 seconds with 17 p.p.m. available chlorine. On the other hand, the organic chlorine prepa-

ration was comparatively extremely low. It took 180 seconds to sterilize with 76 p.p.m. and no sterilization was effected with either 36 or 60 p.p.m. in the same time. The organic chlorine sterilizer used in these experiments was the same compound encountered in the beer gardens. These data show that the delayed activity of organic sterilizers is the same in partially spent solution as in freshly prepared solutions. The delayed activity does not necessarily condemn these compounds because they have certain properties that are quite desirable, but it means that longer exposures must be used to obtain the same results that can be obtained with the inorganic chlorine sterilizers.

To obtain some idea of the time necessary for beverage glass disinfection with both organic and inorganic chlorine sterilizers, extreme pollution conditions were set up in the laboratory. Typical test organisms representing both Gram-positive and Gram-negative organisms were used. As *Staphylococcus aureus*

has a resistance equal to or greater than most of the Gram-positive pathogenic cocci, this organism was selected. *Escherichia-coli* was selected as a typical representative of the Gram-negative organisms. Suspensions of 24 hour cultures were made using the growth from 3 to 4 well covered agar slants to 100 c.c. sterile salt solution. Clean slides were dipped into these suspensions, immersing one-half of each slide, draining and drying in air.

Seven slides were prepared for each experiment with each organism. Two slides (Nos. 3 and 4) were immersed without agitation in 100 c.c. of a chlorine sterilizer for 20 seconds when they were immediately transferred to a deep culture dish containing 25 c.c. of sterile sodium thiosulphate (approx. 0.5 per cent) water. The slide was agitated for 10 seconds rapidly to free the slide of any viable organisms that remained after chlorination. Subsequently the final rinse water was plated to determine the number of bacteria

surviving. The sodium thiosulphate in the water neutralized any chlorine that might have been carried over on the slide and prevented further bacterial action. The minimum of 20 seconds was selected because in previous trials it was found that sterility was not obtained with inorganic sterilizers in less time. Slides Nos. 5 and 6 were treated in a similar manner except that exposure in the chlorine solution was for 60 seconds. To check the number of bacteria actually killed by the chlorine, 3 control slides (1, 2 and 7) were tested. Slide No. 1 was immersed in 100 c.c. of sterile water for 20 seconds to simulate the washing that resulted in immersing the slide in the chlorine water bath; then transferred to 25 c.c. sterile water; agitated rapidly for 10 seconds; and agar plates made from this rinse to determine the number of bacteria present. Slide No. 2 was treated in a similar manner except that it was held in the first water bath for 60 seconds. Slide No. 7 was agitated rapidly in 100 c.c. sterile water to remove all of the viable organisms that had been removed in the experiments in the 100 c.c. of chlorine sterilizer and subsequently in the 25 c.c. of water used for the final rinsing of the slide. The chlorine sterilizer was used in concentrations of approximately 200 p.p.m. available chlorine.

Several trials were conducted with both organisms using an inorganic and organic chlorine compound. The results of representative experiments are given in Table II, and show that even with 500,000 to 1,000,000 *Staphylococcus aureus* on an area of 3 sq. in., an inorganic chlorine preparation can effect complete sterilization in 60 seconds. If this large number of *Staphylococcus aureus* can be killed in this time, surely streptococci and other pathogens that are more susceptible to disinfectants and which occur in far smaller numbers on the rims of used glasses can be de-

stroyed. *Escherichia coli* is much more susceptible than *Staphylococcus aureus*, which is to be expected from previous observations on the comparative resistance of these two organisms. Although the organic chlorine compound was able to kill *Escherichia coli* in 60 seconds it failed in the case of *Staphylococcus aureus*. This means that a longer exposure must be used where this compound is used. It would seem on the basis of these data that, in routine sterilization of beverage glasses, a period of exposure of 5 minutes should be required.

DISCUSSION

The fact that many of the establishments dispensing beverages in glasses were not provided with adequate facilities for the effective cleansing and sterilizing of their glassware, and that in many places having adequate equipment and materials, these were not properly applied, demonstrates the need of the development of proper methods of treatment and an educational and regulatory program whereby proper cleansing and sterilization can be assured. It seems needless to point out the dangers of disease transmission by the use of improperly sterilized glasses, since all sanitarians are cognizant of them.

To determine how effective an educational and regulatory program could be made, a plan was formulated. First, on the basis of the experimental work presented the following regulations for the care of beverage glasses were prepared.

1. *Provide rinse to remove material from glass.*—In many places where chlorine rinses were in use, the bartenders were rinsing the beer laden glasses directly in the chlorine water. The organic matter introduced from the beer soon destroyed all available chlorine and the rinse, instead of acting as a sterilizing agent, functioned as an

inoculating bath to give each glass rinsed a composite contamination. In all cases, the glasses should be cleaned before they are immersed in the chlorine water. The amount of cleaning will depend largely on the physical appearance of the used glasses. In places where only beer is dispensed, this cleaning may consist in merely rinsing the glasses in running tap water. The use of still water unless changed frequently should be discouraged.

2. *Provide a tank of chlorine rinse water containing when freshly prepared 200 p.p.m. chlorine and at no time less than 100 p.p.m. This rinse must be changed at least once a day, and oftener if the volume of glassware disinfected reduces the chlorine below the minimum limit.*—The writers have previously observed that any amount of chlorine in excess of the chlorine demand of the water is practically as effective as large excesses, but solutions containing minimum amounts of chlorine have little or no reserve powers. Where a rinse solution is used repeatedly, as under the conditions cited, the reserve chlorine content of the solution when freshly prepared should be as high as the hands can stand without injury. Two hundred p.p.m. is not injurious. A minimum of 100 p.p.m. was established not because concentrations below this figure were considered ineffective, but because it gave the inspector a better opportunity to force the proprietors into a more strict adherence to proper sterilization.

3. *Leave glasses immersed in the chlorine rinse for at least 5 minutes, or immerse and then allow glasses to drain for 5 minutes inverted on a rack without rinsing off the chlorine water.*—This period of exposure gives at least 2 to 3 minutes' safety factor even with organic chlorine preparations and assures sterile glasses. Possibly an exposure of 2 to 3 minutes would be ample, but in the hands of the

average individual the longer period is advisable.

4. *Glasses after draining for at least 5 minutes or being immersed 5 minutes in the chlorine rinse may be placed in running tap water to cool, preparatory to filling with beer or other beverages.*—Preferably glasses should be filled without rinsing off the residual chlorine, but in the case of heavy mugs and glasses it is necessary to cool the glass prior to filling. The use of a tank filled with ice is not recommended, due to the danger of bacteria accumulating and recontaminating the glasses.

5. *All glass disinfectants must receive the endorsement of your department of health before they can be used. Failure to comply will be considered a violation of this code.*—This provision prevents high pressure sales of spurious products such as are flooding the market at present. Since this code was adopted in Lansing a number of such products have been tested and rejected as unsatisfactory.

6. *All glass disinfectants must be of such a nature that the sanitary inspector can by means of a simple test determine the amount of said disinfectant in the rinse water.*—A check on the rinse water is the only convenient test that can be made to insure proper sterilization. There are compounds on the market that will sterilize, but there is no convenient procedure for checking their presence quantitatively, so the inspector must rely on the statement of the proprietors that a disinfectant is being used, and this is highly unsatisfactory. An orthotolidine test for chlorine is easily made and the results furnish dependable evidence, particularly if prosecution is necessary.

At the time this code was put in operation the proprietors of all establishments were requested to attend a meeting for instructions. An attempt was made to impress them with the need of effective sterilization and to

teach them proper methods. It was hoped that an educational program would make them appreciate the fact that the department of health was attempting to assist them, rather than to force the observation of regulations that may have seemed unjustified.

The result of this program has been exceedingly gratifying. After 2 months without any extensive prosecutions, only one establishment was found that was not carrying out the regulations. The proprietor was an uneducated man who had not attended the school of instruction.

SUMMARY

Reports are given showing the common

methods used by taverns for cleaning and sterilizing glassware, few being satisfactory. Excessive numbers of bacteria were found on most of the glassware.

The ability of chlorine sterilizers to kill these organisms was demonstrated. The sterilizers were applied at room temperature in order to duplicate practical conditions, in which the inorganic compounds were more efficient.

Recommendations are given for the proper cleansing and sterilizing of glassware for establishments dispensing beverages.

Scarlet Fever

“ . . . From the above considerations I would suggest that:

1. The term “scarlet fever” be abolished. I have endeavored to show that scarlet fever is an infection by the hemolytic streptococcus not differing from other hemolytic streptococcal infections in any matter of practical importance. But in practice it is found that the retention of the term “scarlet” concentrates attention on what may be the most obvious, but is in reality the less important feature of the disease, namely the rash. I would suggest the term “Hemolytic fevers” be adopted to cover the whole group.

2. It follows that notification should be Hemolytic Fever, not Scarlet Fever. To notify only the cases showing a rash like the textbook description of a scarlet fever rash, is to notify only a part of the epidemic, and on the whole,

experience in Chelmsford suggests that it is the least important part.

3. The use of the isolation hospitals should be restricted to two classes of cases only.

(a) Cases suffering from hemolytic streptococcus infection who are so seriously ill, or in such poor home surroundings, as to make hospital necessary for *treatment*, quite apart from isolation.

(b) Cases suffering from hemolytic streptococcus who, by reason of their home conditions, require to be isolated as being a danger to the community. Such cases as dairymen, people living in hotels, lodging-houses, etc., would come under this category.”—Sleigh, J. C., M.B., Ch.B., D.P.H. (Medical Officer of Health, Chelmsford), Scarlet Fever. *J. Roy. San. Inst.*, June, 1935, p. 662.

Rocky Mountain Spotted Fever in New York State Outside of New York City

E. R. MAILLARD AND E. L. HAZEN

*Division of Laboratories and Research, New York State Department of Health,
Branch Laboratory, New York, N. Y.*

IN view of the scarcity in the literature of reports of Rocky Mountain spotted fever in the eastern section of the United States, it seemed of interest to submit a brief summary of 10 cases presenting clinical evidence of Rocky Mountain spotted fever which have occurred in New York State (outside of New York City) from 1926 to 1934, and to record the results of the agglutination tests performed with *B. proticus* X 19 with blood specimens from the patients.

The 10 patients, 2 of whom were members of the same family, were residents of rural districts in one county on Long Island. The patient referred to in the report of Gilbert and Coleman¹ also lived in the same county. Four of the 10 patients were children whose ages ranged from 2½ to 6 years, and 6 were adults whose ages were from 20 to 52 years. There was an equal distribution of the cases between the sexes. All of the patients became ill either in the late spring or in the summer. Nine of the 10 persons had been in contact with ticks, 5 of whom reported that they had been bitten only a short time before the onset of illness. The remaining patient was a farm laborer whose surroundings and living conditions were fairly good and did not suggest rat infestation. However, he might easily have come in contact with ticks while working in the fields.

The clinical symptoms recorded on the histories accompanying blood specimens received from the patients were such as have been described by Rumreich² for Rocky Mountain spotted fever. The symptoms may be summarized as follows: The onset was sudden. The patients complained of severe headache, marked prostration, loss of appetite, constipation, and fever. The rash appeared early in the disease, first on the extremities, later becoming generalized. This eruption in the initial stages was macular and erythematous in appearance but upon extension became papular and petechial, and in some instances there was a coalescence of the petechiae forming larger hemorrhagic areas which persisted for several weeks. The peak of the temperature in the majority of the cases was 104° F., and in a few it reached 105° F. Nervousness, restlessness, and lethargy were common, and delirium was not unusual. Several of the cases showed rigidity of the neck and back and a few showed paralysis of the extremities. There was slight impairment of sight and hearing in a few instances. The disease was of several weeks' duration and the mortality rate was 30 per cent.

The strain of *B. proticus* X 19 (No. 211) employed in the agglutination test was obtained from Dr. Mooser of Mexico City. An alcohol-treated suspension³ of the microorganisms was em-

ployed, the opacity of which was equal to that of the barium-sulphate standard No. 3.⁴ Such a suspension was employed in every case but one in which a living culture of *B. proteus* X 19 strain No. 211 was used. From one to three blood specimens from each patient were examined, and wherever possible the agglutination test was also carried out with the serum heated for $\frac{1}{2}$ hr. at 56, 60, and 65° C. The tests were read after an incubation period of 2 hours at 45° C., followed by from 16 to 18 hours in the refrigerator. The results of the tests are given in Table I.

SUMMARY AND CONCLUSION

A marked agglutination reaction was demonstrated with *B. proteus* X 19 in the blood sera from 8 of the 10 patients, and partial agglutination was obtained with two of the sera. The latter two specimens were collected very early in the disease as the patients died on the 10th and 11th day, respectively, of their illness. Although no conclusions can be drawn from the few cases studied, the importance of obtaining a series of blood specimens from suspected Rocky Mountain spotted fever cases is indicated. Davis, Parker, and Walker⁵ have recently suggested that three samples of blood should be taken, the first one as soon as spotted fever is suspected, the second during the period from the 10th day to cessation of fever,

and the third at about the end of the first week of convalescence.

The epidemiological and clinical data in this series of cases suggested that the disease was Rocky mountain spotted fever. In 9 of the 10 cases there was either clinical evidence of tick bite or a definite history of contact with ticks before the onset of illness. None of the cases could be associated with flea bites. The distribution and character of the rash in the majority of the cases were strikingly similar, appearing early on the extremities, later becoming generalized. The cases occurred from 1926 to 1934, in the late spring and summer of successive years for the most part, and only in rural localities of the same county; in one instance two members of the same family were infected. There was a mortality rate of 30 per cent in this group of cases.

Relative Value of Heated Toxin and Toxoid as Controls in the Schick Test

ELLEN LOEFFEL, M.D., AND EDWARD MASSIE, M.D.

*Department of Pediatrics, Washington University School of Medicine,
St. Louis, Mo.*

BECAUSE of the tendency of many adults and certain older children to show nonspecific pseudo reactions with the Schick test, it has been the common practice to use on such persons an additional injection of the test-toxin heated to 75° C. for 5 minutes as a control. This heating destroys the thermo-labile toxin, and any reaction in the control test is considered as a skin sensitivity to substances in the test material other than diphtheria toxin. Persons who react to the control test are read as "negative pseudo" or "combined positive," depending on the comparison of the degree of the reaction produced by the test and the control.

It was soon discovered that "combined positive" reactors, or those who gave positive Schick tests and some reaction also in the control, often tended to show severe local disability and also general toxic reaction when later injections of toxin-antitoxin or toxoid were given. This led Moloney and Fraser¹ to suggest that such susceptibility to the immunizing injections might be more readily determined by using a test of diluted toxoid (1:20) as control, since such a test would serve also as a control for the Schick test.

Since the diluted toxoid obviously contains much more of the nonspecific skin reactive substance than the heated

toxin, it is to be expected that it would reveal more readily those persons sensitive to later immunizing antigen injections. On the other hand, while the pseudo reaction reaches its maximum development in 48 hours and has usually faded by the 4th day when the Schick test is read, a very marked pseudo reaction may persist as long as 4 days. Therefore, the toxoid skin reaction in certain instances might be expected to be so intense as to interfere with the interpretation of the Schick test, that is, it might be difficult to distinguish a negative-pseudo reaction from a combined positive, even as late as the 4th day.

This paper gives the results of a series of tests with Schick toxin, heated toxin control, and toxoid 1:20, in an attempt to determine:

1. Whether the diluted toxoid control contains the nonspecific skin-reactive substance in a concentration so high that the resulting pseudo reaction will confuse the reading of the Schick test.

2. Whether positive tests with both the heated toxin and diluted toxoid indicate that the individual will have a general reaction after injection of toxoid for active immunization.

METHODS

Intradermal injections of Schick test toxin, heated toxin control, and diluted toxoid control were carried out on each

TABLE I

COMPARISON OF REACTIONS WITH HEATED TOXIN AND TOXOID SCHICK TEST
CONTROLS—48 HOURS

	Number of Cases	Heated Toxin Control				Diluted Toxoid Control			
		++	+	±	—	++	+	±	—
Schick Positive	20	1	1	3	15	14	3	3	0
Schick Negative	40	4	3	1	32	26	11	3	0
Totals	60	5	4	4	47	40	14	6	0

of 161 unselected white and colored subjects of both sexes whose ages ranged from 8 to 65 years. The majority of subjects were young to middle-aged white adults. The test group included patients from hospital wards, as well as nurses and medical students. No attempt has been made to differentiate results on the basis of age, sex, or color. The material used was furnished by Ely Lilly and Co., Indianapolis.

Since pseudo reactions reach their height on the 2nd day, all readings were made on the 2nd as well as the 4th and 7th days. Those reactions which measured 20 mm. or more in diameter were called "++"; those between 10 mm. and 20 mm., "+"; while those that showed an area of reaction of more than 5 mm. but less than 10 mm. were called "±." For practical purposes in tabulating results, all ± reactions are considered as negative.

Of the 161 persons tested, 60 had some reaction in one or both controls, and this group formed the basis of the

study. One-third of these were read as "combined positive" and the remainder proved to be "negative pseudo" reactions. The other tests were frank positive (35) or negative (66).

RESULTS

Second day readings—In Table I are summarized the results of the control test readings at the end of 48 hours, and the differences in size and number of reactions produced by the heated toxin and diluted toxoid. It will be seen that with the toxoid control a total of 54, or 90 per cent of the subjects, showed reactions which were more than 10 mm. in size (++ or +) whereas only 9, or 15 per cent, of them showed positive readings with the heated toxin control. Similarly, 40, or two-thirds of the toxoid reactions were larger than 20 mm., while only one-twelfth of the heated toxin tests were of this size.

Fourth day readings—In Table II

TABLE II

COMPARISON OF REACTIONS WITH HEATED TOXIN AND TOXOID SCHICK TEST
CONTROLS—4 DAYS

	Number of Cases	Heated Toxin Control				Diluted Toxoid Control			
		++	+	±	—	++	+	±	—
Schick Positive									
Reading ++	8	0	0	1	7	4	1	1	4
Reading +	12	0	0	1	11	5	1	2	2
Totals	20	0	0	2	18	9	3	2	6
Schick Negative	40	0	4	0	36	9	12	2	17

are shown the results of the same control tests at the end of 4 days—the usual time for reading Schick tests. Here the differences between the reactions of the heated toxin and the toxoid are quite apparent.

It will be seen that whereas a positive reaction is still present with the toxoid control in 33, or 55 per cent, of the 60 cases, there remains a positive reading with the heated toxin in only 4, or 7 per cent, of the subjects. Readings obtained on this day emphasize the importance of the use of a control with the Schick test as well as the advantage of the heated toxin for use as this control. Of the 40 Schick negative readings obtained on the 4th day, 4, or 10 per cent, would have been considered positive if heated toxin had not been used as a control, since the size of the pseudo reaction was sufficiently large to be misleading. Further analysis demonstrates that 12 of the Schick tests which are considered positive with reference to the heated toxin control would be read negative if only

the diluted toxoid control were used. Thus the toxoid control would have caused an erroneous negative reading in 12, or 60 per cent, of the 20 positive Schick tests.

Table III gives the detailed reactions in 4 selected cases and further emphasizes the difference in Schick test readings with reference to the 2 controls since all of these errors of reading the test are apparent.

Seventh day readings—Since Schick tests remain positive for some time and the pseudo reactions fade more quickly, it has been stated that any confusion caused by pseudo reactors would be obviated if the final Schick test readings were delayed until the 7th day.

In Table IV are shown these 7th day readings. It is apparent that the reactions of the diluted toxoid control may be present to a sufficient extent on the 7th day to cause an erroneous reading. This is true in 12, or 60 per cent, of the 20 positive tests. The use of the heated toxin as a control eliminated this error in interpretation of the test.

TABLE III

FOUR EXAMPLES ILLUSTRATING POSSIBLE ERROR IN READING SCHICK TEST USING TOXOID AS CONTROL

	Size of Skin Reaction in mm.			Schick Test Reading Using Only Heated Toxin Control	Schick Test Reading Using Only Diluted Toxoid Control

Reactions following toxoid injections

—In the group of adults with positive Schick tests, 24 were given an injection of 0.5 c.c. of alum precipitated toxoid subcutaneously. Twenty of these had shown no skin reaction in 48 hours to either the heated toxin or the toxoid control. None of these had any general toxic reaction after the injection although many had a local redness and soreness of varying degree at the point of injection. The other 4 had all shown positive tests in the toxoid control of the 2nd day, and all developed a severe generalized reaction following the toxoid injection. This consisted of intense headache, fever, chills, and malaise lasting 2 to 5 days. Only 1 of the 4 (Case 1, Table III) had had any skin reaction to the heated toxin and this was less than 10 mm. in diameter, but the subject showed the most severe generalized reaction, although only 0.1 c.c. of the alum precipitated toxoid was given. The other 3 of whom Case 3, Table III is one, gave similar control skin tests, positive only with the diluted toxoid. One of them, in addition to the severe general reaction, developed a large sterile abscess at the site of injection. From this small group it would appear that there is insufficient "pseudo-reaction-substance" in the heated Schick toxin control to indicate susceptibility to general reac-

tion from toxoid injections; and also that the injection of alum precipitated toxoid is prone to produce very severe reactions in those persons who give positive skin tests to diluted toxoid.

DISCUSSION

Although the number of subjects studied is comparatively small, the relative value of the two types of Schick test controls seems clearly indicated. Heated toxin, preferably of the same lot used in the Schick test, is a proper control and apparently allows a correct interpretation of pseudo reactions in the Schick test. Diluted toxoid (1:20) on the other hand, is not a true control, and its use in certain instances obscures the reading of the test, since some Schick-positive persons will be interpreted as negative-pseudo reactors. However, the diluted toxoid skin test is superior to the heated toxin control as an indication of the subject's susceptibility or sensitivity to reactions following toxoid injections.

Because pseudo reactions are rare in infants and young children, and since at these ages severe reactions following immunizing injections are almost unknown, it has become customary to omit controls when Schick-testing them. With older children and adults pseudo reactions are much more common, and apparently the skin sensitivity pro-

ducing them is closely associated with the production of severe reactions to immunizing antigen injections.

When toxin-antitoxin was the commonly used antigen, any reactions following injections were usually mild apparently because of the small amount of reacting material present. When toxoid replaced toxin-antitoxin as immunizing antigen, the larger quantity of reacting material produced increasing numbers of severe reactions in susceptible persons. In the more recently used alum precipitated toxoid antigens, apparently the reaction-producing substance is precipitated as well as the toxoid, and their injection may produce severe reactions which are often incapacitating for several days. The indiscriminate use of such injections in older children and adults, therefore, is a matter of some importance, and if the use of a suitable skin test will warn of the danger of such severe reactions, such controls are well worth while. It is not yet certain just what measures are advisable to immunize such susceptible persons, whether toxin-antitoxin injections or small doses of unprecipitated toxoid. It is possible that some method of removing some or most of the offending material may eventually be discovered.

While the value of controls in older children and adults would therefore seem unquestioned, the use of two controls—one of heated toxin as a control for the test, and another for determining sensitivity to toxoid reactions—would be considered impractical by

many. It would seem that both these controls might be combined in one test by using a Schick test solution to which a small amount of toxoid (*e.g.*, 1:20) had been added to increase the amount of pseudo reaction substance present, and to use the same material heated to 75° C. for 5 minutes as a control. With such material, readings at 48 hours would indicate the pseudo reactors who might be expected to develop severe symptoms after toxoid injections and readings on the 4th to 7th day would determine which of these were "negative-pseudo" and which were "combined positive."

CONCLUSIONS

In performing Schick tests, a proper interpretation is possible only when a heated preparation of the same material employed for the test is used as a control. The use of diluted toxoid as a control interferes with the reading of the test by producing more marked pseudo reactions, but is therefore of great value in indicating those persons susceptible to toxic symptoms following immunizing injections of antigen. It is suggested that a more satisfactory Schick test material for older children and adults might consist of a mixture of toxin and toxoid.

Survival and Rate of Death of Intestinal Bacteria in Sea Water*

PAUL J. BEARD AND NIEL F. MEADOWCROFT

Laboratories of Sanitary Engineering and Bacteriology and Experimental Pathology, Stanford University, Calif.

THE classic reports of Jordan and his coworkers¹ in 1904 mark the real beginning of systematic studies of typhoid longevity under various natural conditions. Investigations confirming and extending those observations have been in progress more or less continuously from that time to the present date. The majority of the studies have been concerned with the length of the survival of the typhoid organisms in fresh waters of varying degrees of purity. With the development of devastating epidemics of oyster-borne typhoid in 1924-1925, considerable attention has been directed to the longevity of the intestinal group in salt waters and oyster liquors. Bulstrode and Klein² in 1896, Stiles³ 1912, and Round⁴ 1914, were among the early investigators who concerned themselves with the rôle of oysters in the transmission of water-borne disease, while Tonney and White⁵ 1925, Jordan⁶ 1925, Kinyoun⁷ 1925, and Krumwiede and Park⁸ 1926, present the more modern studies.

Of additional importance in directing attention to the viability of the intestinal pathogens in sea water has been the rapid tendency toward the development of beaches for recreational pur-

poses. The problem becomes, then, of acute interest to those municipalities discharging raw or partially treated wastes into oceans, bays and estuaries.

In spite of all the investigations, however, there remains a lack of definite quantitative data concerning the behavior of this group in polluted salt waters. de Giæxa⁹ 1889 seems to have been the first to attack the problem, and others have followed as cited. Approximations of survival time have been indicated, but technical difficulties have interfered with gaining more exact expressions. The possibilities of error in attempting to select a few typhoid colonies from among the many types developed from highly polluted waters even with the most selective media available and the best of technics are obvious.

The report by Wilson and Blair¹⁰ 1927 of a highly selective medium for typhoid isolation offered a possibility of adding to the information at hand upon typhoid survival and rates of death.

After some experimental work the technic of preparing and using the Wilson-Blair bismuth medium was standardized to the point where comparable colony counts of a Rawlings strain of *Eberthella typhosa* were obtained on this medium and routine nutrient agar. From a plate prepared from fresh stools of a typhoid patient 50 colonies selected as typhoid were

* Extract of thesis presented to Committee on Graduate Study in partial fulfillment for the Degree of Engineering.

confirmed on Russell's medium and 20 per cent of these selected at random were confirmed serologically. The data indicate sufficient reliability and selectivity for application of the medium to the study of rates of death.

METHODS

It was proposed to follow the procedure of Jordan¹ of immersing fluid cultures of the organism in cells or sacks of membranes permeable to water and at least some of the dissolved and colloidal substances that might be present in the waters under investigation. The construction of the cells is indicated in Figure I. The cells, essentially sideless brass flasks, were made of brass heavily coated with paraffine to prevent any oligodynamic phenomena. A brass plate, paraffine coated, and the permeable membrane covered the back and front of cells, respectively, and were held in position by the clamps indicated in the drawing. Rubber gaskets effectively prevented any leakage in or out of the cells.

The membranes were prepared by soaking filter paper in a solution of 2.5 per cent pyroxylin in glacial acetic acid. Tests showed the *Escherichia coli* was always restrained, but that after prolonged immersion some cultures of *Serratia marcescens* might to a slight extent come through; from which it was indicated that fair sized particles in polluted waters could pass into the cell. The organisms studied were a Rawlings strain of *Eberthella typhosa* and a laboratory strain of *Escherichia coli*.

The field of operation was San Fran-

cisco Bay at Palo Alto, California, into which the untreated sewage, chiefly domestic in type, of that city was discharged. Naturally the constituents of the water are subject to considerable variation. Table I shows the average of a number of analyses at various stages of the tide.

The cells were immersed in duplicate in the waters of the bay. The temperature of the bay waters during these experiments did not deviate greatly from 10° C. In one cell the suspending medium was fresh unfiltered water from the bay, in the other the same water sterilized by passage through an L 3 Chamberland candle.

At appropriate intervals the flasks were taken up, samples were withdrawn, and within 15 minutes were in the laboratory for plating.

A number of such experiments were performed. The general picture obtained was the same in all cases. For economy of space three typical sets of data only are included in Table II.

A number of similar experiments substituting *Escherichia coli* for *typhi* were carried out and one set of those data are presented in Table III.

The data obtained in these studies have been as consistent as could be expected in a situation where environment is not under control.

In all experiments the death rates

observed were quite consistent in their respective menstrooms. While the difference was not great, the rate of death was invariably higher in the unfiltered than in the filtered water. By the end of 24 hours this difference was very marked. However, by the end of the third day (72 hours), this difference had begun to be less pronounced. Possibly by this time organisms or substances destructive to the bacteria had undergone death or change.

Experiment 3 is at apparent variance with the other two cited. The data for the first 7 hours, however, were consistent; as a matter of fact those for the first 24 hours were not badly out of line. It is thought probable that leaks in the paraffine coating or filtered water cell may have occurred allowing contact with the metal with resultant oligodynamic death. Earlier test experiments not included here demonstrated this lethal effect. The behavior in the

* Membranes showing effects of exposure. Experiment discontinued.

companion cell a few inches away was consistent with other data. The experiment is included here because the survival time of 22 days is of interest.

The initial death rate of *Escherichia coli* in filtered and unfiltered sea water was quite comparable to that of *Eberthella typhosa*. After the first 7 hours, the destruction was much less rapid and the survival period indicated was much longer although this experiment could not be carried to its desired conclusion, by reason of the membrane destruction. The experiment indicates again the reliability of the species as an index of pollution in sea water as in fresh water.

SUMMARY

The experiments demonstrate the reliability and selectivity of the Wilson-Blair, bismuth-sulphite medium for typhoid isolation and quantitative studies in polluted water.

Data are presented showing rates of

death of *Eberthella typhosa* and *Escherichia coli* under closely simulated natural conditions in polluted sea water. The possibility of survival of both species over a period of at least 1 month is indicated.

Escherichia coli is shown to be sufficiently resistant to sea water to serve as an indicator of pollutional conditions in such an environment.

Control Agglutination Studies Against *B. Dysenteriae* on the Sera of 300 Individuals in New York City

JOSEPH FELSEN, M.D., AND A. G. OSOFSKY

Department of Laboratories and Research, The Bronx Hospital, New York, N. Y.

IN previous reports on outbreaks of Sonne-Duval dysentery¹ and atypical Flexner dysentery² the authors called attention to certain bizarre and unrecognized forms of the disease. Briefly, these were the asymptomatic, constipated, meningitic, and appendicular types. The asymptomatic type is diagnosed only in the course of epidemiological studies. The constipated type formed a well defined group which, paradoxically enough, were typical cases of bacillary dysentery from every other standpoint. The meningitic form occurred in children, was characterized by the usual clinical signs of meningitis, was accompanied by a labial or nasal herpes, but showed entirely negative spinal fluid findings. Subdural inoculations into rabbits in two cases did not reproduce the symptoms or any pathological lesions. The appendicular group was very striking, occurred chiefly in children, closely resembled acute appendicitis, but the operative findings in almost every case revealed a normal appendix, a mystifying mesenteric lymphadenitis and an acute inflammation of the terminal ileum. The detailed clinical and laboratory findings have been described elsewhere.³⁻⁴

The senior author has been privileged to examine more than 300 cases of dysentery in the New York City and

Jersey City areas within the past 16 months, and a serious attempt has been made at careful follow-up and epidemiological studies. Out of this experience certain impressions have been gained.

First, bacillary dysentery is widespread along our coastal and Gulf regions as well as the Great Lakes. We called attention to the rôle played by ocean liners coming into New York, having discovered outbreaks which occurred on 3 of them and possibly a 4th.¹

Second, the disease is frequently unrecognized even during intramural hospital outbreaks. This is particularly true with regard to Sonne-Duval dysentery in children who exhibit very little discomfort and only a slight pyrexia in spite of frequent bloody stools.

Third, inadequate bacteriological and serological studies sometimes account for the failure of diagnosis in hospitals. We have pointed out that repeated cultural, phage and serological studies must be made; that the positive culture bears an inverse relationship to phage and agglutination titer, the first commonly being negative after about the 10th day when phage and agglutination titer become positive. We have suggested careful technical attention to details in agglutination studies, using a variety of agglutinable strains (we

use Shiga, Flexner Y, atypical Flexner-Jersey City, Mt. Desert, Sonne-Duval and Park-Hiss).

Fourth, the senior author believes that he has traced a common pathogenesis for bacillary dysentery and chronic nonspecific ulcerative colitis, the latter being a most insidious disease and apparently on the increase in this country. Twenty-two cases have given laboratory evidence of a previous bacillary dysentery and a review of all the cases seen since 1925 indicates their source as being New York City, Jersey City, New Orleans, Rochester, and Chicago, all of which are endemic areas for bacillary dysentery.

Fifth, bacillary dysentery appears to be definitely increasing in incidence in the United States and should no longer be regarded as a disease indigenous to the tropics. With these facts in mind, we were prompted to study 300 control sera in the New York City area taken from individuals with no clinical evidence of bacillary dysentery.

Technical procedure—Table I illustrates a typical set-up in which 3 dilutions of each serum were tested against the following strains of *B.*

dysenteriae, viz.: Flexner Y, atypical Jersey City, Mt. Desert, Sonne-Duval, and Shiga. The serum was so diluted that upon the addition of an equal quantity (0.5 c.c.) of broth culture, the resulting dilutions were 1:20, 1:40 and 1:100. The organisms were added in the form of an 18 hour, sugar-free broth culture (pH 7.0). In the actual tests it was found advantageous to test 10 sera at one time. This allowed for greater simplicity of technic and increased uniformity in the reading of the results. Incubation was carried out for 4 hours at 55° C., but final readings were taken only after the tubes had remained in the ice box over night. The readings at the time were always more distinct than those obtained immediately after incubation. A positive result was recorded in every case where definite agglutination was visible even though it was not complete. A reading of ++ or greater was considered positive. Previous to their use in the actual tests all cultures were tested for purity, for their action on carbohydrates, and for their agglutinability with known immune sera. It was also determined that the organisms were all of the S

type. Saline, 0.85 per cent, was used as a diluent.

The results of this study are shown in Table II. It will be noted that diagnostic titers of 1:100 were obtained in 4.3 per cent against the Flexner Y and Shiga strains, in 5.7 per cent against the Jersey City strain, in 8.3 per cent against the Mt. Desert strain which is common in New York City, but in only 1 case (0.3 per cent) against *B. dysenteriae* Sonne-Duval. Inquiry revealed that the patient was suffering from an acute attack of bacillary dysentery, this case being included in our series because the diagnosis had been completely overlooked.

Two possibilities are suggested by these figures, viz.: first, the relatively high incidence of diagnostic agglutination titers and, therefore, presumptive evidence of a previous dysentery infection (4.58 per cent average for all strains); second, the notable absence of high titers against *B. dysenteriae* Sonne-Duval. The first observation is confirmatory, to a limited degree, of Ritchie's work⁵ in which 792 sera gave a titer of 1:32 against the Shiga strain in 30 per cent and a titer of 1:64 against the Flexner strain in 41 per cent. The absence of high agglutination titers against the Sonne-Duval strain may be due to the comparatively recent

introduction of this form of dysentery into New York City or to the fact, as we have noted repeatedly in our cases to date, that in most instances agglutinins produced by this organism rapidly disappear after a few weeks. We have not seen a persisting titer of 1:100 in the follow-up studies of a single recovered case in our series. Sonne^{6,7} called attention to the low titers obtained in most of his cases. Smith and Fraser,⁸ moreover, regard a titer of 1:50 as diagnostic of a previous Sonne-Duval infection, a level distinctly lower than that commonly accepted for the other dysentery strains. These investigators, working in Aberdeen, where the Sonne-Duval type of dysentery is of relatively frequent occurrence, obtained a titer of 1:50 in 24 per cent of 138 normal persons. They therefore concluded that the disease was widespread in the region studied. These figures are significant therefore when compared with our control studies in the New York area. We have furnished figures, moreover, to indicate the increasing incidence of Sonne-Duval dysentery in New York City where most of the recognized cases occur in hospital outbreaks.

Working along similar lines with the dysentery skin reaction, Brokman and Popowski⁹ found positive skin reactions against Shiga-Kruse toxin in 51

per cent of children up to the age of 3 years, in 27 per cent between the ages of 4 and 15 years, and in 59 per cent of adults between the ages of 16 and 23. They used 1/100 rabbit m.l.d. Using 0.1 c.c. of a 3 per cent dilution of the toxin intradermally Brokman and Przesmycki obtained positive reactions in 80 per cent of 1,000 individuals examined.¹⁰ Neutralization tests and control studies indicated that these reactions were caused not by the injection of a foreign proteid, but by the absence of humoral antitoxins from the blood. Our series is as yet too small to permit any accurate deductions, but it appears that the positive skin reactions like agglutination titers vary considerably depending upon the prevalence of bacillary dysentery in the region studied.

In connection with agglutination studies in Sonne-Duval dysentery we wish to call attention to two possible sources of error. We consider this important because we must not add inaccuracy of technical procedure to

the difficulties of clinical diagnosis (for it is remarkable how comfortable some children with the bloody diarrhea of Sonne-Duval dysentery really are). Braun and Weil¹¹ have pointed out the lack of cross-agglutination between R and S forms. More recently Koser¹² and coworkers and Johnston and Kaake¹³ have stressed this characteristic in explaining apparent paradoxical findings. Wiseman¹⁴ and Fyfe¹⁵ called attention to the inagglutinability of some freshly isolated Sonne-Duval strains.

It may be of interest to note the incidence of multiple agglutination titers of 1:100 in our control series. These were Mt. Desert and Shiga 1.3 per cent; Jersey City Flexner strain, Mt. Desert and Shiga 0.3 per cent; Flexner Y, Jersey City and Mt. Desert 0.3 per cent; Flexner Y, Jersey City, Mt. Desert and Shiga 0.3 per cent; Flexner Y, Jersey City and Shiga 0.3 per cent.

19	M.W.	$\frac{3}{4}$	Mt. Desert 1:320
20	S.K.	$\frac{3}{4}$	Flexner Y 1:160

is not definitely known. Our cured acute cases of Flexner Y and Mt. Desert dysentery followed up to date showed for the most part a persistent high titer at the end of one year. Our Sonne-Duval cases are an exception, as stated above. The follow-up on the cases of nonspecific ulcerative colitis studied by one of us¹⁶ is very interesting. The familial incidence is high, the first 3 patients in Table III being a brother and two sisters. The evidence at hand points very strongly to the origin of this disease as a primary bacillary dysentery infection. The de-

tails of these cases have been reported.

The data herein presented indicate the prevalence of bacillary dysentery in one area on our eastern seaboard. Supplementary serological findings suggest the close etiological relationship between bacillary dysentery and non-specific ulcerative colitis.

A Modified Technic for the Detection of the *Escherichia-Aerobacter* Group in Milk

ANDREW MOLDAVAN

Bacteriologist, Guaranteed Pure Milk Co., Ltd., Montreal, Quebec

IN the 1934 edition of the A.P.H.A. *Standard Methods of Milk Analysis*, a provisional method for the detection of *Escherichia Aerobacter* organisms in milk is described with a forewarning that "discretion must be observed in the application of this determination to the specific purpose intended and particularly in the interpretation of the results obtained."¹

Lochhead and Johns have also pointed out that "in milk analysis the coli count has not the same public health significance it has in water analysis."²

It is generally agreed that in most cases, positive results from samples of pasteurized milk are due to non-fecal, "dairy-bred" organisms, the presence of which indicates faulty sterilization or improper pasteurization rather than fecal contamination of human origin.

For nearly two decades the *Escherichia aerobacter* fermentation test (2 per cent bile brilliant green lactose peptone) has been carried as a complementary test to the standard plate count by the Quebec Provincial Laboratories, the Montreal Health Department, and by industrial laboratories. That it is possible under practical conditions to produce pasteurized milk consistently free from gas-forming *Escherichia aerobacter* organisms has been conclusively demonstrated by these authorities.³

The inverted tube (Durham) or the

Smith fermentation tube technics may be used although Section H-VI of the A.P.H.A. provisional milk standards recommends the use of inverted vials. Unfortunately, the description of the technic of inoculation and distribution of the inoculum in the medium is not so elaborate as that of the standard plate method, and allows for considerable variation from one laboratory to another. While the ratio of inoculum to medium is well defined, the size and diameter of the tubes and the mixing technic are not described.

AGAR SEALED FERMENTATION TUBES

I—Negative—48 hours.

II—Positive — 8 hours (Bubbles).

III—Positive —16 hours.

IV—Positive —36 to 48 hours.

One way of determining the ratio of milk inoculum introduced into the inverted gas tube is to test its content for butter fat. The butter fat tests (in skim-milk Babcock bottles) show that the amount of milk introduced into the inverted gas tubes varies from 0.1 to 0.5 c.c. for 1 c.c. inocula, depending upon the diameter of the tubes and the degree of agitation-rotation. In the close-arm of Smith fermentation tubes the ratio is about 0.5 c.c. Positive results should not therefore be referred to as positive for 1 c.c. but as positive for less than 0.5 c.c. of milk.

To secure a greater accuracy several British and American workers are using ordinary test tubes, sealing the inoculated medium with sterile paraffin. The chief disadvantage of paraffin is that it renders cleaning of tubes very cumbersome, especially where a large number of tests is made.

Since 1931 this laboratory has used agar in preference to paraffin. The technic was demonstrated at the time to members of the A.P.H.A. Laboratory Section attending the Montreal meeting.

The tubes are filled with 9 c.c. of 2 per cent bile brilliant green lactose peptone medium (Difco) and sterilized. The plug material consists of sterile 2 per cent agar (Difco). As soon as the medium has been inoculated with 1 c.c. of milk, the tube is rolled between hands to insure a uniform distribution, 2 c.c. of the melted 2 per cent agar (45° to 55° C. according to room temperature) is poured slowly along the tube's side where it cools rapidly (37° C.), and forms a solid cylindrical plug over the medium. A certain

amount of dye diffuses through the agar plug and inhibits extraneous growths. Rising milk fat in the tube acts as "piston-grease" making the agar plug practically air-tight.⁴

The advantages of this technic are the following:

Results can be reported definitely as positive or negative for 1 c.c. of milk independently of the tube's diameter or the degree of agitation.

The A.P.H.A. provisional method calls for a 48 hours' incubation period so that under practical conditions 3 days have elapsed before any action can be taken to correct the source of contamination, long after the milk is consumed.

In agar-plugged tubes, traces of gas (bubbles or foamy layer) will appear earlier or at any rate are more noticeable than in submerged inverted tubes. In positive samples, gas will be detected within 16 hours and in cases of gross contamination within 8 hours, so that early action can be taken as regards equipment sterilization. In exceptionally serious cases, the contaminated milk supply may be condemned before it is actually distributed.

Another minor advantage is the greater ease with which tubes can be thoroughly cleaned as compared with the cleaning of greasy and stained small inverted tubes or Smith tubes.

Simultaneous Immunization Against Smallpox and Diphtheria*

CHARLES S. STERN, M.D.

Commissioner of Health, West Allis, Wis.

THE practical advantages of immunizing a child against two diseases at one sitting are obvious. In private practice as well as in the mass immunizations by public health agencies, it is often difficult to have children return for successive injections. Diphtheria immunization by the one dose alum toxoid method has done much to simplify this difficulty. The simultaneous use of the one dose method of diphtheria immunization with vaccination against smallpox is herewith presented.

Multiple immunizations of this character have been found as effective as separate immunizations, and unaccompanied by any greater reactions than are produced by single injections of the respective materials.

The power of the animal body to produce specific precipitins following the injection of several antigens has been established by Hektoen and Boor; Isabolinski, Judenitch, and Karpatschewskaja; and others. In human subjects, scarlet fever vaccine and diphtheria anatoxin has been given simultaneously by Isabolinski and his coworkers; diphtheria and scarlatinal toxoid by Tsen; diphtheria anatoxin and antityphoid vaccine by Dopter; diphtheria toxin-antitoxin, typhoid vaccine, and smallpox virus by McKean;

diphtheria toxoid and smallpox virus by Reckling.

Since June, 1934, we have used the simultaneous multiple method of immunization against smallpox and diphtheria in all children presented for immunization against these diseases. These children had not been previously immunized against smallpox or diphtheria.

We have tabulated the results of 100 consecutive cases of school and pre-school children who were simultaneously inoculated with smallpox vaccine and alum precipitated toxoid, in Table I.

The deltoid area of each arm was thoroughly cleaned. The left arm was dried, a drop of vaccine was placed on the deltoid region. The "multiple pressure" method for vaccination was used. The skin on the right deltoid was painted with tincture of merthiolate solution, and 1 c.c. of alum precipitated toxoid was injected subcutaneously.

During the first 72 hours following the inoculations the staff nurses visited the home to ascertain whether or not there was any immediate local or constitutional reaction. There were no immediate ill effects in any of the children. There was a slight rise in temperature in two of the children noted the evening of the day of the inoculation. One child had a mild local reaction at the site of the alum precipitated toxoid inoculation. In one

* Preliminary Report.

b. Pain at site of alum precipitated toxoid inoculation.

c. Vomiting on second day following inoculation.

* Material Used: Alum precipitated toxoid 15 antigenic units per c.c.; glycerinated smallpox virus vaccine.

instance the child had a vomiting spell on the second day following the administration of the simultaneous inoculations. The reactions were mild and without ill effects.

The simultaneous multiple immunization against smallpox and diphtheria did not affect the immunity or rapidity of immunity produced against diphtheria as indicated by the Schick test readings. Of those preschool and school children whose immunological status to diphtheria was unknown, 95 per cent became Schick negative after receiving the alum precipitated toxoid in our routine simultaneous multiple immunization. These results compare favorably with children who received but a single inoculation of alum precipitated toxoid. It is interesting to note that 98 per cent of the children in this group had a positive vaccination reaction.

We have compared our results of simultaneous multiple immunization with the results we have obtained from the single immunization method formerly used in diphtheria and smallpox prevention. From our files, 100 cases

of preschool and school children whose immunological status to diphtheria was unknown, and who had received alum precipitated toxoid were analyzed. The reactions and the result of the Schick readings were tabulated—94 per cent of these children became Schick negative. The reactions noted were mild.

The result of vaccination against smallpox was noted in children who had previously been inoculated against diphtheria. The percentage of positive smallpox "takes" was somewhat less than in those children who received simultaneous immunization against diphtheria and smallpox.

CONCLUSION

1. The simultaneous multiple immunization against smallpox and diphtheria is a practical method applicable as a routine procedure in mass immunization as well as in private practice.

2. The simultaneous immunization against diphtheria and smallpox is a safe procedure.

3. The simultaneous immunization against diphtheria and smallpox is effective.

GASTRIC LAVAGE FOR THE DETECTION OF TUBERCLE BACILLI IN CHILDREN

DURING the past two years a number of articles have appeared on the finding of tubercle bacilli in the gastric contents of children. Children do not raise sputum and expel it as adults do, but swallow what gets into the mouth from the air passages. It is generally assumed that tubercle bacilli found in the stomach contents have their origin in the lung. It is evident that other sources may exist, such as raw milk or a tuberculous lesion somewhere in the upper air passages or tonsils. It is possible also, though improbable, that a tuberculous lesion of the stomach may exist.

Gourley¹ examined 59 children with pulmonary tuberculosis over a period of 2½ years by gastric lavage and guinea pig inoculation, her object being to determine whether or not it was possible for children with parenchymal lesions to be free from tubercle bacilli, and also to determine when an open case becomes a closed one. Autopsies were performed on the guinea pigs from 4 to 8 weeks after inoculation and no case was considered positive unless tubercle bacilli were demonstrated. Thirty-one children gave negative results, and of these, 29 per cent were under 6 years, while of the positive group, 50 per cent were under this age. The intracutaneous tuberculin test was positive in all the negative cases. Of the 28 children who gave positive results by gastric lavage all had run favorable clinical courses. The author believes that the results, which are given in detail in the original article, indicate all types of parenchymal lesions in childhood tuberculosis are open cases, but positive conclusions are held in abeyance pending further work.

Mishulow, Kereszturi, and Hauptman² examined the feces and stomach contents of 60 cases with the object of studying the comparative value of methods of diagnosis. In 12 cases the feces, and in 16 the gastric contents, were positive on smear examination, 11 of the group being positive for both

feces and gastric contents. Of 44 whose gastric contents were negative on smear examination, 4 gave positive results by inoculation of guinea pigs, bringing the total number of positives by the gastric lavage method to 20, or $33\frac{1}{3}$ per cent. The examination of feces is more practicable than gastric lavage, since it may be repeated frequently with ease.

Nalbant³ has reported on 72 cultures and guinea pig inoculations from the feces and sputa of 65 children under 15 years of age, 24 of which showed tubercle bacilli. Nineteen showed no demonstrable parenchymal lesion by either physical or radiological examination and were considered negative as far as the lungs were concerned. Among these, tubercle bacilli were found in the sputum or feces of 7. The other 17 positives were from children with a childhood type of tuberculosis.

This author summarizes the literature on the examination of gastric contents of children and notes that of a total of 197 children without pulmonary tuberculosis, but including bone and joint cases and tuberculous meningitis, 81, or 41 per cent, showed tubercle bacilli in either the gastric contents or the feces, indicating active disease.

Hacker and Wallis⁴ examined the gastric fluid of 50 children by animal inoculation, waiting an average of 40 days to make the examination of the inoculated animals. They found that 15 of the 50 children had open tuberculosis, and that younger children were positive for bacilli more often than the older ones. This they believe to be due to the fact that in younger children primary lesions are more frequent, which results in a greater tendency to form open tuberculosis.

While these studies were apparently undertaken for other reasons, such as have been mentioned, they suggest the interesting possibility that such cases may be responsible for obscure cases of infection often found in children. Nalbant believes that the organisms may come from a receding childhood type of parenchymal infiltration which cannot be detected by the X-ray but which is not yet completely free of bacilli. Another supposition is that the bacilli may come from the breaking down of a lymph node and the pouring of its contents into the bronchus from which it goes to the mouth and is then swallowed. He considers that children with tubercle bacilli in the stools and stomach are a menace to uninfected children and should be isolated in a sanatorium and treated as tuberculous. Such children should be repeatedly examined and not allowed to mix with others until bacilli free.

These interesting studies may serve to clear up some of the difficulties in tracing the origin of obscure cases, and it is evident that this method of examination should be carried out to determine when children become clinically well of their tuberculosis and free from tubercle bacilli. The wide adoption of such methods should be at least one step in the prevention of the disease.

HUMAN INFECTION BY THE AVIAN
TUBERCLE BACILLUS

THE question of human infection by the avian tubercle bacillus has come up many times and a considerable amount of material has been written concerning it. A few reports of such infection seem to be authentic. The majority of them appear to be open to question. The many ways in which man is exposed to the avian tubercle bacillus and the very few cases, even doubtful ones, which have been reported, indicate that if the avian bacillus can infect man the actual occurrence is rare.

The avian type of the bacillus has been found in eggs by a number of responsible workers. Klimmer, 1931, held that as high as 3 per cent of market eggs and 10 per cent of eggs from tuberculous fowls contained avian bacillus, but an investigation by Lichtenstein in 1932 showed that only 0.38 per cent of eggs in stores and dairies in Leipzig gave positive results. Against these reports are many in which eggs were found to be free from this infection.

Cattle are occasionally found to be infected by the avian bacillus, and during the last few years Van Es has published a number of articles showing that this type of organism is responsible for a rather high degree of infection. In specimens from 115 cattle having only isolated lesions, such as solitary lymph nodes, the avian organism was found in a little more than 12 per cent. In 258 swine with discrete lesions, the avian organism was found in 199, or 78.6 per cent. The percentage of so-called natural infection of animals varies in different countries. In England approximately 30 per cent of the localized tuberculosis in swine is due to the avian organism. Avian tuberculosis has been found in a number of animals, such as the horse, sheep, and rabbit, but is rare. It is especially liable to be found in both cattle and hogs in those cases which show discrete lesions.

The avian organism is found occasionally in milk. In one report covering 400 samples, the avian bacillus was found 9 times by culture. In this country meats are almost invariably cooked before being eaten. Eggs offer a slight possibility of infection, and also milk, but at worst the opportunities do not seem to be excessive.

Branch,¹ in 1931, made a study of the literature for what he considers authenticated cases. He has found 14, 5 of which were renal tuberculosis, 1 of pulmonary involvement; 1 splenic involvement; 1 lesions of mesenteric lymph nodes; 1 cutaneous abscesses; ulcers of nose, mouth and intestine; 1 ulcers of palate and of skin of nose; 1 septic fever; ulcers of tongue, lips and scrotum, swelling of knee joint; 1 ulcer of leg; 1 abscess of leg; and 1 septic fever, Pel-Ebstein's syndrome. Three of the cases occurred in poultry workers or farm hands, 4 giving a positive avian tuberculin test. In 9, the type of organism was confirmed by animal inoculation, including fowls. In only one case is an autopsy recorded. Branch gives many references, but apparently he does not consider any other cases authentic or as having been proved.

In 1926,² there were reported by Mayo and Hendricks 2 cases which they claimed were "demonstrated surgically and pathologically" to be avian tuberculosis. The report of the pathologist was given, but no cultures were mentioned. If there is an outstanding characteristic of avian tuberculosis it is the enormous number of bacilli found in the lesions. In the absence of the cultivation of the bacillus from the lesions, these cases must be considered as lacking authenticity.

Indeed, from the variety of symptoms and lesions described in the few authentic cases one is inclined to conclude that there are no certain surgical and pathological findings.

Gloyne,³ who has reviewed the work of Branch, states that clinical diagnosis of infection by the avian bacillus is impossible. Branch gives a number of symptoms such as " (1) long continued intermittent fever, with enlargement of the spleen, metastases in skin and lymph nodes (a type which may be confused with Hodgkin's disease or, as Löwenstein suggests, with leukaemia); (a) cutaneous lesions of four different types—(a) an aphthous septicemic form with changes in bones and joints; (b) a sarcoid form; (c) a gumma-like lesion; and (d) a local ulcerous form, the ulcers tending to heal and recur (the differential diagnosis here lies between syphilis, atypical tuberculosis, sporotrichosis or even leprosy); (3) a urogenital form in which a rapid disappearance of the bacilli following treatment with avian tuberculin has been reported."

Bacteriologically, the great diagnostic points are cultures and the inoculation of suitable animals, such as fowls and rabbits. It is suggested that as guinea pigs are more used than any other laboratory animal for diagnostic purposes, some cases of avian tuberculosis may be missed, as this animal shows slight or no susceptibility.

The tests with avian tuberculin are in some instances found to be extremely sensitive—up to 1:100,000 dilution—while old tuberculin gives a feeble or no reaction in such cases. A serological classification has also been developed by employing agglutinin absorption tests with antigens of avian tubercle bacilli.

No evidence as to the portal of entry has been determined in any human case, but the digestive tract seems to be the most logical route except in some of the skin cases occurring in those working with poultry. In birds the route of infection is typically alimentary.

The evidence indicates that the avian tubercle bacillus occasionally is found to be infective for man, but practically, as far as the writer has been able to determine, the danger is very remote. Since apes and monkeys are highly resistant to the avian bacillus, it is not unreasonable to expect a similar resistance in man.

It seems a pity, in fact it is reprehensible, that cases have been reported without adequate bacteriological study. Such cases as seem authentic indicate that the avian bacillus in man produces a low grade infection, but there are few reports of autopsies, and from a rather extensive study of the literature, one is justified in doubting the correctness of a number of the reported cases and in speaking very cautiously about avian infection in human beings.

NOTE: The study by Branch was made with reference to the reported association of the avian organism with Hodgkin's disease.

The Open Forum

REGINALD M. ATWATER, M.D.

Executive Secretary, American Public Health Association

THE WIDE OPEN SPACES

THE Executive Secretary spent the month of July in the territory of the Western Branch of the Association. The annual meeting of the Branch was held in Helena, Mont., July 1-3 under the Presidency of Walter H. Brown, M.D. An excellent program was provided and the attendance was good. Altogether there was a splendid meeting which centered quite largely on some of the special problems of the West, like Rocky Mountain spotted fever, rodent plague, and tularemia. One of the outstanding features of the program was the report by the Committee on Health Education of the Branch. The section of this report dealing with radio will appear in the October issue of the *Journal*. It is a fine example of what can be done by such a committee of a Branch.

Following the meetings in Helena there was an inspection trip to the Rocky Mountain Laboratory of the Public Health Service at Hamilton, Mont., where R. R. Parker, Ph.D., explained the special work of the Laboratory and the preparation of the vaccine against Rocky Mountain Spotted Fever.

Any who may have had doubts as to the necessity or the desirability of a Western Branch would have found their doubts removed had they been at Helena. With such a meeting it becomes possible to make available much of inspiration and information to public health workers who otherwise would be unable to attend so stimulating a meeting in their professional field. The new president of the

Western Branch is W. F. Cogswell, M.D., State Health Officer of Montana. The President-elect is H. E. Young, M.D., Minister of Health of British Columbia. The next meeting of the Branch will be held in Vancouver, British Columbia, in 1936, in conjunction with the Canadian Public Health Association and several other related organizations.

AN IMPORTANT DOCUMENT

THERE is a continuing interest in the Reports of the Committee on Professional Education mentioned in the *July Journal*. These reports will be presented for consideration by the Governing Council at the Milwaukee meeting. The reports cover the subjects of professional qualifications for health officers and public health engineers. Prolonged consideration has been given to these topics for several years and the present committee under the Chairmanship of W. S. Leathers, M.D., has put much effort into these reports. There is considerable difference of opinion manifest to date and it is to be hoped that a proper group judgment can be reached in Milwaukee. By order of the Executive Board, copies of these reports as they will be submitted to the Governing Council are available on request from the Executive Secretary.

HEALTH COUNCILS IN ACTION

AMONG the Health Councils which I visited this summer, that in Tacoma, Wash., stands out, partly because it is very new, and partly because it has made striking progress since its

organization less than a year ago. A health survey was awarded Tacoma in 1934 in the City Health Conservation Contests and Carl E. Buck, Dr.P.H., made the study during the fall, recommending among other things the formation of a Health Council. An inclusive group of agencies was brought into the organization, and the account of the work so far shows that the official health department has been vastly improved by coöperative effort and the school health service has been raised to a new level. The Junior League has found the right person to serve as organizer of information on health topics for 450 local clubs and a surprising effect can be seen in making the city health conscious. A very interesting development has been the creation of classes in public speaking for local doctors and dentists with the aim of making these professional people more effective in educating the public. Along with this has gone a very comprehensive study of medical economics so that Tacoma need not depend on estimates made elsewhere in this important field.

Always on the alert for new possibilities, the Tacoma Health Council has established relationships with the Tacoma Fair Association so that there is available not only space for an exhibit of their health council activities, but there has been placed in the hands of the Council a complete censorship over all the Fair exhibits so that it will be possible to eliminate undesirable publicity and to exclude pernicious advertising on health subjects. I hope to see many cities take the initiative in this manner.

A SIGNIFICANT BIRTHDAY

THE year in which the Committee on Administrative Practice celebrates its 15th anniversary has been marked so far with many requests for health surveys and appraisals of specific activities. It would be indeed gratifying

if the Association were in a position to meet all the requests for aid. It is especially noteworthy that the last 15 years have witnessed a profound change in the attitude of many official health departments which formerly very strenuously resisted any such appraisal and now welcome such a study with great eagerness, knowing from experience that there often follows a very wholesome wave of public support and appreciation.

Based on the 1934 Health Conservation Contests, free surveys have been awarded to Spokane County, Wash., and to Louisville, Ky. These will be completed during the fall by the staff, and several other localities will also be surveyed.

The Second Rural Health Conservation Contest and the Seventh City Health Conservation Contest have been announced. Field work has begun and particulars may be obtained from Dr. Buck.

WHAT OF FEDERAL AID?

IT is of great significance that the federal government has embarked on a much expanded program of federal aid to states for health services. As I watch the preparations over the United States for these new funds I am impressed that it still remains to be seen whether these very large resources are going to lift the level of professional public health or whether these funds are to be used in devious ways of partisan politics where chicanery and guile will replace the widest service to the greatest number. I am sure in advance of some areas where these funds will be wisely used, where broad public interest will transcend all considerations of private profit. In these areas the essential difference goes back to the kind of people who will administer the funds in these states. I celebrate the advantages of high minded leadership in such critical times!

CAN WE MEET THE NEED?

THESE new federal funds also throw into relief the need for more persons with high professional qualifications and I am pleased to see how thoughtfully plans are being laid for training courses for medical, nursing and engineering personnel. Whatever conclusions may eventually be reached about the required length of graduate instruction courses in public health, there must be agreement that the new personnel in this field will be much better off if they can be exposed in classroom and field to those with high professional standards. Even if these courses now must of necessity be short, there is a fine opportunity for the university departments already giving these courses to extend their influence and by this means to advance greatly the cause of good public health work.

Surely the opportunity for service which faces the American Public Health Association was never greater. It is my earnest hope that this Association may live up to the possibilities of these new days and through its many activities may add new strength and support to the busy hands of those professionally engaged in promoting our public health.

EPIGRAM

"While public health is the foundation of the happiness and prosperity of the people, and its promotion is recognized as an important function of government, how wide is the gap between what is achieved and what might be realized; how inadequate is the understanding of the public concerning the means adopted to secure the best results."—*William H. Welch.*

PUBLIC HEALTH EDUCATION*

Much Wanted at Milwaukee—A request for various types of materials, as well as program features for Milwaukee, has been circulated quite widely.

If a copy failed to reach you will you please write promptly to the New York office of the A.P.H.A.?

Possibly as Never Before—This year those who are doing any form of health education, of presentation and of interpretation of public health, need the inspiration of the Annual Meeting.

Nothing can quite take the place of what may be gained through meetings, "lobby conferences," and health education headquarters.

Here's looking for you!

Please Make It Your Headquarters—Public Health Education Headquarters will have space and equipment at Milwaukee to make it attractive and helpful to all concerned.

Please make it *your* headquarters. Come early, and come often. Make yourself known to those you will meet. Have questions to ask. Bring a full quota of ideas of your own.

There will be demonstrations and other events. Get a time table. Electrical transcriptions, amateur and other 16mm. movies, strip films will be demonstrated. Several group consultations will be held. Other features are hoped for.

The editor of this department serves as chairman of the committee in

charge of headquarters. All readers of this department are invited to help by giving a certain amount of time at headquarters.

"Can It Now Be Told?"—Under this title Dr. D. B. Armstrong reviews a set of problems of almost daily concern to those who participate in health education.

In a 4 page reprint Dr. Armstrong considers when to tell the public, what to tell, and what cannot be told—because it isn't so, or we don't know. Here is Dr. Armstrong's proposed classification of "facts":

I. Assured Health Facts:

- A. Those universally and practically applicable
- B. Those theoretically sound but limited in application because of the imperfections in available methods, doubt as to timeliness, or for other reasons

II. Near Facts:

- A. Those about which there is a growing certainty, though as yet no absolute scientific assurance
- B. Those once generally accepted but about which there is an increasing element of doubt

III. Assured Health Fallacies.

Get a copy from Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y., and re-read it, say, every September?

Preventive Medicine via Talkies—Paul A. Smith, inspector, Southern Berkshire Union Health District, 54 Castle St., Great Barrington, Mass., writes:

In connection with this year's health education activities we have thought of the possibility of using the moving picture as a

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

medium of teaching the public significant facts on preventive medicine. We are confident that the local theatre would be entirely coöperative if we could secure a few short interesting films of 15-20 minutes' duration. The general public now has grown so accustomed to talkies that I feel any films we secure should be of that type.

If you know of any suitable films which might be used, and where they can be obtained, we would appreciate hearing from you.

Our reply to Mr. Smith:

There are almost no talkies on health subjects in so far as we know. Such pictures not only are expensive, but they are difficult to produce.

Please write to the Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y., about what they have.

We hope that publication of your request in *American Journal of Public Health* may bring you additional information.

A Package Library for Physicians—The package library for exhibition in local medical conferences or where physicians congregate "has been completely revised." The library is available for loan through state tuberculosis associations.

The Parent-Teacher Audience—To understand the parent-teacher audience, and to learn what that audience through its local leaders is learning about health, you will wish to see the publications of the National Congress of Parents and Teachers, including its periodical, *The National Parent-Teacher*, 1201 16th St., N.W., Washington, D. C. 15 cents a copy.

Some recent articles:

May, 1935: Adapting food to different ages. Training children for safety. Sunburn or sun tan, by S. J. Crumbine.

June, 1935: Summer-time: a healthy time for babies. Handling the milk question. Rest and sleep in summer, by S. J. Crumbine.

July, 1935: Getting the most out of nature's boom days, by H. N. Bundesen. The road to dental health, by J. A. Tobey.

An effective feature is "It's Up To

Us," a part page lesson for parents which might well be adapted to health teaching. Two pictures contrast the wise and the unwise, each with two or three line dialogue caption, plus a lower paragraph of application.

"I Give and Bequeath"—The convincing editorial which appeared under this heading in the June issue has been reprinted and mailed to members.

This department would emphasize that gifts to the A.P.H.A. render a nation-wide service. And this service reaches into the communities which have well developed public health services, much to their advantage, and at the same time is helping to bring nearer that day when every individual in every section of the country, and of all the North American countries, will benefit by public health services.

Will those who are doing health education make at least one mention of this possibility? Here and there in most communities are those who respond to the vision of a national service. And usually those who can see the larger field will not be any less interested in the local work.

Physicians Protest Radio Censorship — "Physicians Protest Commercial Radio Censorship" heads the statement presented by Dr. W. W. Bauer at a hearing before the Federal Communications Commission, May 15, 1935. In stating the handicaps now existing Dr. Bauer said:

The American Medical Association, while duly appreciating the coöperation of the broadcasting interests, nevertheless is constrained to represent to the Commission that certain practices and situations in the field of educational broadcasting require attention and should be modified if possible in the interest of the listening public.

Speakers on scientific topics are limited in what they may say, with particular reference to the following matters:

(1) Medical speakers on health topics are

not permitted to make general statements of established fact which may interfere with products advertised by radio, even when no specific product is mentioned and when the truth of the proposed statement is not in question. This is entirely aside from specific objections to certain medical advertising.

(2) Speakers are limited with respect to certain topics, particularly the important public health problem of venereal diseases, by virtue of a public taboo on mention of these topics. It is recognized that this taboo is not a creation of the radio industry, but is merely reflected by that industry. Nevertheless, it puts a great handicap in the way of public health progress. The so-called social or venereal diseases, and particularly syphilis, constitute, in the opinion of many competent observers, the most important public health problem before the United States today.

(3) Radio speakers are required to accept censorship from the owners of broadcasting facilities or incur the penalty of being barred from the air.

Dr. Bauer submitted four points which he hoped would be adopted by the Commission. In *Education By Radio*, National Committee on Education by Radio, 1201 16th St., N.W., Washington, D. C. July 11, 1935. *Free*. This little publication and this organization lead in the campaign for protection of the educational use of broadcasting. Ask to be put on their mailing list if you wish to keep in touch with developments.

No Restrictions in Ohio—Dr. A. L. Van Horn, chief of Bureau of Child Hygiene, Ohio Department of Health, Columbus, reports as follows:

For the past 3 years the State Department of Health has sponsored a weekly broadcast over station WOSU, which is owned by Ohio State University. During this time no restrictions whatever have been placed on subject matter and although no complete broadcast has been devoted to the subject of venereal diseases, still we have made frequent references to syphilis.

Recently we have expanded our health education program by radio to include three other Columbus stations (WBNS, WAIU and WCOL) so that we are now on the air 4 days a week.

Many Names for a Single Process—A process of reproduction for health education material, not widely used by health agencies, offers valuable possibilities. It is especially good when a pamphlet or other publication is to be reprinted. It offers the possibility of using a variety of ready made photographs, or sketches without making engravings. Typewriting can be substituted for printing type text.

We would like to hear from readers as to their use of this process.

Inland Printer, 205 W. Wacker Drive, Chicago, Ill. (May 1, 1935: 40 cents) considers the subject from the standpoint of the printing trade, but several paragraphs will be helpful to laymen:

. . . the confusion of names under which the business operates—planographing, offset printing, photolithography, offset lithography, not to mention the various special names coined by individual concerns, such as "planoprint," "photolith," and so'on. . . .

The word "planographing" refers to printing done from a plane surface, as distinguished from relief printing, where the letters and pictures stand out from their bases, and intaglio printing, wherein the letters and pictures are cut into the printing surface. The distinction is akin to that of birds, animals, and worms, one of which is above the earth, one on the earth's surface, and one underneath.

We might say that lithography in general is one form of planograph printing. As actually used, however, planographing has a far more restricted meaning. It refers to printing by offset, wherein simplified lithographic technic is used to do simplified types of work, most of them in black and white, many of which were previously done by letterpress. . . .

One of the biggest sales problems that offset printers have is to sell buyers of printing on using big pictures, action photographs, striking charts and graphs, and generous pen-and-ink illustrations. The general objective is to get printing buyers to tell more of their stories pictorially and graphically, and so reduce the number of words that need to be written and set in type.

The article warns the printer against "overselling" the cheapness and other

elements which need to be considered. Consultation with a reliable printer will meet these difficulties. Any process has its limitations.

Where to Get This Information?

—Here is one of the many letters asking for information difficult to supply:

I shall greatly appreciate it to have a list of recent health films suitable to public health educational purposes. I should like to know the title, the size, and length of film, the producing agencies, and the cost of securing the rental of it.

I shall also appreciate to have your recommendation concerning popular health educational literature available from private agencies. What is available from the various sources, and what among this material is worth while.

No satisfactory answers are known to the writer, and no satisfactory sources of information.

Who should undertake the job?

Who will undertake the job?

Health Education in July, 1935, Journal—In *American Journal of Public Health*, July, 1935, are valuable references touching on health education.

In "Significant Aspects of a Recent Official Survey Concerning the Household Use of Milk in Philadelphia," by Egbert, pages 789-795, is a quotation from the study:

A relationship between publicity and increased milk consumption seems clear, but it cannot be concluded that it is a "cause and effect" relationship. The causal relationship may run from high consumption to knowledge of publicity, rather than from publicity to increased consumption.

Emphasizing the need for increased efforts to extend the use of milk the author says:

Too much credit cannot be given to every organization and agency that has had a part in the splendid educational work already done, and in aiding them and others to continue and increase the efforts they have made.

In "Function of the Laboratory

in the Epidemiological Control of Syphilis," by Arthur, pages 845-847:

We believe that the public is developing a better understanding of the disease and that the great value of early diagnosis and prompt treatment is more generally recognized. Recent publicity even in the newspapers and by radio, with many favorable comments, shows a growing interest. Health officials should be cognizant of this slow but apparent change in attitudes and make every effort to profit from it by progressing beyond the present more or less inactive statistical period to a more active epidemiological endeavor in the control of syphilis.

In "Industrial Health: An Expensive Neglect," pages 858-859, there is emphasized a field for health education of the worker, the public, and the legislator.

In "The Bulletin of Hygiene," page 860, attention is called to invaluable source material.

"The Contests" in "The Open Forum," page 862, refers to the publicity value of the Health Conservation Contests.

There is a review of "Recording of Local Health Work," by Walker and Randolph, page 876, a book of great interest to those who use record data in any form of publicity.

We hope that readers of this department note each month under "Applicants for Membership" those listed for Public Health Education Section. Some of us might feel inclined to send notes of welcome, and an invitation to participate in Section sessions at the next convention.

Hygeia for August, 1935—We wonder if the following articles in *Hygeia* might not suggest topics for radio talks:

Typhoid. Abscessed ears and mastoiditis. When children and animals mix (diseases of pets). Some popular fallacies about anemia. The curious thing called allergy. Balm at the door (tale of a medicine peddler and a country doctor). Nervousness: its causes and prevention. Foods in hot weather. Why the baby has eczema. Trained dogs guide

the blind. Heart disease after middle age. Theobald Smith (a pioneer scientist). Why should your child dance? Primitive medicine (among the Zulus). Decisions as to iodized salt. Injuries and first aid to the eye. Diet and the teeth. "Jake paralysis." On the feet of little children (right shoes and stockings). New Books on health. Questions and answers.

Under "School and Health":

Thinking straight about health. Some fun with superstitions. Solving health educational problems. New health books for teachers and pupils.

A Round Table on Health Education—At a recent meeting of the Advisory Council of the Milbank Memorial Fund one session was devoted to health education. From the report by Dr. Kendall Emerson we quote several paragraphs:

With our democratic tradition we can assume that the aim of education includes at least enlightenment, the promotion of careful thinking, and the creation of a critical attitude toward the problems each generation has to face.

Thus health education aims to enlighten the individual and the community on problems of public health and preventive medicine so that to an increasing degree reason can determine actions and decisions in this field.

Efforts to modify human attitudes and conduct with respect to health fall into two categories. One consists in *teaching* the latest developments in public health; the other in *promoting* certain health measures which the individual has to accept on faith. This raises the question whether health departments in their educational programs *urge* too much and *teach* too little, and if so, whether it is feasible for a health department to do more in the line of real teaching via the medium of adult education groups.

A comprehensive health department educational program should cover at least two phases: (1) popular health education, and (2) health education for professional groups. Schools health education is omitted, for usually this is considered the function of the school authorities.

The objectives of a well rounded program of popular health education are: giving the community a general knowledge and understanding of the work of the official health

agency; educating the public concerning health conservation, disease communication, and methods of safeguard; securing desirable changes in public opinion; creating a desire for new facilities; and educating the community to utilize the services of private physicians or, when financially unable, of clinics or hospitals. . . .

Some subjects should receive continuous emphasis throughout the year. For others intensive drives are the most effective.

Material used must have scientific accuracy, emotional appeal, concreteness, and simplicity.

The report notes some questions raised in the discussion, with a brief statement of the conclusions on each question.

Is health promotion the primary purpose of a health department educational program?

Should a health department do more in the nature of real teaching through organized adult education classes?

Considering that the major causes of present-day mortality center around heart disease, cancer, pneumonias, and accidents, can any health department divest itself of the responsibility of carrying on educational work in these fields?

What should be the policy of a health department in using commercial literature?

Are the present radio programs arranged by health departments effective?

Would it be practicable to prepare miniature exhibits of health department activities?

The discussion seems to have been largely in terms of the big city.

In "Policies and Procedures in Public Health," Milbank Memorial Fund, New York, N. Y.

School Health Bibliographies—The following bibliographies were revised in June, 1935:

"Health Education in Elementary Schools." For classroom teachers.

"Health Education: For Administrators and Instructors of Health Education in Junior and Senior High Schools."

"Health Education in the Rural School."

"Problems of Administration in School Health Education."

The following were revised at dates indicated:

"Some References on the School Lunch." April, 1935.

"Some References on Child Care and Training for Those Conducting Child Care Classes in Secondary Schools or Parent-Teacher Groups." Jan., 1935.

"Some Recent Contributions to Health Education." For those giving courses in health education. Oct., 1934.

"Some References on Dental Health Education." Oct., 1934.

"Supplementary Reading Materials for Health Education." Grades 1 to 9. June, 1934.

"Health Plays for School Use." Feb., 1933.

Apply for any of the above to American Child Health Association, 50 W. 50th St., New York, N. Y., *before October 1, 1935.*

These lists might well be studied by anyone preparing reading references for students, health workers, teachers, or others. The information given and the form in which it is presented are almost ideal. Surely such lists mean more and better reading by students and workers.

"A Prime Function of a Health Department"—"My editor and I agree that one of the prime functions of a health department (and when I say health department, the term includes the tuberculosis organization) is to keep the public informed regarding the activities of the organization," said City Health Officer R. L. Carlton of Winston-Salem, N. C.

Dr. Carlton, speaking before the Southern Conference of Tuberculosis Secretaries, said that this informing of the public

... can best be done through the medium of the newspaper by describing in readable, simple English those services which affect the common citizen in his daily life. There is no universal prescription as to how to present this picture. The people of one city may demand the sensational and unusual. However, the health worker is never justified in sacrificing accepted and proven facts for the sensational and startling portrayals of unproven and doubtful origin. He is most

successful who can mix the dry language and statistics of the scientist with the highly colored portrayals of the modern commercial advertiser. We can't all do this, of course—but that is an ideal toward which we should strive. . . .

There is no lack of material for news articles. In addition to stories of the department's activities there are never ending stories of communicable disease. When it is considered that 1 out of every 25 persons in the community had some form of preventable disease last year, that every one has a friend, an acquaintance, a member of his family, or a relative who contracted a communicable disease—a preventable disease—and was absent from school, work, or activities on account of it—we must concede that public health publicity is news. Stories regarding communicable diseases are current news if made timely. We did not submit articles on summer care of babies in December; nor write vacation hints in January; we did not discuss green apple tummy ache or like food indiscretions at a time when there were no green apples, but we made our stories timely, of interest to our people because concerned with things and conditions at hand now, today, not 6 months from now.

All life is the source of public health news for the health worker who wishes to utilize it. He can begin before the child is born with stories of prenatal instruction, and follow with articles dealing with the care of babies and tell of their troubles of the horrid "second summer," of the wrong ideas so many mothers have concerning the teething bugaboo, stories of how to feed and clothe and exercise the baby and how to prevent rickets and how to give him a sunbath and what not—and a dandy piece of publicity is the story of the well baby health station and of what mothers learn to do for their babies' welfare there. Publicity can stress the protection of babies and children against smallpox and diphtheria and typhoid; it can emphasize the prevention of many other diseases; it follows with stories of the preschool child and tells what happens on account of neglecting him; then getting him ready for school is the subject of more than one news story; followed with a host of stories as to what should be done in a health way for the child in school. Periodic health examinations are entitled to some publicity. The correction of defects in children and adults can always be used as the subject of an interesting story. Early diagnosis and treatment are to be stressed. The fight against tuberculosis has only been half won and this story is applicable everywhere—not forgetting the story

of the tremendous inroads this disease makes on our young adult population. The eradication of tuberculosis from cattle and its relation to the reduction of the disease in humans is an item of interest. The family medicine chest with its simple remedies and dangerous poisons in careless array; spring and fall house cleaning, sprinkling of streets, sewage disposal, quarantine laws, school inspection, the value of public health nursing, nutrition with a dozen stories regarding the foods we should eat and how to choose them, and so on through a host of other aspects of community health and personal hygiene.

Through such publicity the health department is able to warn the community of outbreaks of communicable disease and it is able to broadcast information so the public may know when to call a doctor and what to do in a given emergency.

Watchman! What of the Night?
—Several months ago a number of topics were briefly formulated in the hope that some of them could be discussed by the Section Council of the Public Health Education Section, or by the Section at the Annual Meeting.

These topics are submitted merely in the hope that local health councils, or other state and local groups of public health workers will give consideration to some of them.

Naturally we would welcome written comments for publication in this department of the *Journal*. Some readers may care to criticise or to re-word some of the proposed topics.

1. Professional ethics as touching the endorsement or sponsorship of organizations largely subsidized by commercial firms and either (1) openly acknowledged, or (2) not openly acknowledged.

2. Professional ethics in the public endorsement of a specified product—as in a radio talk.

3. Standards in the acceptance of health education material from commercial sources for (1) use with adults, (2) use with children, (3) as background material for the more or less discriminating classroom teacher.

4. Ethics and professional responsibilities in accepting membership on non-functioning committees, that is, where committee participation is merely nominal, the work of the committee being largely done for it without its members taking real responsibility in thinking out what is done or said.

5. How should the Public Health Education department of *American Journal of Public Health* handle publications issued by organizations largely subsidized by commercial firms, which fact is not openly acknowledged—with additional reference to such a combination when the organization advocates health practices, *not* scientifically accepted as true, but which further the business of the financial backers.

6. What procedures and what sources of authoritative help can be offered to health workers and to teachers for guidance in the selection of materials for adult or child teaching purposes?

7. What are some tests to be applied by public health workers when asked to serve on apparently ethical projects—such as a health exposition under commercial management—a new committee or other group for a public health purpose—and so on?

8. When may a health department or health association reproduce printed matter, radio talks, or other material already produced by another agency—what procedure should be followed—and what open acknowledgement of the source should be made?

9. What standards may be set up, on the basis of what we now know, by which a health worker may partially evaluate his health education methods and materials (that is, there are certain accepted elementary standards for reasonably good printed matter which might be set up for the printed matter of the health agency).

10. What is a public health education program? How is it different from a list or description of the activities or the materials used the past year or proposed for the coming year? In what way is the public health education program different from but a part of the program of public health activities, functions, services, or objectives of the health department or health association?

11. Is a united front or coöperative or co-ordinated or non-competitive health education program possible when there are two or more state-wide or city-wide health agencies, public and private, in a given territory? What are some of the recognizable difficulties? Should any one health agency in the state or city be accepted as the leader—and how should that leadership function?

12. Are private health agencies, in the effort to secure financial support, making unfair or unwise comparisons between the work of private and public agencies?

13. Are there any elementary tests which could be applied to our health education work in any of its phases or details?

14. When there is no staff member

specializing on health education—when, for example, it is stated to be the personal responsibility of the health officer—how under such circumstances will the health officer actually do health education—and *what* health education may he be expected to do?

15. Could we offer some tentative statements as to what skills or experience a man or woman should have, even when he is serving merely as a helper to the health officer who is credited with the doing of health education?

"They Do and They Don't"—So writes W. W. Bauer, Director of Bureau of Health and Public Instruction, American Medical Association.

They do and they don't. We have in our file a clipping from the *Chicago Tribune* for April 18, 1935, in which the word syphilis was not only mentioned, but headlined in connection with a meeting of the Illinois Social Hygiene Association. I am informed, though I do not have the clipping to verify, that the *Tribune* published an editorial on that subject in the same issue or perhaps a day or so later. In a clipping from the *Syracuse, N. Y., Post Standard*, March 27, 1932, entitled "Social Hygiene Vital Problem," syphilis is mentioned several times.

In the *Chicago Tribune*, April 28, 1935, appeared an article under the heading "Syphilis in U. S. on the Increase, Doctors Assert."

I am also in possession of radio talks dealing either with syphilis or gonorrhea which have been delivered over the following stations on behalf of medical societies. The figure in parentheses following the name of each station indicates the year in which the talk was broadcast:

WTIC, Hartford, Conn. (1931-32)
WBZ, Boston (1930-31-32)
WHAM, Rochester, N. Y. (1934)
WGY, Schenectady, N. Y. (1932)
WCAE, Pittsburgh (1934)
WBBM, Chicago (1930-32)
WJJD, Chicago (1931-32)
WGN, Chicago (1932)

In giving you this list I wish to assure you that I have no idea that it is complete, since there may be others; these are the ones of which I have definite knowledge.

Knoxville Has Heard about Syphilis—Health Officer Enneis, Knoxville, Tenn., sends a clipping from *Knoxville News-Sentinel*, dated June 6, 1935, with headlines as follows:

Syphilis heads list in number of cases here. Measles come second in contagious report and then follows gonorrhea.

Bureau urges sane view.

"Conspiracy of Silence" held responsible for failure to check ailments.

Then follows this news story:

More cases of syphilis were recorded at the City Health Bureau in 1933 and 1934 than any other communicable disease, according to a recently issued report.

Gonorrhea came third in the number of cases, exceeded slightly by measles.

"A combination of circumstances accounts for this condition, the most important of which has been termed 'the conspiracy of silence' regarding the disease," says the report in regard to syphilis. "It is frequently considered the result of one's own misconduct.

HALF ARE INNOCENT

"As a matter of fact almost half of the total cases are innocently acquired marital infections and congenital syphilis.

"Weapons are already available with which syphilis might be reduced from a major to a minor problem.

"Educational campaigns against syphilis and gonorrhea are too often met with rebuffs. To be attacked effectively these diseases must be brought out into the open, frankly discussed, and fearlessly fought."

HOUSEWIVES IN MAJORITY

A classification chart included in the report, shows that in the 2 year period, 75 housewives in the age group from 20 to 49 years had syphilis as compared with 53 prostitutes. The chart shows 62 had syphilis as compared with 53 cases among female servants.

The increase in syphilis is accounted for by treatment of transients by the clinic, treatment of infected women at Camp Home, and discovery of many cases during examination of food handlers.

Dr. Enneis writes:

A few years ago this same paper published a series of articles on syphilis and gonorrhea and one article that I have on file has a headline covering three columns, in which syphilis is mentioned. I have never heard of any adverse criticism locally on account of this kind of publicity.

HEALTH EDUCATION

The references below have appeared in *Library Index*, a weekly index to

current periodical literature in the field of public health, issued by National Health Library, 50 W. 50th St., New York, N. Y.

Armstrong, D. B., M.D. Can it now be told? *Journal of Health and Physical Education* (Ann Arbor, Mich.) 6:5-8, June, 1935.

Conrad, H. L. Historical steps in the development of health education. *Mind and Body* (New Ulm, Minn.) 42:79-81, May-June, 1935.

Whitney, A. W. Progress in safety education. *Nation's Schools* (Chicago) 15:33-35, June, 1935.

MAGAZINE ARTICLES

This department will welcome from readers criticisms of popular articles on health topics, whether listed under this heading or not. In view of the wide reading given to many such articles it seems important that we record valid objections to any of them.

"The Radio Nostrum Racket," by R. L. Strout. *Nation*, 20 Vesey St., New York, N. Y. July 17, 1935. 15 cents. "A startling exposure . . . before the Federal Communications Commission by Dr. Arthur J. Cramp, representing the American Medical Association."

"Shall It Be State Medicine?" by T. Swann Harding. *Christian Century*, 440 S. Dearborn St., Chicago, Ill. July 31, 1935. 15 cents. "State medicine now here"; "individualism within collective system" as now in France.

"Should Medicine Be Socialized?" by Dr. M. V. Leof. *Common Sense*, 315 4th Ave., New York, N. Y. Aug., 1935. 25 cents. Asking for full governmental control and professional autonomy.

"Specter of Paralysis Stalks Carolina." "Science has weapons for the battle with this year's poliomyelitis epidemics; new vaccines are undergoing their first critical tests." *Literary Digest*, 354 4th Ave., New York, N. Y. July 20, 1935. 10 cents.

REPORTS

Interesting is the fact that so many health department reports continue to be issued without table of contents or index, thus limiting their usefulness both to general readers, and to fellow health officials and research workers.

The 20th annual report of Department of Health for La Salle, Peru, and Oglesby, at La Salle, Ill., devotes nearly two pages to the record of what "Coöperating Agencies," including organizations, professional groups, and others, have been doing for public health in those communities.

FOR EDUCATION OR REFERENCE

Usually state and local health agencies will supply sample copies of their materials to health workers, but never expect them to send free copies for distribution outside of their respective territories.

Better times and the birth rate; appendicitis and hospital facilities; the comparability of cancer death rates; health record for May, 1935. In *Statistical Bulletin*, Metropolitan Life Insurance Co., New York. June, 1935.

"Children's Bureau and Other Publications Relating to Children." Supt. of Documents, Washington, D. C. Free. List of publications for sale.

"Conservation of School Children's Eyes," by Dr. A. C. Snell. Reprint. Rochester and Monroe County Committee on Eye Conservation, Room 304, 277 Alexander St., Rochester, N. Y. Originally a radio talk.

"Healthy Hearts" is a reprint from *Hygeia* of 4 articles; 16 large pages; 10 illustrations. American Medical Assn., 535 N. Dearborn St., Chicago. 15 cents; less for 25 or more copies.

"The Health-Protection Aspects of Convention Planning and Operation: Selecting the Convention City: Some Precautions to Observe," by H. N. Calver. *World Convention Dates*. 333 W. 42d St., New York. May, 1935.

"Highlights from the Nation's Accident Experience in 1934." Press material on traffic, occupational, public, and home accidents. National Safety Council, 20 N. Wacker Drive, Chicago. *Free.*

"A Project in Rural School Health Education," by R. E. Grout. Home-School Relationships. Milbank Memorial Fund, 40 Wall St., New York. A reprint.

American Social Hygiene Assn., 50 W. 50th St., New York, offers new folders: "Syphilis," "Gonorrhea," "For Expectant Mothers," "The Truth About Syphilis and Gonorrhea," and "The Medical Charlatan" (exploiter of the sick, well, ignorant, credulous). *\$1.00 per 100; \$5.00 per 1,000.*

Massachusetts Dept. of Health, Boston, has issued:

I Don't Want Diphtheria (4-page folder).
What's and Why's of Cancer (8 pages).
For Your Teeth and Gums (leaflet on diet).
The Care of Your Teeth (2-page leaflet).
Healthful Living for the Teens (4 pages).
A Message to Dog Owners (a slip urging antirabic injections).

Agencies Supplying Health Bulletins, Leaflets, Posters, Films (5 mimeographed pages).

TIMELY TOPICS

The Department of Agriculture, Washington, D. C., and most state agricultural colleges will supply material on pressure canning which seems to have increased importance these years when many more people are canning fruits and vegetables. The Bureau of Home Economics recently announced that

Modern canning science says in no uncertain terms, "You can process fruits and tomatoes in the boiling water bath but you *must* can nonacid vegetables under steam pressure if you want wholesome products that will keep."

See also "Proper Processes for Home Canning," by F. W. Tanner. *J.A.M.A.* May, 1935.

Insurance companies and other safety centers issue pamphlets and placards on the prone pressure method of resuscitation from electric shock, drowning, or asphyxiation. Thus the use of this material is timely all the year round.

"Diving Helmets Are Dangerous Toys," by F. C. Mills. *Scouting*, 2 Park Ave., New York, N. Y. July, 1935. *15 cents.* A new summer safety hazard, and what to do about it.

BOOKS AND REPORTS

French Medicine—By *M. Laignel-Lavastine* and *M. Raymond Molinery*. Translated by *E. B. Krumbhaar*, M.D. New York: Hoeber, 1935. 168 pp. Price, \$2.50.

This interesting book is another of "A Series of Primers in the History of Medicine" under the general title, "Clio Medica." Written by Frenchmen, it has been translated and edited by Dr. Krumbhaar, who has done an excellent piece of work and given a number of informative notes.

An introduction gives a short outline of what will follow; then comes the description of the first civilizing wave in Gaul, which began on the shores of the Mediterranean as a development of Phoenician, Aegean and Greek civilization, and carried matters from curative magic to the Gallo-Roman development. The Christian religion fostered curative magic to the detriment of scientific medicine. Indeed, the Church recognized the diabolic or malefic origin of certain diseases which must be exorcised. In the Gallo-Roman period which followed, the Hippocratic writings were carried throughout the Greco-Roman civilization by the power of the Roman Empire. This period was made notable by the birth of Galen in the 2nd century, A.D.

Public hygiene made astonishing advances. Ancient Rome had 14 aqueducts carrying water into the city. There were more than 800 public and private baths, and through the wars of conquest there was brought about the widespread establishment of thermal resorts. The development of military medicine in this period was remarkable, and the discovery of military

hospitals shows that the sanitary service was well done even in the provinces.

There developed specialists such as oculists, otologists, dentists, gynecologists and fistula specialists. The authors feel that it is depressing that such a marvelous civilization, whose hygienic legislation has not been equaled in 20 centuries, should have been annihilated by the invasion of barbarians, and hold that the new wave of Western civilization has not yet acquired an equal perfection in certain directions.

In the third chapter we have a description of the beginning of French medicine from Clovis (465–511 A.D.) to Charles VIII (1470–1498). During this period there was a great development of hospitals brought about by the fight against leprosy on the one hand, and the application of the parable of the Good Samaritan on the other. The first French hospitals were erected along the pilgrimage routes. There are bad reports concerning the hygiene of some of these hospitals, but the authors defend many of them against the attack, and point out that at the Hôtel Dieu of Paris, 1,300 brooms were used up annually. By the 16th century the hospitals for lepers which had played such a large rôle, had very few lepers, as the disease had become rare, and in 1543, Francis I ordered the segregation of the lepers at the leper hospitals of the kingdom.

With the invasion of the barbarian hordes who destroyed the Roman Empire, civilization found refuge in the monasteries, which hastened the advance of science, but the inroads of so-called religion which became superstition, did much to hold back the scientific development of medicine.

Successive Councils forbade the clergy to spill blood, and thus brought about the separation of medicine and surgery. They decreed the incompatibility of medicine and religion, which, combined with the obligation of celibacy, turned away many pupils.

In the Middle Ages medical instruction was largely clerical, many doctors having been at first theologians. There were monks who concerned themselves with bookish medicine because they met with it in the manuscripts they read.

The School of Montpellier was founded about 738 and resembled the School of Salerno, the influence of which was noteworthy for the introduction of the lay spirit into medieval medicine. Medicine was taught at Paris in 1180. The library of the Faculty of the school in Paris was founded in 1391, and up to 1555 many gifts and purchases are recorded. Unfortunately a long decadent period began about this time which was only cleared up with the Renaissance. The faculties of Bordeaux, Lyons, Strasbourg, Nancy, Lille, Algiers, and Marseilles are described separately.

The history of the Renaissance is particularly interesting. Rabelais is given the most prominent place in medicine and Ambroise Paré in surgery, though he was far more than merely a surgeon. The further history of medicine in France is taken up by centuries, and sketches of many of the men who have made medical history are given, with illustrations.

We wish it were possible to give a longer review of this delightful work, but it must be read to be appreciated. It is well printed and has few mistakes. However, on page 2, second paragraph, Chapter II is referred to twice, whereas the second reference should be to Chapter III. We would suggest also that the dates should uniformly be given along with names. For example, Chapter III covers from "Clovis to

Charles VIII," but we suspect that many, even historians, will not be able to give off-hand the date of either of these men.

Altogether the book is heartily recommended. MAZŮCK P. RAVENEL

Emotions and Bodily Changes—By H. Flanders Dunbar, M.D., Ph.D. New York: Columbia University Press, 1935. 595 pp. Price, \$5.00.

In this carefully indexed volume, with its bibliography of 2,251 titles topically arranged, Dr. Dunbar not only presents an invaluable survey of the literature on psychosomatic relationships published in the years 1910 to 1933; she interprets the trends of medical and psychological thought in a manner which makes the book of vital importance to everyone concerned with the many phases of the problem of maintaining and restoring health.

The book is divided into three parts dealing, respectively, with orientation and methodology, comprising problems of integration and differentiation, problems of acute and chronic illness, and problems of measurement; organs and organ systems, devoting one chapter to general considerations and eleven chapters each to a specific system; and therapeutic considerations and concluding remarks.

Space permits only a summary of the general conclusions. Dr. Dunbar finds that the organismal theory, elaborated especially during the last 20 years, in biology and medical sciences (involving a new concept of the organism-environment equilibrium) is fundamental to an understanding of disease processes and is remodeling our definitions of health and disease. This general truth now needs specific factual elaboration in support of the idea of the importance of the organism as a whole, or the organism-environment as a whole. The public health official, the specialist, and the general practitioner who fails to

grasp and utilize this new concept is out of step with medical progress.

"Practically," says the author, "in the maintenance of health, we are coming more and more to realize the necessity for coöperation between physicians, especially those engaged in preventive medicine and public health activities, and specialists in the various aspects of our social organization—educators, clergymen, leaders in industry, etc."

FREDERICK W. BROWN

Science and the Public Mind—By Benjamin C. Gruenberg, with a foreword by John C. Merriam, President, Carnegie Institution of Washington. New York: McGraw-Hill, 1935. 196 pp. Price, \$2.00.

This book is an account of an investigation made by the author into the place of science in relation to adult education and how activities in that field should be stimulated.

It is explained at the outset that "The book represents the interaction of many minds called upon to think aloud on various aspects of the relationships between that vague entity called 'science' and that perhaps even more vague something known as 'the public.'" In preparation for it there were interviews or conferences with some two hundred educators, scientists, publicists, "and a great deal of correspondence with others," including administrators of educational and other institutions. A grant was made by the Carnegie Corporation of New York to meet the cost of the study.

The volume is divided into 3 parts containing in all 16 short chapters with many subdivisions. The first part discusses the place of science in modern life, regarded from the standpoints of the individual's interests, civic and social interests, and our common or cultural interests.

The second part discusses how science can be brought to the public,

including the teacher, the lecturer, the newspapers, radio, and moving pictures.

Part three, called "The Educational Situation," has to do with such topics as the public's changing interests, the failure of science to reach the public, and a summary of findings and recommendations.

In his foreword, Dr. Merriam gives a strong reason for promoting science as a method of thought and a mode of life. He says:

In this connection it is important to note that whatever the ultimate fate of government by the people, the highest success in a system of that type can be attained only by development of a citizenry thinking continuously and effectively according to a pattern which is fundamental in science, namely, one which involves wide and clear vision, recognition of need for continuous inquiry upon great questions, and the settlement of problems on the basis of facts and logic.

Dr. Gruenberg points out that in the last 75 years science has completely changed its place in our common thought. Formerly a great mystery in the hands of a few, science has become—

. . . a dynamic process of scrutiny and research that attacks and transforms every phase of thought and practice. The men and women who make up the active adults of our population must attend to science in one or another of its many aspects, whether they wish or not. And they do.

It is hard to understand how Dr. Gruenberg could have written a book so full of the opinions of so many people on so many details of his subject, and that he has done so well is a tribute to an editorial zeal which must be regarded as remarkable.

The book is written in a clear, crisp and highly condensed style. This is the ninth volume which Dr. Gruenberg has produced on biological or educational topics, not to speak of several of which he has been co-author or editor. He has long been favorably known in public health activities. GEORGE A. SOPER

Essentials of Feeding and Paediatric Practice—By *Henry P. Wright, B.A., M.D.* New York: Oxford University Press, 1934. 212 pp. Price, \$4.25.

According to the preface, this book is intended to serve the needs of the trained nurse, the student of medicine, and the busy general practitioner. It will undoubtedly be useful to all three. The title is too inclusive: pediatric practice is a pretty large field. The most significant part of the book is that devoted to the nutrition of the infant.

A few criticisms occur to one as he glances over the chapters. The balance could be improved. The chapter on clinical and laboratory tests could largely be eliminated; the tests described are not done by the average general practitioner and anyone doing them would naturally turn to larger and more complete special volumes. The chapter on physiology tries to compress too much into too small a space. The chapter on "Rules for Isolation and Exclusion of School Children in Cases of Common Communicable Diseases" is not well advised since the matter of isolation and quarantine is under the control of the board of health, not the general practitioner, and the official rules in any given community may vary widely from those given in this book.

The chapter on therapeutics ought to prove useful for quick reference. There are a good index and several valuable tables, and the printing is good.

This is a useful little book to have on the shelf—along with others.

MERRILL E. CHAMPION

Blood Groups and Blood Transfusion—By *Alexander S. Wiener, M.D.* Springfield, Ill.: Charles C. Thomas, 1935. 220 pp. Price, \$4.00.

One is tempted to refer to this work as a compend of information on the

individuality of the blood for the physician and serologist. The author has adequately considered the historical, practical, medico-legal, genetic, and anthropological aspects of the subject. The importance of using the *International Classification* of blood groups is correctly emphasized. The constitution of and methods for the identification of the four major blood groups as well as the subgroups of groups A and AB, and of the less easily demonstrable groups M, N, and MN, and the little known anomalous groups, are given. The sources of error in the determination of blood groups, the indications and technic of blood transfusions are discussed.

Some fundamental yet elementary principles of genetics and biometrics as applied to the hereditary transmission and frequency of blood groups are given. In view of recent legal recognition of the use of blood grouping as a means of determining parentage, these considerations are especially valuable and opportune.

The book is well written and printed. Numerous references to original literature are included. The material is presented in a very logical and concise manner, although the author assumes that the reader is familiar with the general principles involved in the determination of the blood groups. This book is to be recommended to anyone desiring a concise and authentic statement of facts in regard to our knowledge of the individuality of the blood.

NEWELL R. ZIEGLER

Lactobacillus Acidophilus and Its Therapeutic Application—By *Leo F. Rettger, Maurice N. Levy, M.D., et al.* New Haven: Yale University Press, 1935. 203 pp. Price, \$2.50.

A large part of this book is devoted to the use of acidophilus as a therapeutic agent, and as this is out of the

sphere to which the *Journal* is devoted, it will not be reviewed critically.

Approximately 50 pages are given to the history and bacteriology of the *Lactobacillus* genus. This is largely straight bacteriology, but clinicians and bacteriologists alike will find the discussions useful and interesting. The chapter which deals with the oral and dental types of *Lactobacilli* is especially so in view of the findings of Bunting and others.

For upward of 20 years studies on the intestinal flora have been going on at Yale. The present volume covers the studies of the past 4 years.

The printing and binding are excellent and the entire volume is of such interest that it will well repay the reader for the time spent on it.

MAZŮCK P. RAVENEL

The Malden Health Series (rev. ed.)
New York: Heath, 1935.

The Voyage of Growing Up—By Clair E. Turner, Dr.P.H., and Grace T. Hallock. 204 pp. Price, \$.60.

In Training for Health—By Clair E. Turner, Dr.P.H., and Jeanie M. Pinckney. 152 pp. Price, \$.60.

Community Health—By Clair E. Turner, Dr.P.H., and Georgie B. Collins. 250 pp. Price, \$.84.

Physiology and Health—By Clair E. Turner, Dr.P.H. 278 pp. Price, \$.96.

These books, so carefully written and edited, which since their first appearance in 1928–1929 have been popular as supplementary readers and textbooks, have come out in new dress in the revised editions. The make-up of the books is essentially the same except for several new and additional illustrations in each volume and the gay covers which will brighten up any long shelf of school books. A few chapter headings have been changed. For in-

stance, in *Community Health* the new title of Chapter I, "Planning Your Health Program," is much more pertinent to the young reader than the abstract title, "Health." The revision of Chapter I also brings this book up to date in child health education content and procedures. The volume, too, has been revised to relate closely with the social science studies that have been introduced into the curriculum.

In the volume, *The Voyage of Growing Up*, a chapter on safety has been included. The revised treatment of the chapters on teeth and digestion are more consistent with the educational trend of teaching children facts as realities and not dressing them up by analogies.

In revising *Physiology and Health* the editors have done a commendable bit of work in transferring the experiments and activities bearing on the subject from the end to the beginning of each chapter.

ANNA B. TOWSE

What About Alcohol?—By Emil Bogen, M.D., and Lehman W. S. Hisey. Preface by Haven Emerson, M.D. Los Angeles: Angelus Press, 1934. 105 pp. Price, \$1.50.

The introduction of this book states clearly the requisitions of such a work—the material must be truthful: scientific accuracy and reliability are important; the facts not only correct but simply and clearly told and in such a manner as to excite the interest of the reader.

The authors have given a useful book profusely and excellently illustrated, especially for the young. While they have adhered to facts they are often stated in an exaggerated form, and a number of impressions which can never be proved, and are actually not true, are given; for example, "But the person who drinks alcohol becomes as a result a worry to all of the people with whom he comes in contact"; ". . . as a person becomes more

and more used to alcohol he is apt to want it more and more . . ."; and other similar statements. One cannot but remember that in many countries, France, Italy, and Germany particularly, the use of wine and beer is habitual with the vast majority of the population, yet these countries produce much that is best in science, literature, and art. The English, who are competent handlers of stronger alcoholic beverages, control the largest empire in the world and conduct its affairs with signal ability and success.

Millions of people use alcohol in moderation throughout their lives without the dire results intimated or threatened, and some of the most famous physiologists have held that the paralysis of the higher functions pictured on page 56 is a distinct physiological rest which is beneficial to the subject.

In spite of these faults, the book is one of the best of its class. It ends with an extensive bibliography for those who wish to pursue the subject further.

MAZÛCK P. RAVENEL.

A College Textbook of Hygiene—
By Dean F. Smiley and Adrian G. Gould (rev. ed.). New York: Macmillan, 1934. 383 pp. Price, \$2.00.

This revision of a work which first appeared in 1928, consists largely in material changes of the first section, and the effort to modernize certain chapters.

In most chapters the revision is very slight, even as regards the bibliographies at the ends of chapters.

The content is divided into an introductory section touching upon heredity, bacteria and disease, and infection, one on prevention of disease, and sections on the various systems of the body, respiratory, digestive, nervous, endocrine, muscular, excretory, circulatory, genital, and special senses.

An attractive text—but rather elementary for college students. If interest is to be maintained, the student must have something into which to set his intellectual teeth.

CHARLES H. KEENE

New and Nonofficial Remedies, 1935
—Containing Descriptions of the Articles Which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1935. Chicago: American Medical Association, 1935. Cloth. 510 pp. Price, \$1.50.

In this book the Council on Pharmacy and Chemistry lists and describes the medicinal preparations that it has found acceptable for general use by the medical profession. A glance at the list of the Council members and the long list of consultants appearing in the first part of the book gives ample warrant for the authority of the Council's selections.

A valuable feature of the book is the grouping of preparations in classes. Each of these is introduced by a general discussion of the group. Thus the silver preparations, the iodine preparations, the arsenic preparations, the animal organ preparations and the biologic products are each preceded by a general discussion of the particular group. These general articles compare the value of the products included in the group with similar pharmacopeial and other established drugs which it is proposed that these proprietary preparations shall supplement or supplant.

Physicians who wish to know why a given proprietary is not described in New and Nonofficial Remedies will find the "Bibliographical Index to Proprietary and Unofficial Articles not Included in N. N. R." of much value. In this section (in the back of the book) are given references to published articles dealing with preparations that have not been accepted. These include references

to the Reports of the Council, to Reports of the A. M. A. Chemical Laboratory and to articles that have appeared in *J.A.M.A.*

A. M. A. COUNCIL

Diet and Like It—By *Mabel E. Baldwin, Ph.D.* New York: *Appleton-Century*, 1935. 230 pp. Price, \$2.50.

This is a detailed exposition of meal planning for those who wish to lose weight, and for those who do not wish to gain weight.

Part I, pp. 7-112, is devoted to menus, which offer a wide selection of nutritious and protective foods. The caloric value of each standard portion is given, and the amounts to be consumed are stated as precisely as is practicable. There is no doubt that faithful adherence to the directions will be accompanied by reduction in body weight. It should be pointed out that there are schools of thought in dietetics, as in other branches of physiology. The menus that have been assembled are entirely orthodox but they are of the low protein-vegetable type. Those who belong to the high protein school will find it necessary to modify the diets somewhat.

Part II was prepared for those who find it necessary to guard against gaining weight, and for those who are looking for guidance in methods that are safe and effective. The chapter headings, somewhat condensed, are: Body Weight, Food and Body Weight, Protective Diets, Proteins, Fats, Carbohydrates, Minerals, Vitamins, Roughage, Planning a Protective Diet, Selection of Food, and an Appendix of Numerical Values of Food Factors. The treatment is non-technical, and for all practical purposes it is satisfactory.

This book is well adapted to the readers for which it was prepared, and dietitians will find it useful for reference.

A. G. HOGAN

Guiding Your Child through the Formative Years—By *Winifred de Kok, M.R.C.S., L.R.C.P.* New York: *Emerson Books Inc.*, 1935. 192 pp. Price, \$2.00.

An eminently readable and level-headed book is this small volume on the bringing-up of the young child. The author is a physician and herself the mother of two children whose development serves to illustrate the points she wishes to make. Nineteen chapters furnish an opportunity for wise advice on such varied topics as Weaning, Excretion, the Perfect Routine, Learning to Talk, Fears and Fancies, Sex Education, Infantile Habits, Freedom and many others.

Learned and technical discussions are, quite properly of course, conspicuously absent from this book which is evidently intended for the use of mothers; yet the background of thorough familiarity with all the modern scientific ideas concerning child care is evident in every chapter.

Some mothers may be a bit taken aback at the matter-of-fact way in which the subjects of sex and of elimination are treated but the simplicity and sincerity of it are obvious throughout; the child's point of view is fully grasped and that in itself makes for sincerity. MERRILL E. CHAMPION

Mental Hygiene for Effective Living—By *Edwin A. Kirkpatrick.* New York: *Appleton-Century*. 1934. 387 pp. Price, \$3.00.

Addressing himself to beginning students of Mental Hygiene, the author says in his Preface that he has gathered facts and truths from the fields of "anthropology, physiology, sociology, psychology, child study and education," that he has attempted to "temper them with common sense . . . to present the characteristics of normal functioning, and to show how variations from the normal are produced." The ma-

terial appears to have been selected on the basis of its popular appeal and practical application to the situations of everyday living, and is presented in a style both interesting and clear.

The author's approach to deviations in development and behavior through an understanding of the normal is, in itself, commendable. Throughout the book, however, there runs the tendency to overemphasize the ease with which the principles of mental hygiene may be applied to the solution of the student's own problems and to those of others whom he would help. The student, with little if any background, is advised to try out these principles on himself and his friends. This point of view runs counter to one of the most salient facts derived from the experience of the trained social worker, the psychologist, and the psychiatrist, namely, that the successful practice of mental hygiene is an art requiring a much more thorough background than can be gained from the reading of a single volume or the pursuit of a course of lectures.

In view of the author's purpose to familiarize the uninitiated with the meaning of mental hygiene it seems strange that he fails to mention the mental hygiene movement, as such, or the name of its founder, Clifford W. Beers, whose personal experiences and zeal on behalf of the mentally afflicted form the source from which have sprung the mental hygiene activities of the past 25 years. FREDERICK W. BROWN

Twelve Hours of Hygiene—By F. L. Meredith, M.D. Philadelphia: Blakiston, 1935. 364 pp. Price, \$1.90.

The design of this book, as stated in the Preface, is to fill a need for "one-hour-one-semester courses in hygiene for college freshmen."

We like the plan of the book very much. The chapters follow in logical sequence and cover pretty nearly every-

thing that need be given in an elementary course to freshmen. Indeed we suspect that for the average freshman some of the material is far beyond his comprehension, even though we acknowledge his need of it. For example, Chapter I contains 45 pages, under two heads, A and B—A, General Considerations, 19 pages, and B, The Ten Systems, 26 pages, either one of which is more than enough for a lesson for the average student. The same may be said for several other chapters, especially those which discuss difficult subjects such as Chapter XII, Reproduction and Sex.

There are 7 appendices, taken from well known authorities, giving the chemical composition of food materials, the phosphorus, calcium and iron content, 100-calorie portions, height-weight-age averages, etc., all of which are useful and well put.

The reviewer doubts the value of a book of this type for the purpose designated, and considers the title unfortunate. It is a good book for ready reference; the material is sound and well authenticated; and an abundance of common sense is in evidence. Each sub-title is put in the form of a question.

The book is well printed and bound, and we trust will accomplish its purpose. MAZÛCK P. RAVENEL

Laboratory Manual of the Department of Bacteriology and Immunology, Peiping Union Medical College—Prepared under the direction of C. E. Lim. 2nd ed. Peiping, China, 1935. 182 pp. Price, \$1.50.

This is an excellent book prepared for the guidance of students and staff members. There are some features which deserve special mention. Twenty-seven pages are given to the consideration of laboratory animals and their care. This contains a useful chart giving the normal differential blood

count of all animals and one bird most likely to be used in laboratory work.

There is also a section on the examination for pathogenic fungi.

The work is well documented, in addition to which 3 pages are given to a list of reading references. It is well printed and clearly written, but unfortunately there are some errors apparently due to the printer's unfamiliarity with English; for example, on page 49, we find "paper" instead of "appear"; on page 134, "peritoneum" instead of "peritoneal"; on page 150, "altual" instead of "actual."

The book contains a great amount of valuable material well condensed, and is up to date. The only omission detected concerns the H and O agglutination. This little work can be thoroughly commended. MAZÛCK P. RAVENEL

Dysentery in Denmark: A Contribution to the Bacteriology and Epidemiology of Infection with Sonne and Flexner Bacilli—By Knud Bojlen. Copenhagen: Bianco Lunos Bogtrykkeri A/S, 1934.

These investigations were carried out in the State Serum Institute at Copenhagen under the direction of Dr. Th. Madsen during the years 1926–1933, and are here reported in English.

After giving a comprehensive review of the literature on dysentery bacilli, the author presents the results of his own studies based upon 1,786 Sonne and 1,206 Flexner cultures obtained from more than 1,000 patients. While he found the Sonne bacilli to be serologically uniform, he was able to subdivide the newly isolated strains into 6 sub-groups on the basis of their

fermentation of certain sugars. In like manner, granting that the Flexner group contains several well defined serological types with mutually differing antigen-mosaic, he found that independently they may be divided into 10 sub-groups on the basis of their fermentation reactions. Although certain of these fermentation reactions may vary after sub-culture, he maintains that they are epidemiologically constant. Hence the biochemical subdivision is useful in tracing sources and contacts.

In the epidemiological section the author first gives a review of the literature on Institutional ("Asylum") Dysentery, and then reports his own observations. These include studies carried on continuously from June, 1927, to January, 1933, in Ebberodgaard Asylum for the feeble-minded, more limited studies in certain other Danish institutions, a number of house epidemics in various parts of the country, 2 milk-borne epidemics, and an intensive investigation of dysentery in a limited rural community carried on over a period of 3 years. He concludes this section with a general summary of the epidemiology of dysentery in Denmark, and a discussion of the factors involved in its maintenance and spread. On the basis of these studies, inferences are drawn with regard to the control of the disease.

This is a careful and thorough piece of work. It is undoubtedly one of the most important contributions to this subject made in recent years. It contains an excellent list of references bringing the bibliography up to date.

KENNETH F. MAXCY

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Of Human Liberty—Milk-borne epidemics totalling 40 with 1,324 cases and 44 deaths is the 1934 price we paid for the privilege of drinking raw milk. Typhoid fever ranked first in number of epidemics, but septic sore throat was far in the lead in numbers of cases affected.

CRUMBINE, S. J. Milk-Borne Epidemic Diseases in the United States and Canada. *Child H. Bull.* 11, 4:113 (July), 1935.

What's New About Flu—Interpandemic influenza, at least, is caused by a filtrable virus transmissible to mice and ferrets. The picture produced in the experimental animals may serve to distinguish the disease from related respiratory infections.

FRANCIS, T. Recent Advances in the Study of Influenza. *J.A.M.A.* 105, 4:251 (July 27), 1935.

Differentiating the Streptococci—Reasons for considering scarlet fever and erysipelas as distinct clinically and etiologically, each being caused by its own streptococcus, are convincingly set forth.

HEKTOEN, L. The Specificness of Certain Hemolytic Streptococci. *J.A.M.A.* 105, 1:1 (July 6), 1935.

Heat Sources and the Nose—After Leonard Hill stated originally that heat rays from dull surfaces tended to close the nostrils, whereas rays from luminous sources were "nose-openers," American and other researchers denied the claim and described the methods by which they came to the opposite conclusion. In this paper. Dr. Hill questions their researches and reasserts his original findings.

HILL, L. Nose-Opening Rays. *Am. J. Hyg.* 22, 1:183 (July), 1935.

More about Phage—Bacteriophage can be extracted from aqueous solutions by ether, and when partly removed, the residual phage may be restored in potency by transfer. In a second paper is described the preparation of a lytic filtrate (artificial bacteriophage) by incubating bacterial cultures, autoclaving, incubating again, and oxidizing with hydrogen peroxide.

LEMAR, J. D., and MYERS, J. T. Studies on the Nature of Bacteriophage. *J. Infect. Dis.* 57, 1:1 (July-Aug.), 1935.

Etiologic Factors in Heart Disease—In Chicago, 1,000 cases of heart disease were studied to determine the frequency of the various types. While most cases are readily classifiable, there are many difficulties, and the conclusion is stressed that each case is a highly individual problem with many issues to be considered.

MAHER, C. C., *et al.* Heart Disease in the Chicago Area. *J.A.M.A.* 105, 4:263 (July 27), 1935.

Blood Sugar and Nicotine—The "lift," so widely attributed to smoking in the latest cigarette advertising, is in reality a handicap which outraged Nature tries her best to counteract; this is the conclusion of an interesting study.

McCORMICK, W. J. The Rôle of Glycemic Response to Nicotine. *Am. J. Hyg.* 22, 1:214 (July), 1935.

Applying Mathematics to Health—This discussion of the necessity of applying statistical methods to clinical observation applies with equal force

to questions of public health administration. It is a paper which all would do well to take to heart.

MITCHELL, A. G. Critical Interpretation of Clinical Observations. J.A.M.A. 105, 4:241 (July 27), 1935.

Down to Brass Tacks in Tuberculosis—In this frank and wholesome discussion of the limitations of tuberculosis prevention, the term "relaxation" instead of the gruesome "collapse" therapy is proposed. Practical possibilities in providing opportunities for discharged cases is the main theme of the paper.

VARRIER-JONES, P. A General Survey of the Tuberculosis Problem. J. State Med. 43, 7:392 (July), 1935.

Depression Decline in Rhode Island Mortality—Contains a fairly complete set of tables. The greatest percentage declines were found at the younger ages, and in the infectious diseases, intoxications, nervous, and respiratory diseases. Increases were found for cancer, rheumatic and circulatory disease rates.

ROUND, LESTER A. Reprint from the Rhode Island Registration Report, 1935.

BOOKS RECEIVED

VITALITY. A BOOK ON HEALTH FOR WOMEN AND CHILDREN. By Elizabeth Sloan Chesser. New York: Oxford, 1935. 254 pp. Price, \$2.50.

HEALTH PROTECTION IN THE U.S.S.R. By N. A. Semashko. New York: Putnam, 1935. 176 pp. Price, \$1.75.

KNOW THYSELF. A STUDY IN MENTAL QUALITIES. By John Fox. Philadelphia: Dorrance, 1935. 267 pp. Price, \$3.00.

MENTAL HEALTH. ITS PRINCIPLES AND PRACTICE. By Frank E. Howard and Frederick L. Patry. New York: Harper, 1935. 551 pp. Price, \$3.50.

HOME RULE FOR METROPOLITAN CHICAGO. By Labert Lepawsky. Chicago: University of Chicago Press, 1935. 210 pp. Price, Cloth, \$2.00; Paper, \$.50.

THE HUMAN MACHINE. ITS USES AND ABUSES. By Lorena M. Breed. Boston: Stratford, 1934. 101 pp. Price, \$1.50.

THINKING ABOUT MARRIAGE. By Roy A. Burkhardt. New York: Association Press, 1934. 156 pp. Price, Paper, \$1.00; Cloth, \$1.75.

GYNECOLOGICAL AND OBSTETRICAL TUBERCULOSIS. By Edwin M. Jameson. Philadelphia: Lea & Febiger, 1935. 256 pp. Price, \$3.50.

LIVING ALONG WITH HEART DISEASE. By Louis Levin. New York: Macmillan, 1935. 126 pp. Price, \$1.50.

MEDICINE IN THE MIDDLE AGES. By David Riesman. New York: Hoeber, 1935. 402 pp. Price, \$5.00.

THE NEW HEALTHY LIVING. Two Book Series. By C.-E. A. Winslow and Mary L.

Hahn. New York: Merrill, 1935. Book I, 332 pp. Price, \$.84. Book II, 460 pp. Price, \$1.00.

FIFTY YEARS IN PUBLIC HEALTH. By Sir Arthur Newsholme. London: George Allen & Unwin, 1935. 415 pp. Price, \$5.00.

ESSENTIALS OF FIELD SANITATION. FOR THE MEDICAL DEPARTMENT, UNITED STATES ARMY. Revised edition. Prepared by Department of Preventive Medicine, Medical Field Service School, Carlisle Barracks, Carlisle, Pa. 1935. 180 pp. Price, \$.25.

LEWIS' NEW AIR CONDITIONING FOR COMFORT. By Samuel R. Lewis. 2d ed. Chicago: Keeney Publishing Co., 1935. 277 pp. Price, \$2.50.

PERSONAL AND COMMUNITY HEALTH. 4th ed. Clair Elsmere Turner. St. Louis: Mosby, 1935. 680 pp. Price, \$3.00.

LABORATORY MANUAL OF THE DEPARTMENT OF BACTERIOLOGY AND IMMUNOLOGY, PEIPING UNION MEDICAL COLLEGE. (2nd ed.) Prepared under the direction of C. E. Lim. 1935. Peiping, China. 182 pp. Price, \$1.50.

NEW AND NONOFFICIAL REMEDIES, 1935. Articles which stand accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1935. Chicago: American Medical Association, 1935. 510 pp. Price, \$1.50.

DYSENTERY IN DENMARK: A Contribution to the Bacteriology and Epidemiology of Infection with Sonne and Flexner Bacilli. By Knud Bojlen. Copenhagen: Bianco Lunos Bogtrykkeri A/S, 1934.

* To Chicago only

A WORD TO THE THRIFTY

VERY few of us, at any time, will entirely disregard an opportunity to reap a financial benefit from thrifty buying or from careful and calculated investments. Why, then, do A.P.H.A. Fellows continue to overlook the gain inherent in Life Membership? They should do so no longer.

A careful study of the chart on the opposite page will reveal the savings which will accrue to Fellows by taking Life Membership at various ages. For example, a Fellow applying for Life Membership at the age of 40 will save a little over \$75. This saving (three-quarters of the cost of Life Membership) is of such proportion as to warrant careful investigation.

Beside the straight economical benefits, others accrue to Life Members: (1) annual payment of bills is onerous to some—Life Membership eliminates that; (2) in times of low income, a Life Member is assured of his continuation in the Association, thereby safeguard-

ing for all time his professional standing; (3) a Life Member can pride himself on the high type of professional spirit he has shown by investing in the future of public health work.

Life Membership dues need not be paid at once—the payments may be spread over a year from the date of election, which takes place at each Annual Meeting.

Some may ask—What is done with the dues of Life Members? They are set up in a Life Membership Fund entirely separate from other Association funds, and only the interest therefrom is used to carry the cost of each Life Member's participation in Association activities.

It must be obvious that the advantages of Life Membership far outweigh the disadvantages. The Committee on Fellowship and Membership, therefore, urges each and every Fellow to give serious thought to the desirability of applying for Life Membership.

APPLICANTS FOR FELLOWSHIP

IN accordance with the By-laws of the Association, the names of applicants for Fellowship are officially published herewith. They have requested affiliation with the Sections indicated. Action by the various Section Councils, the Committee on Fellowship and Membership, and the Governing Council will take place between now and the Milwaukee Annual Meeting.

HEALTH OFFICERS SECTION

P. J. Crawford, M.D., C.P.H., Ancon, C. Z. Cornelius A. Harper, M.D., Madison, Wis. James A. Hayne, M.D., Columbia, S. C. Leopold M. Rohr, M.D., Jamaica, N. Y. John J. Sutter, M.D., Lima, O. William C. Williams, M.D., C.P.H., Nashville, Tenn.

LABORATORY SECTION

Clarence N. Boynton, M.A., Phoenix, Ariz. George J. Hucker, Ph.D., Geneva, N. Y. Benjamin S. Levine, Ph.D., Chicago, Ill. Kathryn R. Tirrell, B.A., Bridgeport, Conn.

VITAL STATISTICS SECTION

Marjorie Bellows, A.B., White Plains, N. Y. Thomas J. Duffield, B.S., New York, N. Y. Louis Weiner, E.E., New York, N. Y.

PUBLIC HEALTH ENGINEERING SECTION

Elmer W. Campbell, D.P.H., Hallowell, Me. M. Warren Cowles, B.S., Ridgewood, N. J. John R. Hoy, B. Chem., Jacksonville, Fla. Charles E. Trowbridge, B.S. in S.E., New York, N. Y. Arthur D. Weston, Newton, Mass.

INDUSTRIAL HYGIENE SECTION

Theode Saint-Martin, M.D., D.P.H., Noranda, Que.

CHILD HYGIENE SECTION

C. M. Derryberry, Ph.D., New York, N. Y.

PUBLIC HEALTH EDUCATION SECTION

Midian O. Bousfield, M.D., Chicago, Ill.
J. Clarence Funk, LL.B., Harrisburg, Pa.
Marie F. Kirwan, New York, N. Y.

Daniel G. Gill, M.B., D.P.H., Montgomery, Ala.

Jacques P. Gray, M.D., M.P.H., San Francisco, Calif.

Benjamin G. Horning, M.D., M.S., W. Hartford, Conn.

Carl F. Jordan, M.D., C.P.H., Des Moines, Ia.

Karl F. Meyer, Ph.D., San Francisco, Calif.

Howard C. Stewart, M.D., Dr.P.H., Franklin, Tenn.

Ralph E. Wheeler, M.D., Dr.P.H., New York, N. Y.

Dorothy G. Wiehl, M.A., New York, N. Y.

Harry S. Mustard, M.D., Baltimore, Md.

UNAFFILIATED

Michael J. Bent, M.D., Nashville, Tenn.

Carolyn S. Whiting, R.N., Phoenix, Ariz.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Emil G. Ericksen, M.D., 122½ N. Phillips Ave., Sioux Falls, S. D., Health Officer
Harry B. Franchere, M.D., Altamont, N. Y., Health Officer
Matthew H. Griswold, M.D., 75 New Britain Rd., Kensington, Conn., Health Officer of Berlin
John D. Hunter, M.D., Box 173, Crowley, La., Director, Acadia Parish Health Unit
H. J. Mann, M.D., Brockport, N. Y., Health Officer and Medical School Inspector
Edward A. McLaughlin, M.D., State Office Bldg., Providence, R. I., Director, State Department of Public Health
John C. Sleet, M.D., Health Department, Norfolk, Va., Acting Health Commissioner
Rolla B. Stafford, M.D., State Dept. of Health, Topeka, Kans., Director of Rural Health
Paul von Haeseler, M.D., Romulus, N. Y., Health Officer

Laboratory Section

Katharine E. Cox, 1812 McClung St., Charleston, W. Va., Director, State Hygienic Laboratory
Lloyd D. Felton, M.D., Harvard Medical School, Boston, Mass., Assistant Professor of Preventive Medicine and Hygiene
Gesina A. F. de Holl, M.A., 1701-16 Ave., Birmingham, Ala., Bacteriologist, Bureau of

Laboratories, Jefferson County Health Dept.

Allen A. C. Nickel, M.D., Bluffton, Ind.

Wilfred J. Noonan, M.D., 14600 E. Jefferson Ave., Detroit, Mich., Research Clinic—Detroit Board of Health; Medical Director, Sherman Laboratories

Emil Weiss, M.D., 1853 W. Polk St., Chicago, Ill., Instructor of Bacteriology and Public Health, University of Illinois, College of Medicine

Vital Statistics Section

Catherine Alexander, 951 S. E. 55 Ave., Portland, Ore., Chief Clerk, Bureau of Health

T. Frederick Brunton, 197 Clarendon St., Boston, Mass., Assistant Actuary, John Hancock Mutual Life Ins. Co.

Mary E. Dalton, B.A., State Dept. of Health, Albany, N. Y., Assistant Statistician, Division of Vital Statistics

Helen D. George, A.B., 721 Gorsuch Ave., Baltimore, Md., Assistant Statistician, Bureau of Vital Statistics, State Dept. of Health

Mary Gover, D.Sc., 311 E. 30 St., Baltimore, Md., Associate Statistician, U. S. Public Health Service

Theodore A. Hill, 1707 Fairmont Ave., La Canada, Calif., Registrar of Vital Statistics, Los Angeles County Dept. of Health

Liverus H. Howe, 197 Clarendon St., Boston, Mass., Second Vice-President and Actuary, John Hancock Mutual Life Ins. Co.

Albert G. Love, M.D., Dr.P.H., Custom House, Philadelphia, Pa., Officer, Medical Corps, U. S. Army

George F. Lull, M.D., Dr.P.H., U. S. Army, Washington, D. C., Charge of Vital Statistics, Sub-Division Office of Surgeon General

Helen H. Marshall, R.N., 219 Boehne Bldg., Evansville, Ind., Executive Secretary, Vanderburgh County Tuberculosis Assn.

Vasilios G. Valaoras, M.D., C.P.H., Johns Hopkins School of Hygiene, Baltimore, Md., Student, Bio-statistics Dept.

August J. Vatter, 197 Clarendon St., Boston, Mass., Assistant Actuary, John Hancock Mutual Life Ins. Co.

Public Health Engineering Section

John J. Calman, 176 W. Adams St., Chicago, Ill., President, National Assn. of Master Plumbers

Harry H. Hendon, 216 Court House, Birmingham, Ala., Sanitary Engineer, Jefferson County

Mark D. Hollis, C.E., State Health Dept., Bismarck, N. D., Director, Division of Sanitary Engineering

Thomas D. O'Connell, 154 Norman Ave., Brooklyn, N. Y., Sanitary Inspector, New York City Dept. of Health

Food and Nutrition Section

Abraham Lichterman, Phar.D., 17 Old Orchard Rd., New Rochelle, N. Y., Inspector of Foods and Drugs

Leland S. McClung, Ph.D., American Can Co., Maywood, Ill., Research Bacteriologist

Child Hygiene Section

Thomas H. Blake, State Health Dept., Charleston, W. Va., Director, Division of Child Hygiene

Elizabeth J. Sachs, 125 De Sota St., Pittsburgh, Pa., Supervisor, Communicable Disease Dept., Children's Hospital

Public Health Education Section

Charles C. P. Anning, D.P.H., P. O. Box 89, Public Health Dept., Pietermaritzburg, S. Africa, Medical Officer of Health

Fred D. Brown, M.D., 740 N. 5th St., Richmond, Va.

Emma V. Carlsson, Ph.D., Women's College of the University of North Carolina, Greensboro, N. C., Head of Hygiene Dept.

Angus Graham, M.D., London Life Ins. Co., London, Ont., Canada, Medical Director

Fleta H. Williams, M.D., 2730 Giddings St., Chicago, Ill., School Physician, Oak Park

Public Health Nursing Section

Mary P. Billmeyer, R.N., State Board of Health, Portland, Ore., Director, Division of Public Health Nursing and Child Hygiene

Dorothy L. Campbell, R.N., Plainwell, Mich., Family Health Counselor, Allegan County Health Unit

Rhoda P. Sheldon, R.N., 268 Guy Park Ave., Amsterdam, N. Y., Rural Public Health Nurse, Fulton-Montgomery Health Unit, State Dept. of Health

Unaffiliated

Guy G. Campbell, M.D., East Gary, Ind., School Physician

Percy E. Mauzey, LL.B., 2208 W. Washington St., Phoenix, Ariz., Acting Health Officer and City Dairy Inspector

WE APOLOGIZE

We apologize for the item carried in the August News from the Field erroneously listing the death of Dr. Ralph Hendricks, Health Officer of Spokane, Wash., who, we are happy to state, is much alive.

COMMITTEE ON RESEARCH AND STANDARDS MEETING

THE Executive Committee of the Committee on Research and Standards met in the New York office on July 19. The group reviewed the activities of the committee this year.

It was reported that the Laboratory Section Committee on Standard Methods for the Examination of Dairy and Food Products is engaged in preparing a new report on Shellfish Examination. The Committee on the Control of Communicable Diseases has completed the text for a new edition, which will be issued shortly. Revisions are planned for Milk Analysis and Water Analysis.

A new Sub-committee has been established on Standard Methods for the Examination of Dishwashing Devices. This group is planning to present a preliminary report of its findings at the Milwaukee Annual Meeting.

During the year the committee has studied the many standards promulgated by the Association in past years in an attempt to determine the need for new procedures. Preparation for revision of many of the old methods has been made during the past year, with the result that many adjustments are now in sight.

Through its various sub-committees and Section committees allocated to it, the Committee on Research and Standards has coöperated with other

agencies on research problems. It has assisted in the study and preparation of numerous reports. It has just appointed three members to serve on a joint committee with the American Society of Civil Engineers and the American Water Works Association to adopt standard definitions used in water works practice.

The committee will continue to act as a coördinating and stimulating agency. It believes that in this fashion it can best serve the members of the Association. It will welcome suggestions from the membership as to ways in which it can be of greater assistance to them in their problems.

The Committee on Research and Standards has been devoting all of its energies to the development of the underlying bases, both in method and in standards of quality, for administrative action in the public health field. Its concern is primarily with providing standardized tools to assist in administrative execution. The task is naturally not a spectacular one, but it does result in the provision of carefully developed yardsticks and technics of measurement, without which public health administration would not be able to function successfully.

A meeting of the Committee on Research and Standards will be held in Milwaukee during the Annual Meeting.

NEWS FROM THE FIELD

CONFERENCE OF STATE SUPERVISING NURSES

AROUND-TABLE conference of State Supervising Nurses will be held at the Hotel Schroeder in Milwaukee, Wis., Saturday, October 5, 1935. Among the topics selected by the State Supervising Nurses for discussion are:

Public Health Nursing as a Part of the Social Security Program

Minimum Qualifications for Public Health Nurses

Rural Field Experience Centers

Regional Staff Conferences

Lay Participation in the Health Program

Working Relationships with other Official and Non-official Agencies

Since much of the discussion will center around qualifications for public health nurses and public health nurse training facilities, the State Supervisors voted to invite the directors of the accredited public health nursing courses to attend the conference also.

Twenty of the 32 states which have supervising nurses will be represented at this conference and the majority of the directors of public health nursing courses will attend. All of the delegates plan to remain in Milwaukee for the Annual Meeting of the American Public Health Association the following week.

DR. HASSELTINE STRICKEN WITH PSITTACOSIS

H. E. HASSELTINE, M.D., F. A.P.H.A., Senior Surgeon of the U. S. Public Health Service, at the Marine Hospital in San Francisco, Calif., is seriously ill with pneumonia, contracted from psittacosis while experimenting with sera for its treatment.

This is the second time that he has been stricken with psittacosis, the first attack occurring in 1931 while he was making laboratory studies in San Francisco of the outbreak of the disease. . . .

Health Service officials said that, to the best of their knowledge, this was the first instance of a recurrence of the disease. . . .

Dr. Hasseltine, 26 years in the Public Health Service, has made studies of bubonic plague, parrot fever, and for 4 years worked in a leper colony at Hawaii.—*New York Times*, Aug. 3, 1935.

NEW BACTERIOLOGICAL SOCIETY FORMED IN ILLINOIS

THE Society of Illinois Bacteriologists was recently organized as a local branch of the Society of American Bacteriologists, at a meeting held in Chicago on May 8, 1935, at which the following officers were elected.

President: F. W. Tanner, Ph.D., Professor of Bacteriology, University of Illinois, Urbana, Ill.

Vice-President: Fred O. Tonney, M.D., Director of Research, Board of Health, Chicago, Ill.

Secretary-Treasurer: H. J. Shaughnessy, Ph.D., Chief, Division of Laboratories, State Department of Health, Springfield, Ill.

A governing council has been appointed by the president, to be presided over by the vice-president, which consists of representatives of the various interested groups; *i.e.*, the universities and colleges, the state and city health departments, the hospital laboratories, the commercial clinical laboratory, the packing industry, the

canners' industry, the milk industry, and any other groups which may be designated from time to time.

Active members must meet certain educational requirements and be actually engaged in the teaching or practical applications of bacteriology.

Associate members are those interested in bacteriology, but not necessarily professionally engaged in its study or application.

Two meetings a year are to be held.

The program committee, headed by Fred O. Tonney, M.D., has announced the following program for the first session on November 1, 1935.

Aims and Purposes, F. W. Tanner, Ph.D., *President*, Professor of Bacteriology, University of Illinois, Urbana, Ill.

Trends of Medical Bacteriology, A. A. Day, M.D., Professor of Bacteriology, Northwestern University, School of Medicine, Chicago, Ill.

High Points of Agricultural Bacteriology, Speaker to be selected.

What Bacteriology Means to Industry, W. Lee Lewis, Ph.D., Director, Institute of American Meat Packers, Chicago, Ill.

The outstanding character of the program for the first meeting augurs success for the new society.

ROTUNDA HOSPITAL INVITATION

ANDREW H. DAVIDSON, M.D., Master of the Rotunda Hospital, of Dublin, extends the facilities offered by the Rotunda Hospital for Post-graduate work to those members of the Association going abroad to study. The schedule giving the program of work at the Rotunda Hospital is available upon application to Dr. Davidson.

INTERNATIONAL UNION AGAINST TUBERCULOSIS

THE Executive Committee and the Council of the International Union Against Tuberculosis met in Paris, at the headquarters of the Union, July 10 and 11, under the chairmanship of Dr. Piestrzynski, Under Secretary of State

for Poland. Delegates from 20 countries attended. The administrative meeting of the Council was devoted to the preparation of the program of the Conference of Lisbon, scheduled for September 8-10, 1936.

NEW ENGLAND AND NEW YORK SEWAGE WORKS ASSOCIATIONS

A JOINT meeting of the New England and New York State Sewage Works Associations will be held at the Hotel Van Curler, Schenectady, N. Y., on October 4-5.

For the technical sessions an interesting and varied series of papers has been arranged. Displays of sewage works equipment will be presented by a large number of manufacturers.

Following the famous sunrise breakfast of the New York State Sewage Works Association with round table discussion, on October 5, this time for both associations, there is scheduled an inspection of the Schenectady and Canojoharie treatment plants. Another feature of the meeting is a tour of the General Electric House of Magic, for members and their guests, on October 4.

ELI LILLY AWARD

AT the summer meeting of the American Association for the Advancement of Science in Minneapolis, the Theobald Smith Award in Medical Sciences was established by Ely Lilly & Co., of Indianapolis. The new award will be \$1,000 and a bronze medal, which will be given yearly for "demonstrated research in the field of the medical sciences, taking into consideration independence of thought and originality."

Fellows of the American Association for the Advancement of Science are to submit to the permanent secretary's office in Washington, D. C., the name of a proposed recipient, with full information concerning his personality, training, and research work.

Any investigator who is less than 35 years old on January 1 of the year in which the award is to be made is eligible. Nominations must be received before May 1 each year.

The president of the association and 4 fellows will be the committee of award. The name of the winner will be announced at the summer meeting, and the presentation will be made at the winter meeting of the association.—*J.A.M.A.*, Aug. 10, 1935, p. 444.

COMMUNITY HEALTH CAMPAIGN

ANATION-WIDE publicity program is being planned by member agencies of the National Health Council, to bring about health consciousness in local communities, according to a letter sent by Dr. Louis I. Dublin, chairman of the publicity committee of the Council, to the state health officers in each of the states of the Union.

It is planned, reads the letter, that the climax of this publicity campaign will be a Colonial town meeting, held in each of about 400 cities in October or November. The slogan of the campaign is Health Today and Tomorrow. The coöperation of state and local health authorities and voluntary agencies will be a prime factor in achieving this end. This is strictly an educational campaign, not a drive for funds.

The active assistance of health officers and that of medical societies in these cities is urged, to organize in each community a local group which will conduct an inquiry into health conditions there, leading to thorough consideration of local health needs. The town meeting is to give opportunity for free discussion of problems brought to light by the local inquiries.

Most of the state health officers have promised to coöperate fully in carrying out this health-educational program of the National Health Council.

The member agencies of the National Health Council are American Heart Association, American Public Health Association, American Social Hygiene Association, American Society for the Hard of Hearing, American Society for the Control of Cancer, Conference of State and Provincial Health Authorities of North America, National Committee of Health Council Executives, National Committee for Mental Hygiene, National Organization for Public Health Nursing, National Society for the Prevention of Blindness, National Tuberculosis Association—all active members. Advisory members are American Red Cross, United States Children's Bureau, United States Public Health Service; associate members are American Nurses' Association and Foundation for Positive Health.

A manual with detailed suggestions for carrying on the health campaign, including the inquiry and holding a town meeting, is ready for distribution, and may be obtained by sending ten cents to the National Health Council, 50 West Fiftieth Street, New York City.

ILLINOIS FAIR HEALTH EXAMINATIONS

UNDER a coöperative plan of the Sangamon County medical and dental societies, local hospitals and the Illinois State Department of Health, it is planned that 1,000 children from 6 months to 2 years of age were to have complete physical examinations and mental tests at the Illinois State Fair in Springfield, Aug. 17-24.

Arrangements were made also to give chest examinations, including electrocardiograms, to from 2,000 to 3,000 adults.

NEW YORK PLANS HEALTH CENTERS

ANEW district health center to be built under a program planned by the Department of Health was begun with the laying of the cornerstone re-

cently, in the Mott Haven district of the Bronx, New York, N. Y.

The Public Works Administration provided funds for 7 of these centers, of which the Mott Haven unit will be the first.

STUDY OF MATERNAL CARE

THE Children's Bureau is now engaged in the preparation of a report on community provisions for maternal care in Hartford, Conn., where the first of what is expected to be a series of studies of this subject was recently completed. The purpose of this series of studies is to ascertain: (1) The type of maternal care received by an unselected series of mothers in different localities; and (2) the proportion of these mothers and infants having abnormal conditions or diseases.

The study was undertaken in Hartford at the invitation of the Hartford Medical Society, the Hartford Health Department, and the 4 Hartford hospitals. An advisory committee of 5 members, representing also the local hospitals, was appointed by the Medical Society.

All deliveries at 28 weeks or more gestation, occurring in Hartford to Hartford residents between May 1, 1933, and May 1, 1934, were studied, about 2,250 cases in all.

The deliveries occurring during 6 months, April, May, June, 1933, and January, February, March, 1934, were studied in detail. A special grouping of months was selected to determine whether the fact of making the study was in itself influencing the care given. Physicians who had attended the private patients were interviewed and prenatal and postnatal data secured, and permission to abstract the hospital chart obtained. Post-delivery visits were made to homes to interview mothers. At these interviews a history of the health of mother and child was

taken, but no examinations were made.

The records of the Visiting Nurses Association pertaining to these cases were also studied, and items of interest from past histories were checked to hospital and clinic records where possible.

For about half of the deliveries, the delivery and immediate postpartum period was studied by means of data obtained from hospital and clinic records in the cases of hospital deliveries, and in cases of home deliveries by means of interview with the physician or midwife. A. W. H.

MUSHROOM POISONING

. . . The most deadly species of mushroom, *Amanita phalloides*, which causes more than 90 per cent of the deaths from mushroom poisoning, thrives from early June until the first autumn frosts. The flavor of this mushroom is reported to be delicious; the young specimens are the most poisonous and are also most apt to be mistaken for the edible forms by the inexperienced mycologist. Other persons, even less prudent, may ingest toxic varieties after trying various "tests" on them. One of the common kitchen examinations consists in placing a piece of bright silver in the utensil while the plants are cooking. If the silver is not tarnished, the mushrooms are considered safe for consumption. The efficacy of this worthless test is believed in by an astounding number of people.

Some of the fatalities observed in this country due to mushroom poisoning are caused by another variety of mushroom, *Amanita muscaria*. This species also is common in all parts of the United States. The action of the toxins from this type of mushroom is, apparently, more rapid than is that of the poisons present in the various forms of *Amanita phalloides*. Thus there are in general two types of mushroom

poisoning that may be encountered: the so-called rapid type (*mycetismus nervosus*), due to *Amanita muscaria*, and the delayed type (*mycetismus choleraiformis*), caused by the various forms of *Amanita phalloides*.—Editorial, *J.A.M.A.*, July 6, 1935, p. 34.

CHOLERA BACTERIOPHAGE IN INDIA

THE following statements regarding the experience with the use of cholera bacteriophage in India are taken from the *Annual Report of the Director of the Eastern Bureau of the Health Organization of the League of Nations at Singapore, for 1934*:

Madras—The conclusions reached were that—

1. The prophylactic administration of bacteriophage did not reduce the attack rate.

2. The prophylactic administration did appear to lessen the mortality rate.

3. Bacteriophage was not more useful than prodiarrhea mixture in the treatment of cholera.

Assam—They conclude that "the results establish a sufficient probability in favor of a significant effect of the administration of bacteriophage to form a basis of practical policy in the treatment and prevention of cholera in villages."

Cachar—"As far as figures from reliable data can show, there is no doubt that bacteriophage is an efficacious treatment for cholera."

In Nowgong and Habiganj, cholera-dysentery bacteriophage for the treatment of all diarrheas, dysentery, and suspected cholera has been continued. In Nowgong there has been no epidemic outbreak for 4½ years, and in Habiganj for 3 successive cholera seasons.—*Pub. Health Rep.*, July 12, 1935, p. 912.

20,000 NEW YORK CHILDREN IMMUNIZED

TEN weeks campaign for immunization of children against diphtheria, conducted by the Department of Health in Brooklyn and Manhattan, resulted in the protection of

14,591 in Brooklyn and 7,346 in Manhattan.

The New York City board of education, medical societies, Catholic school boards, and social and civic organizations of the 2 boroughs coöperated, and school children acted as special health officers to round up children under 6 years of age and have their parents sign immunization requests.

MICHIGAN HAS NEW HEALTH UNIT

THE establishment of a new health unit in Calhoun County, Mich., with Dr. Matthew R. Kinde, of Hastings, as Director, has been announced. The unit, which is a project of the W. K. Kellogg Foundation, is financed in part by appropriations of \$6,000 and \$3,000, respectively, by the county and state. It will open officially September 1.

Dr. Kinde, member A.P.H.A., has resigned as Health Director of Barry County to take over the new office. He has been succeeded by Robert B. Harkness, M.D., member A.P.H.A., Acting Health Officer of Eaton County for the past 3 months.—*J.A.M.A.*, July 20, 1935, p. 206.

FILM ON PUBLIC HEALTH SUBJECT

THE first motion picture, with sound and music, ever made on a public health subject is the new film called "Contacts," produced by the Hennepin County Tuberculosis Association of Minneapolis, in coöperation with the University of Minnesota.

This film shows what happens in a typical American home when there is an unsuspected case of tuberculosis within the family circle. It emphasizes the fact that tuberculosis is not inherited, that it may hide behind a mask of good health, that early cases of tuberculosis can only be located through the use of the tuberculin test and the X-ray, that every case comes

from another, and that the disease is spread among "contacts." The modern weapons in tuberculosis control, such as the use of the tuberculin skin test and the X-ray, public health education, and sanatorium treatment are reviewed in what is stated to be a highly effective panorama at the close of the picture.

"Contacts," now available to other groups and organizations, is being distributed through the National Tuberculosis Association and the Hennepin County Tuberculosis Association. It is a two-reel film made up in both 16 mm. and 35 mm.

KANSAS RESEARCH DEPARTMENT ESTABLISHED

THE establishment of a department of medical research at Bell Memorial Hospital, Kansas City, Mo., as a part of the work of the University of Kansas School of Medicine, with Dr. Ralph H. Major, Professor of Medicine, as director, has been announced. Clarence J. Weber, Ph.D., Instructor in Medicine, has been named associate in medical research.

INTERNATIONAL MEDICAL WEEK

UNDER the patronage of the Federal Council of Switzerland, an International Medical Week will be held at Montreux, September 9-14. Dr. Henry E. Sigerist, of Baltimore, is included among the speakers listed on the program; his subject will be "The Present Unrest in the Medical World."

In addition to lectures there will be clinics presented by the faculty of the University of Lausanne.

PASTEUR MEDAL AWARDED DR. KUHN

PROF. RICHARD KUHN, Director of the Institute for Chemistry in Kaiser-Wilhelm Institute for Medical Research, Heidelberg, Germany, has been awarded the Pasteur Medal by the Société de chimie biologique.

PERSONALS

DR. ARTHUR E. LIEN, of Spokane, has been appointed County Health Officer of Spokane County, Wash.

JOHN L. JONES, M.D., member A.P.H.A., until recently Assistant State Health Commissioner and Epidemiologist of Tennessee, has been appointed State Health Commissioner of Utah, to succeed Dr. T. B. Beatty, F.A.P.H.A., who has retired after many years of service. Dr. Jones is a graduate of the Harvard School of Public Health and for several years was epidemiologist in the Kentucky State Department of Health.

SOL PINCUS, F.A.P.H.A., has been appointed an additional Deputy Commissioner in the Department of Health of the City of New York. He is to head up the work carried on by the Sanitary Bureau and the Bureau of Food and Drugs. This position was created by the budget last year. From 1916 to 1923 Mr. Pincus was attached to the U. S. Public Health Service, as sanitary bacteriologist, then as sanitary engineer in various capacities, including state and district health work in the fields of water supply, milk supply, and the control of communicable diseases. In 1929-1931 Mr. Pincus was in charge of the administrative work and public health studies of the Philadelphia Hospital and Health Survey directed by Dr. Haven Emerson. He has recently been engaged in the construction and operation of public swimming pools.

THOMAS PARRAN, JR., M.D., New York State Health Commissioner, F.A.P.H.A., sailed recently for Europe, for the purpose of studying the social diseases situation in the Scandinavian countries.

KATHARINE TUCKER, R.N., F.A.P.H.A., General Director and Secretary of

the National Organization for Public Health Nursing, has accepted the position of Director of the newly organized Department of Nursing Education of the University of Pennsylvania, Philadelphia, Pa., effective September 1, 1935. The Board of Directors of the N.O.P.H.N. has appointed Alma C. Haupt, R.N., F.A.P.H.A., Acting Director, until the Board meeting in October, at which time it is hoped that a permanent successor to Miss Tucker will be named.

FRANCIS GEORGE CURTIS, M.D., F. A.P.H.A., Chairman of the Newton (Mass.) Board of Health for 42 years and one of the best known public health authorities in New England, has retired from active service. In addition to being chairman of the body, Dr. Curtis has served for many years as health officer of the City of Newton. He was first appointed to the Board of Health in 1893, and has been continuously reappointed by succeeding mayors. During the more than four decades that Dr. Curtis has supervised public health activities in Newton, he has brought his department to a high state of efficiency. For more than half of his term of service the office carried no remuneration. Previous to his connection with the Health Department, Dr. Curtis was for a number of years superintendent of the Newton Hospital, also an unpaid post. Dr. Curtis has been an active member of state, national, and international health organizations and has attended most of their conventions. He has been a member of the A.P.H.A. since 1897, and is a Charter Fellow.

BRIG. GEN. MATTHEW A. DELANEY, Commandant of Medical Field Service School, U. S. Army, Carlisle Barracks, Pa., received the honorary degree of Doctor of Science at the

annual commencement of Dickinson College, Carlisle, Pa., on June 10. He is a member of the A.P.H.A.

DR. EDWARD J. FINN has been appointed to succeed Dr. Francis I. Nettleton as Health Officer of Shelton, Conn.

DR. JOHN D. MILBURN has been appointed to succeed the late Dr. Frederick T. Fitch, member A.P.H.A., as Health Officer of East Hampton, Conn.

DR. ALBERT B. MCCREARY, of the Health Department of Memphis, Tenn., has been appointed to take charge of a district health unit in Virginia, with headquarters at Eastville, Va.

DR. DONALD C. BALFOUR, Professor of Surgery, University of Minnesota Graduate School of Medicine, Rochester, Minn., has been appointed Associate Director of the Mayo Foundation, a newly created position.

LESLIE A. LAMBERT, M.D., member A.P.H.A., of Flint, Mich., has been named Health Officer of Flint, to succeed Dr. Kenneth B. Moore, who resigned to study at the University of Michigan.

CLYDE C. SLEMONS, M.D., F.A.P.H.A., of Lansing, Mich., has been reappointed Health Commissioner of Michigan.

ARTHUR E. MCCLUE, M.D., member A.P.H.A., of Charleston, W. Va., has been reappointed State Health Commissioner for a term of 4 years.

DR. THOMAS H. BLAKE, of Buffalo, has been appointed Director of the Division of Child Hygiene of the West Virginia State Department of Health.

ELROY F. MCINTYRE, M.D., member A.P.H.A., of Sante Fe, N. M., was elected President of the New Mexico Public Health Association recently.

DR. SANFORD VINCENT LARKEY, since 1930 librarian and assistant professor

- of medical history and bibliography at the University of California School of Medicine, San Francisco, has been appointed Librarian of the Welch Medical Library of Johns Hopkins University, succeeding the late Dr. Fielding H. Garrison.
- WILLIAM H. EATON, M.D., F.A.P.H.A., for many years Health Officer of Santa Barbara, Calif., has been succeeded by Dr. Clarence T. Roome.
- DR. EUGENE H. DICKENSHIED, of Allentown, Pa., has been appointed Medical Director of Lehigh County, to succeed J. Treichler Butz, M.D.
- LYMAN W. CHILDS, M.D., member A.P.H.A., has announced his retirement as Supervisor of Health Service in the Cleveland Schools. He was appointed to the Cleveland, O., school staff in 1910.
- DR. ESMOND R. LONG, Director of the Laboratory of the Henry Phipps Institute of the University of Pennsylvania, Philadelphia, Pa., member A.P.H.A., has been made Director of Phipps Institute. Dr. Charles J. Hatfield, former Director, will be Associate Director, and Chairman of the Board of Directors in charge of the Institute. Dr. Henry R. M. Landis will have the title of Associate Director in charge of the Clinical and Sociological Departments.
- EDWARD R. DAVIES, M.D., member A.P.H.A., of Kingwood, W. Va., has resigned as Health Officer of Preston County, to take a similar position in Baltimore. Dr. Charles Y. Moser, of Terra Alta, succeeds Dr. Davies.
- AMY LOUISE HUNTER, M.D., member A.P.H.A., of New Haven, Conn., has been appointed Supervisor of the Wisconsin State Bureau of Maternity and Child Welfare, to succeed Charlotte J. Calvert, M.D., member A.P.H.A., retired.
- DR. JOSEPHUS J. P. BOWDOIN, of Atlanta, Ga., has been given a life membership in the Seventh District of the Georgia Congress of Parents and Teachers "in appreciation of his service to the children of the state."
- THOMAS C. GRUBB, Ph.D., has been appointed a member of the Illinois State Department of Health, and will conduct research in the control and prevention of disease.
- OLLIE M. GOODLOE, M.D., member A.P.H.A., of Paducah, Ky., has been appointed Health Officer of Mason County, with headquarters at Maysville, Ky.
- DR. AUBREY Y. COVINGTON has been appointed Health Officer of Union County, with offices at Morganfield, Ky.
- DR. JOHN H. WEAVER has been appointed Health Officer of Hope, Ark.
- DR. ANDREW S. GREGG has been appointed Health Officer of Fayetteville, Ark.
- DR. BENJAMIN J. TEAFORD, of Jonesville, has been appointed Health Commissioner of Bartholomew County, Ind.
- DRS. WILLIAM ALLEN DECKERT, JOHN M. HAWS, and ISADORE A. SIEGEL have been appointed Health Officers in the division of maternity hygiene of the Baltimore Health Department, Baltimore, Md.
- DR. JAMES L. MCCARTNEY, Director of Mental Hygiene at the Battle Creek Sanitarium, Battle Creek, Mich., has resigned to become Chief Psychiatrist at the New York State Vocational Institution on the Hudson River at West Coxsackie, N. Y., a correctional institute operated by the New York State Department of Correction for boys between the ages of 10 and 16.
- DR. LINDA GAGE ROTH, Dean of Women at Battle Creek College, Battle Creek, Mich., was elected President of the Michigan Student Health Association recently.
- DR. SAYERS J. MILLER has been ap-

pointed Director of the Student Health Service at Purdue University, Lafayette, Ind.; he has been acting director since the death of Dr. Oliver P. Terry.

DR. FRANK W. PARKER, JR., of San Bernardino, Calif., has been appointed District Health Officer in charge of Grant, Luna, and Hidalgo Counties, with headquarters in Silver City, N. M.

DR. FRANK J. CONAHAN, of Bethlehem, Pa., has been appointed Medical Director of Northampton County, to succeed the late Dr. Edgar M. Green.

DR. KENNETH M. LYNCH, of Charleston, S. C., has been appointed to the South Carolina State Board of Health, to succeed Dr. Robert Wilson, resigned; and Dr. Walter R. Mead, of Florence, succeeds the late Dr. William Egleston, of Hartsville, S. C.

DR. FRANCIS P. WISNER, of Marysville, Calif., has been appointed Health Officer of Sutter County, to succeed Dr. Trusten P. Peery.

DR. EDWARD J. ENGBERG, of St. Paul, Minn., for many years Secretary of the Board of Medical Examiners, was appointed a member of the Minnesota State Board of Health, to succeed the late Dr. Helen H. Hielscher. Dr. Max W. Alberts, of St. Paul, succeeds Dr. Engberg on the Medical Board.

DR. JONES L. HURST, of Dorset, O., has been appointed Health Commissioner of Ashtabula County, O., to succeed the late Dr. Walter S. Weiss, of Jefferson.

DR. J. GLENN HEMINGTON, of Uniontown, Pa., has been appointed Health Director of Fayette County, Pa.

DR. JOHN W. L. COOPER has been appointed Health Officer of Chattanooga, to succeed Dr. Frederick C. McIsaac.

DR. SAMUEL P. HALL, JR., formerly of

Chickamauga, Ga., has been named Health Commissioner of Walker County, Ga., to succeed Dr. Rufus F. Payne, who resigned to accept a position with the CCC Camp at Fort Oglethorpe.

DR. HOWARD H. VOLAN, of Syracuse, N. Y., has been appointed Epidemiologist in the Syracuse Department of Health, to succeed Dr. Gregory D. Mahar, who was recently made Health Commissioner.

DR. WILLIAM A. CARRIGAN, of Society Hill, has been appointed Health Officer of Darlington County, S. C.

DR. SEDGWICK SIMONS, of Georgetown, has been appointed Health Officer of Beaufort County, S. C.

HUBERT S. JACKSON, D.D.S., of San Antonio, and Dr. William P. Harrison, of Teague, have been appointed to the Texas State Board of Health.

DR. THOMAS N. GOODSON, of San Antonio, has been appointed Health Officer of Bexar County, Tex., and Dr. Lawton C. Biggers, of Bonham, of Fannin County.

DR. HINTON D. JONEZ, of Tacoma, was recently appointed Health Officer of Pierce County, Wash., to succeed Dr. James H. Egan.

DR. ARTHUR M. SONNELAND, of Bellingham, has been appointed Health Officer of Whatcom County, Wash., succeeding Dr. Johan C. Wiik.

DEATHS

DR. RUFUS CHOATE, Washington, D. C., who began the practice of medicine as an army surgeon during the Indian campaigns and continued it for almost half a century, died July 26, at the age of 88.

DR. JAMES ARMITAGE EMERY, Acting Chief of the Biochemic Division, Bureau of Animal Industry, U. S. Department of Agriculture, Washington, D. C., died July 28, at the age of 68.

PROFESSOR JOHN WEINZIRL, of Seattle, Wash., died the latter part of June.

He was a Fellow of the A.P.H.A.

FREDERICK T. FITCH, M.D., formerly Health Officer of East Hampton, Conn., member A.P.H.A., died recently.

CHARLES A. BEVAN, M.D., formerly Health Officer of West Haven, Conn., died recently. He was a life member of the A.P.H.A.

CONFERENCES

Sept. 12-14, Mississippi Valley Conference on Tuberculosis, Madison, Wis.

Sept. 20-Oct. 2, 7th International Medical Post-Graduate Congress, to be held during the World Exhibition, under the auspices of the University of Brussels, Bruxelles-Spa, Belgium.

Sept. 30-Oct. 4, American Hospital Association, St. Louis, Mo.

Sept. 30-Oct. 4, 21st National Recreation Congress, sponsored by the National Recreation Association, Chicago, Ill.

Oct. 3-5, Association of Military Surgeons of the United States, New York, N. Y.

Oct. 4, 5, Joint Meeting of the New England and New York State Sewage Works Associations, Schenectady, N. Y.

Oct. 5, Round Table Conference of State Supervising Nurses, Milwaukee, Wis.

Oct. 5-7, Conference of State Sanitary Engineers, Milwaukee, Wis.

Oct. 7-10, Sixty-fourth Annual Meeting of the American Public Health Association, Milwaukee, Wis. Headquarters: Hotel Schroeder.

Oct. 7-10, Annual Meeting of the American Association of School Physicians, Milwaukee, Wis.

Oct. 7-10, Meeting of the American

Association of State Registration Executives, Milwaukee, Wis.

Oct. 7-10, Meeting of the International Society of Medical Health Officers, Milwaukee, Wis.

Oct. 7-10, State Laboratory Directors Conference, Milwaukee, Wis.

Oct. 7-10, Conference of Wisconsin Health Officers, Milwaukee, Wis.

Oct. 8-11, Meeting of the Association of Dairy, Food and Drug Officials, Milwaukee, Wis.

Oct. 10-11, Meeting of the International Association of Dairy and Milk Inspectors, Milwaukee, Wis.

Oct. 14-18, 24th Annual Safety Congress, National Safety Council, Inc., Louisville, Ky.

Oct. 28-31, 18th Annual Meeting, American Dietetic Association, Cleveland, O.

Nov. 1, First Session of the Society of Illinois Bacteriologists, Chicago, Ill.

Nov. 1, 2, School Health Conference, sponsored by the Department of School Health and Physical Education of the National Education Association, Philadelphia, Pa.

Nov. 15, 16, Sixty-first Annual Meeting, New Jersey Health and Sanitary Association, Hotel Berkeley-Carteret, Asbury Park, N. J.

Nov. 19, 20, Annual Meeting of the Southern Branch, American Public Health Association, St. Louis, Mo.

Dec. 30-Jan. 4, 1936, Winter Meeting of the American Association for the Advancement of Science and Associated Societies, St. Louis, Mo.

Apr. 22-25, 1936, National Tuberculosis Association, New Orleans, La.

May 11-15, 1936, American Medical Association Convention, Kansas City, Mo.

July 27-31, 1936, Second International Congress on Mental Hygiene, Paris.

Sept. 8-10, 1936, International Union Against Tuberculosis, Lisbon, Portugal.

Health Information on the Air*

ALAN BLANCHARD

Publicity Director, California Tuberculosis Association, San Francisco, Calif.

WITH millions of dollars invested; with millions pouring in, with world-wide broadcasts a frequent occurrence; with the growing threat of television; and with the complete capitulation of all the die-hards among advertisers, entertainers, and the public who held out against it; radio is having growing pains.

Ten thousand dollars an hour is what radio's sponsors pay out to entertain us during the 18 hours of the radio day. Sponsors last year paid over \$72,000,000 for broadcasting time.

Radio has expanded so explosively that its actions appear somewhat insane. No one knows just where it is going—how big it will grow. Young executives sit in handsome offices, and though somewhat bewildered by it all, they perhaps know best radio's possibilities.

There are many contradictions to be found on the cost sheets of radio. Actors are eager to work for \$10 or \$15 a performance. Script writers will do a 15 minute play (remember that a stage play runs about 1 hour and 15 minutes) or even a 30 minute play for

\$25; but Eddie Cantor, Al Jolson, and Ed Wynn reputedly cannot work for less than \$6,000 a performance.

One wide-spread program costs its sponsor but \$22.50 for talent—that is for the organist—but Amos and Andy each get about \$75,000 a year and, all in all, the sponsors spend about \$160,000 a year to tell us about these two negroes—and of course tooth paste and mouth wash.

Half hour program costs may run from 0 to over \$20,000, depending on the talent and the extent of the broadcasting chain.

Stations vary in impressiveness from enormous and magnificent New York studios of the large chains, to a back room off a small tradesman's shop. All of these stations have similar call letters, and on the air—what with the magic of high fidelity electrical transcriptions and modern receiving sets—it is sometimes difficult to distinguish between the big and the little stations by the quality of their programs. All these stations are trying to reach the public—you and me and the man on the street—and most of them are doing it very effectively. Newspapers claim that radio is taking away their circulation; and all of us know many people whose major contact with the world is

* Read at the Sixth Annual Meeting of the Western Branch, American Public Health Association in Helena, Mont., July 2, 1935, as part of the report of the Committee on Health Education Methods.

through the radio. It can be well imagined that there are a large number of people in this country whose only source of information, other than back fence gossip, is their radio receiving set.

It was this bewildering new medium for the spreading of information that your Committee on Health Education wished to examine with a view toward using it more effectively. Much has been said among educators in general about the need for governmental control of radio, in order that its social value might be enhanced by turning it over to educational work. Criticism has been directed against the monopolizing of radio by advertisers for big business. Health workers have claimed that the pseudo-health programs of advertisers fill the air and spread dangerous half-truths about hygiene and disease.

Every one of us, each with his own special message with which he would indoctrinate the masses, feels that at least a portion of the time on the air should be set aside for that purpose. We all forget that radio is in the unique position of being in the show business, while its revenues are derived from advertising. The public wants this new medium mainly for entertainment, and someone must pay the bill. The health worker may want to tell the world about the danger of communicable disease—in a dry-as-dust talk—but he, himself, listens only to "One Man's Family."

Your committee in approaching the problem of health education by radio wished to know the amount and nature of health information now being given on the air: the policies, and changing trends in policy, of the radio stations toward health broadcasts, both commercial and non-commercial or sustaining; in order that the committee might suggest a plan for health workers to follow for their greater and more effective use of radio.

Accordingly your committee conducted a survey of all radio stations in the San Francisco Bay Region, gathering information on the legislation related to radio and advertising, and other information touching on health broadcasting. The survey of the San Francisco Bay Region was chosen for its convenience, but it is believed that the findings apply with little variation to other regions in the West.

Two questionnaire forms were made up—the first listing all programs carried by a station, both commercial and non-commercial or sustaining, that touch in any way on health subjects. The second questionnaire listed questions on station policy in regard to health programs.

There are 12 commercial radio stations in the Bay Region. There are 2 National Broadcasting Company chain stations, 1 Columbia Broadcasting System chain station, 2 stations operating under the same management, one being in San Francisco, the other in San Jose, 2 newspaper stations, 1 being part of the Hearst chain, the other being run by the *Oakland Tribune*, 2 independent stations of important size, and 3 small independent stations.

The committee first tried to get from the National Association of Broadcasters in Washington, D. C., from the National Advisory Council on Radio in Education, and from other sources compilations showing the extent of health broadcasts in various regions of the country, but finding that such data have not been gathered, decided to get this information from the sample group of 12 stations mentioned.

The first questionnaire listed the following points related to the health broadcast programs:

1. The radio station
2. The name of the program
3. The name of the sponsor (or if the program is sustaining)
4. The days the program is broadcast

5. The time of day and the length of time the program is broadcast

6. The type of program (whether music and announcements, dramatic sketch and announcements, health talk, etc.)

7. The product or service advertised

8. The type of health information given

9. Comments on the quality of the health information given

This last point was the opinion of the committee and was filled out only for those programs with which the committee was familiar. The other information was supplied by the broadcasting station, and for each station covers the programs for 1 week.

The committee visited each station directly to obtain this information. With but one exception, the stations willingly supplied the information. In the case of the one station refusing (one of the independent stations of important size) an estimate of the programs was made from various newspaper listings, and the answers to the questionnaire on policy were deduced from the manager's statements.

One factor which, more than the station or the habit of the listeners, affects the distribution of the audience is the entertainment quality of the program. Advertising surveys have indicated that this factor is the most important of all; so in considering the programs that follow we can only hazard a guess—based on the hour of the day, the chain system, and other known factors—at the number of persons that the good and bad health programs are affecting.

The NBC stations are carrying 19 commercial programs that deal in some way with health subjects. Two of these are on the smaller station KGO, and the other 17 are carried on the larger station, KPO. All of these are entertainment programs—mostly variety shows, dramatic sketches, musical programs—though there is one cooking chat, and also one of comment on public affairs. None of these programs

may be classed as "Health Talks." The health qualities of the product or service advertised are told in the announcements, which are usually short. A sample is the Pepsodent program "Amos 'n' Andy."

A number of these programs are given but once a week; many are given in series of 3 to 5. The air time amounts to 10 hours and 45 minutes a week on KPO, and 2 hours a week on KGO. This is out of a total air time on each station of 126 hours a week.

The value of air time varies with the time of day. It is known that the audience is small in the morning, steps up to a higher level during the afternoon, and steps up rapidly again during the evening from 5:30 to 10:30 p.m. Sunday afternoon compares with the peak evening time during the week.

The committee made a detailed analysis of the time allotted by each station to the various classes of health program which has been omitted on account of space.

On all the 12 Bay Region stations, a total of 44 hours and 45 minutes of commercial programs that touch on health subjects are carried. Health education programs are carried only on the important stations, and total 1 hour and 58 minutes a week in time.

At present no dangerous commercial health programs are known, and the few poor ones on the important stations are expected to be removed shortly.

The amount of time given health education seems very small, but this time is on important stations and is at good periods in the day. Irregularly these stations give more time to this subject. It should be remembered that health is only one phase of the educational work these stations are doing.

In considering the question of station policy, it was decided that a questionnaire covering many definite points, such as "Does the station take laxative advertising?" would not prove

satisfactory, since one exception would make the answer give an untrue picture of the station's policy. Therefore, a set of very general questions was prepared, the answers to be filled in at an interview with the station manager. The questions are:

Has the station any policy on the amount of air time given:

1. To health subjects?
2. To general education?

If so, does the policy apply to commercial programs?

Has the station any policy on the nature of health subjects which may be discussed?

Has the station any policy on the high level of the products advertised on commercial health programs?

Is the opinion of medical or health authority sought?

Has the station any policy on the high level of information given on commercial health programs?

Has the station any sustaining health programs, or non-commercial health programs? What sort?

Would the station be willing to give time on the air to a representative public health group, such as city or county health department, or branch of the American Public Health Association?

Would a minimum fee be requested?

The information given allows us to group the stations in 4 classes. We believe similar classifications could be made in other regions. Our classes are:

The chain stations: NBC and CBS

The newspaper stations: KYA and KLX

The large independents: KJBS, KQW, KROW, KSFO

The small stations: KRE, KLS, KGGC

The chain stations have the most definite plan for educational broadcasting. Both chains contribute time and some funds to educational programs. NBC has an educational division in San Francisco, with a full-time director who is engaged in forwarding and coördinating this work. NBC, in its health education work, prefers to deal with various health groups through some official and unassailable

body, such as a university. It was pointed out that there is so much friction between different units in the health field—the physicians, health workers, chiropractors, religious cults, etc.—all of which the radio station must recognize and treat with equality, it is difficult for the station to work with any one group. However, were the Western Branch to represent a wide enough range of health activities, they would be more able to forward a program we might devise.

The newspaper stations are run with a policy similar to a newspaper, and would forward health programs having news interest. Their educational work, more sporadic than that of the chains, still is of definite value.

The independent stations have developed educational programs where there has been stimulation from educational groups. The scarcity of health education programs on these stations is a reflection on health workers.

The small stations are willing to coöperate with any community group, but prefer to hold to their general plan of records and spot announcements, rather than develop more elaborate programming.

In relation to commercial programs that touch on health, certain general checking on the product is done by all stations. The chains usually check with their national offices. The newspaper stations check with the advertising bureaus of the newspapers, and further check is made on the nature of the information to be given before the program is allowed on the station. The independents may be more or less careful, depending on the nature of the management. Where there has been coöperation with health and educational groups, there usually develops a higher consciousness of community obligation on the part of the management. The small stations get few advertising offers in this class, and usually

the small stations are connected with some church, or business organization—radio is a side line—and do little in the advertising field.

The general policy of all stations in relation to commercial health programs is founded on good taste, rather than on the careful picking of the product for its health values. CBS has recently issued an order that all programs for laxatives, deodorants, internal remedies, etc., carried on the chain be discontinued as soon as their contracts expire; and in the meantime is closely watching the advertising on such programs. NBC has long followed a similar policy, and most of the other stations are doing likewise. This policy was best expressed by the manager of one of the independent stations, who pointed out that the radio program goes into the "family circle," and is seldom heard by individuals alone. No objectionable subjects should be presented on the air. Although the stations are losing many immediately profitable contracts, they have found it better business to discontinue such programs.

Health workers may welcome this change that is bringing the removal from the air of all programs advertising internal remedies and like products, but they may not realize that this same trend means the removal of many of their own health programs on similar grounds. It is quite apparent—and many of the station managers pointed this out—that health programs dealing with pathologic conditions, discussing the details of disease, and of a morbid nature, are equally objectionable with such commercial health programs as mentioned. Your committee believes that certain channels should be used for disseminating various types of health information, and that radio is the channel for only a part of this information; and believes that health workers might best follow the example of advertisers when they prepare their

radio programs. Radio health programs should deal with beauty, happiness, and the positive values of health, rather than with disease and the morbid aspects.

Another factor, other than the improvement of taste, which is improving the quality of commercial health programs, is the extension of legislation against such programs. Your committee corresponded with the Federal Communications Commission (which was the Federal Radio Commission) in Washington, D. C., and visited the San Francisco branch offices of the Federal Communications Commission, the Federal Trade Commission, and the Food and Drugs Administration; and learned the nature of this present and proposed legislation.

It was found that health workers have the legal weapon to force off the air any "quack" health program that can be shown to be dangerous to the public health. The Federal Communications Act, designed primarily to exert control over the engineering factors in the field of communications, also gives the Commission power to rule off the air stations carrying programs that are objectionable from a general public interest or public service standpoint. The Commission has no power to censor such programs in advance, but on the receipt of a sufficient number of complaints, or the complaint of any responsible group or official, may investigate them; and if the complaints seem warranted, conduct a hearing. If, in the Commission's judgment, the program is against the public interest, it may revoke the license of the radio station carrying the program.

To date, 5 stations in the United States have had their licenses revoked by the Commission. Three of these were penalized because of "quack" medical programs. One was for the notorious Dr. J. R. Brinkley's Goat Gland Treatment program, carried on

a station in Kansas, and later moved across the Mexican border. The other 2 advertised cancer "cures"; Norman Baker's program being carried by an Iowa station, the other by a station in Oregon.

At present the licenses of 5 stations in Los Angeles are awaiting the judgment of the Commission on a hearing conducted in relation to programs advertising a "Neurometer," a mechanical instrument designed to diagnose human ills. Also 21 stations, many of them prominent, will have to prove to the Commission on October 3 "that their continued operation will be in the public interest." The action was taken because the stations had broadcast advertisements of a reducing preparation, which the Commission held was inimical to the public health.

Radio stations are active in bringing to the Commission's attention programs of this sort asking for the Commission's opinion on a proposed program, or complaining of programs carried by other stations. As has been said, the Commission has no power to censor programs in advance. Radio stations complain of this ruling, saying that no standard is set up whereby they may determine the acceptability of a program; they have to take their chances, and risk citations on the renewal of their licenses. However, the Commission's ruling is working to inhibit the stations from accepting commercial health programs of a dangerous nature.

It should be understood that the Commission has power only to rule against programs that are proved to be definitely dangerous to the public health. Before seeking action by the Commission, health workers should make sure that the program of which they complain falls within that definition. The Commission is located in Washington, D. C. Branch offices in the West are in San Francisco, Los

Angeles, Portland, Seattle, and Denver. Complaints against programs should be filed with the Commission through these offices. Electrical recordings and court reporter transcriptions of programs, properly certified, are used by the Commission when conducting hearings, and should be filed with complaints.

Another legal check on statements contained in radio advertising is found in the Federal Trade Commission Act. This Act, designed primarily to prevent unfair methods of competition in commerce, gives this Commission the power to proceed in respect thereof in the interests of the public. Deliberate misrepresentation and misleading advertising can be and has been stopped by this Commission. In a case under this law, the advertiser or manufacturer, not the radio station, would be held responsible for the statements made. As in the preceding case, complaint to the Commission will bring about an investigation. It should be understood that this law would only apply to exceptional cases in commercial health broadcasting. Any particular case should first be presented to one of the branch offices of the Commission in the West, located in San Francisco and Seattle.

The Food and Drugs Administration has control only over label and package advertising. The pending Copeland Bill will give the administration control over all advertising of foods and drugs, and will also bring under its control cosmetics and health appliances and curative devices of all descriptions. The features which caused such a storm of protest from radio, the press and manufacturers, have been amended. Group seizures of products have been ruled out except in the case of adulterated products. The clause holding the advertising medium, the radio or newspaper, responsible for the claims made, has been dropped, and the Bill pro-

poses to hold only the manufacturer and advertiser responsible. It is expected that the Bill as amended will pass Congress this session.

Your committee has attempted to find the best plan whereby we, as health workers, may work with the radio stations to use this medium for our purpose more effectively. We found that the radio workers know as little of the health field as health workers know of radio. They are confused by the many overlapping and paralleling organizations in the field of health. They are all anxious to aid the cause of health education, but may not show favoritism to any one group.

All the station managers stressed the need for organization of our educational activities, so that they might know a certain group was the accepted spokesman for the majority of the health agencies.

A survey of commercial radio advertising made by the Federal Communications Commission in 1932, indicates that educational institutions and groups do not make use of all the time that stations are willing to provide. At that time 95 per cent of all stations questioned said that this was true. Our survey indicates that this is still true. Every station but one was willing to give air time to a representative health group. The chain stations and others carrying sustaining health programs at present were willing to give more time to this subject, provided the subjects covered did not overlap their established programs. The other stations were quite willing to cooperate, provided the programs offered were of high interest value. The reason that so few stations have sustaining health education programs is that health workers have neglected to cultivate their assistance.

Your committee therefore believes:

That we must coordinate the educational work of all related health groups.

That we must study the material information offered by every health agency and group, and the publicity needs of each of these organizations.

That we must review this information with a view toward channeling through radio that which is suitable and proper to this medium.

That we must evaluate the proposed radio information and make proportionate allotments in our program planning for each field of health activity.

That we must devise a general program plan covering all radio stations and publicizing all fields of health activity.

That as a unified group, which is the accepted spokesman for all health agencies, we must present our plan to the many radio stations and work out with them a general and widespread program of health education on the air, that will have regularity and permanence.

Your committee therefore recommends that with your adoption of the proposed permanent Committee on Health Education: you make provision for a permanent Sub-committee on Radio; that divisions of this committee be located in San Francisco, Los Angeles, Seattle, Portland, and Denver, and in other important radio centers, with representatives in each community with a radio station; that provision be made for the allotment of funds for this work, to cover costs for typing and printing radio scripts, preparing electrical transcription programs, etc.; and that provision be made for this committee to make use of funds allotted to health education by various health agencies cooperating in this radio health education plan.

Your committee also points to the need for you, as individuals representing various health agencies, to work whole-heartedly with the proposed Committee on Radio in order that we may gain the benefits our unity of action will bring in this field.

Both the NBC and the CBS chain representatives we interviewed stressed the need for a national committee to bring about nation-wide radio health

programs on the chains. If we are to make use of these two most important units in radio, national planning should be considered.

Your committee therefore suggests that the Western Branch recommend to the parent organization, the establishment of a National Committee on Radio, with the purpose of actively engaging in broadcasting on a nationwide scale.

The Vitamin Saga

Vitamin A keeps the cold germs away
And tends to make meek people nervy.
B's what you need when you're going to
seed
And C is specific in scurvy.

Vitamin D keeps the bones in your knee
Tough and hard for the service on Sunday.
While E makes hens scratch and increase
the hatch.
And brings in the profits on Monday.

Now Vitamin F never bothers the chef
'Cause this vitamin never existed.
G puts the fight in the old appetite
And you eat all the foods that are listed.

So now when you dine remember these lines
If long on this globe you would tarry.
Just try to be good and pick out more food
From the orchard, the garden, and dairy.

Basophilic Aggregation Test in the Lead Poisoning Epidemic of 1934-1935*

CAREY P. McCORD, M.D., F.A.P.H.A., F. R. HOLDEN, Ph.D.,
AND JAN JOHNSTON

Industrial Health Conservancy Laboratories, Cincinnati, Ohio

THE automobile production year 1934-1935 marks the outstanding epidemic of lead poisoning in this country for at least the past decade. This epidemic appeared in the automobile industry, which industry has been substantially free from lead poisoning since the abandonment of the dry-sanding of wooden bodies painted with lead-containing paints. This preceding epidemic was described by Dean in 1924.¹ The present epidemic has prevailed among the several thousand workers engaged in automobile body manufacture.

Recent trends in body design have led to one-piece, all-metal bodies with non-air-resisting contours. The manufacturing processes entailed call for the filling in of all welding depressions and other indentations with a lead-tin alloy. This leads to the use of molten lead pots and torch work, which in turn are followed by various processes for the smoothing down of the leaded surfaces, including power grinding, hand filing, sanding, etc. As a result the atmosphere of these workrooms is polluted by harmful quantities of lead dust and lead fume. Occasionally as much as 1,100 mg. of lead have been encountered in 10 cu. m. of air, which

amount of air approximates the quantity of air breathed by the average workman during the usual work day. However, the usual amount of lead in this quantity of air has ranged from 10 to 40 mg.

This type of lead exposure has brought about a high incidence of lead poisoning, together with the much larger groups of workers in whom proof of lead absorption has been established but who have not suffered subjective injury and have not lost time from employment. It is not possible to state the extent of lead poisoning during the past 12 months in the entire automobile industry. If the figures obtained from studies in a limited number of plants may be extended to the industry as a whole, it is possible that as many as 4,000 workmen have been injured to some extent during the 1934-1935 automobile production season. At best this figure is an approximation, and further it is emphasized that by no means does this number represent only actual clinical cases of lead poisoning.

During the past 10 years there have been many affirmations that industrial lead poisoning is a waning disease. While in some measure this has been true up until 1934, the outstanding fact is that it is the severity of the affection that is waning, rather than the frequency. Very strikingly this has been borne out by the present epidemic.

* To be read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

As far as is known among the large number of cases, there have been no proved deaths, little profound encephalitis, very few instances of wrist drop or foot drop, etc. With certainty it may be believed that there have been milder degrees of neuromuscular injuries, encephalitis, etc. The outstanding and almost uniform manifestations have centered about involvement of the gastrointestinal tract, accompanied by excessive fatigability and blood changes.

Already the work conditions that produced this recent epidemic of lead poisoning have been modified in many plants to the extent that large numbers of additional cases of lead poisoning are unlikely. In some plants elaborate protective devices and procedures have been introduced. As yet no practical substitute has been found for the lead-tin alloy, inasmuch as certain other alloys that otherwise might be used may not be used due to prohibitive costs, undue shrinkage, etc. All in all, it may be stated that at least in some automobile plants the lead hazards have been brought under control.

This recent epidemic has provided us a long sought opportunity for the extended investigation of a diagnostic procedure first utilized by us in 1924.² Already a publication³ has been made on this recent experience up to the time that 1,600 tests had been carried out. At this time the results of nearly 8,000 tests are available for the appraisal of the method. This test is based upon the enumeration of the total number of basophilic containing cells in the blood, in distinction to the widely used procedure of enumerating preformed stipple cells, the value of which method is now somewhat questioned. The method as carried out is similar to that lately used by Jones and his associates.⁴ Since the basophilic formations as seen in the microscope do not exist as such in the blood stream and are artifactually produced in the

process of preparation and staining, we prefer to use the term "Basophilic Aggregations," which term uniformly appears in the subsequent discussion of this test and our experience with it, which now follow.

BASIC PRINCIPLES

In normal adult human life, the content of erythrocytes in the blood stream is maintained on a fairly uniform level by the orderly entry of new cells from the bone marrow replacing those that have been destroyed.

These new cells are essentially mature, only about 1 per cent exhibiting any of the several known characteristics of immaturity. In bone marrow, during the formative period of erythrocytes, an entirely different cytology takes place varying with the stage of development of the red cells. Readily there may be demonstrated nuclei, protoplasm, and basophilic substance. In due time a change not known for any other cells of the body occurs; a chemical (hemoglobin) replaces the protoplasm and the nucleus is extruded. The erythrocyte is then ready for its chief function in the circulatory blood. These phenomena are set forth admirably in Key's⁵ fundamental paper on erythrocytic cytology. The mechanism which liberates cells when mature and conversely retains undeveloped cells is not known. However, the functioning of such a mechanism is well established.

Under conditions in which toxic agents exert an action on bone marrow, and under other conditions in which physiologic demands are made, increased numbers of erythrocytes enter the blood stream. As examples of the former may be cited lead, benzol, toluol, xylol, possibly arsenic and chlorinated hydrocarbons, such as carbon tetrachloride; of the latter the effects of high altitudes constitute an obvious instance. The chief charac-

teristic of these liberated immature cells is the presence of basophilic substance.

Polychromasia (polychromatophilia), punctate stippling, and reticulation are but different manifestations of one phenomenon—the presence of basophilic substance. The exact form of this basophilic substance existing in the unaltered blood is little known. Probably the picture observed as polychromasia after staining is nearest to the natural state of this material. The impression furnished by all available evidence is that of thousands of ultramicroscopic particles in acid suspension, or possibly in their innate form in acid solution. Reticulated cells probably are produced only as a result of laboratory manipulation and thus while not being true artifacts are laboratory creations. With suitable laboratory facilities one is able to observe through the microscope the actual formation of reticular processes in cells not previously exhibiting such reticulation. Through variations in laboratory technic, the experimenter may produce at will in a single blood smear all the well known varieties of reticulation, as fragmented, anastomosing, wreaths, mossy forms, etc. If the artificiality of reticulation be accepted as fact, then such terms as “reticulocytosis” conceivably may be regarded as anomalous, in so far as these terms betoken the existence of reticular forms in the circulating blood. However, stippled cells are believed to exist as such in the unaltered blood. Through unknown processes, the ultramicroscopic particles observed as polychromasia or the basophilic materials in acid solutions, are caused to arrange themselves into masses characteristic of stippling. From the literature these concepts are well borne out in substantial publications, brief excerpts from which are now recorded.

Key⁵ notes:

If an individual reticulated cell be watched carefully during the process of staining, the

net can be seen to grow under the eye of the observer as though it were being formed by precipitation of the substance from the surrounding medium.

It is difficult to conceive that fixatives cause a definite network to break up into ultramicroscopic particles and become uniformly distributed through the cell (*i.e.*, polychromatophilia). Fixatives tend to fix intracellular products *in situ*. It is consequently felt that the conclusion is warranted that the reticular network as seen in supravitally stained erythrocytes is formed only during the process of staining and that no such structure exists in the unaltered erythrocyte.

My observations lead to the belief that the granules of punctate basophilia are formed of the same basophilic substance which in simple anemias gives pictures of polychromatophilia and that because of the pathologic process the substance is aggregated into small granules in the cell [punctate stippling].

With Wright's stain allowed to dry on a slide to which salt solution and blood is added, no polychromatophilia is seen but a definite basophilic reticulation slowly appears in the basophilic erythrocytes.

Basophilic substance (*i.e.*, as a term) is preferable to “reticular substance” since reticulations are artifacts due to the action of a stain on a substance distributed uniformly through the cell.

In Hawes's⁶ work no distinction was made between polychromatophilia and stippling, but when total percentages of the two were added the results corresponded with fair constancy with the total percentage of reticulated cells enumerated by other means on the same blood. Such differences as were encountered were attributed to differences in the delicacy of the methods used and not to any true excess of reticulated cells.

Jones⁴ observes: “This (basophilic) substance is demonstrated either in the form of polychromatophilia, punctate basophilia, or reticular designs, depending upon the staining method used.”

Basophilic substance long has been regarded as the foremost blood finding in lead poisoning, but to an overwhelming extent reliance has been

placed upon the determination of stippled cells. Recognition that polychromatophilia, punctate stippling and reticulation are but different aspects of the same material, should prompt the placement of greater diagnostic dependence upon examinations for the totality of erythrocytes containing basophilic material. Of the three forms of basophilic substance, stippled cells are the least common. The positive diagnostic significance widely attached to the qualitative finding of stippled cells in suspected lead poisoning is becoming more and more questionable; conversely less uncertainty is believed to attend the quantitative determination of all basophilic erythrocytes.

TECHNICAL PROCEDURE

The blood of normal human adults rarely contains more than 1 per cent of basophilic erythrocytes. The average in our experience lies between 0.4 and 0.8 per cent. With workers absorbing lead without clinical manifestations and in early lead poisoning, the percentage commonly ranges from 1.5 to 4.0 per cent, with occasional findings up to 20.0 per cent. The zone between 1.0 and 1.5 per cent represents the threshold, findings within which being open to doubt. In the absence of other pathology, any finding in lead exposed workers of, or in excess of, 1.5 per cent at once suggests the probability of lead absorption. Findings in excess of 2.0 or 3.0 per cent are to be associated with an increased imminence of clinical lead poisoning.

Search for these basophilic forms is best made in laked cells. When laking takes place some of the basophilic substance probably leaves the cell with the hemoglobin. The remainder, being insoluble in water, salines, and some stains, collects in masses, strands, and reticula, as laboratory artifacts. Such forms are far more visible than poly-

chromatophilic cells and are more numerous than stippled cells.

In our first work ² a thick, even blood smear was entirely laked. The number of basophilic aggregations in an average of many uniform microscopic fields was interpreted in relation to our clinical observations of the persons examined either as controls or as leaded patients. This procedure justly has been criticized as not readily transferable to others for quantitative work, since the making of uniformly thick smears by divers persons is most unlikely. Under rigid research conditions this earlier method will yield quantitative results but now is not the preferred procedure. The technic now employed is here presented:

The Sussmann-Weindel stain advocated by Jones is quite satisfactory when its several ingredients are pure. The formula is as follows:

Toluidine blue	0.5 gm.
Borax	0.05 gm.
Methylene blue solution (Loeffler's)	5 c.c.
Distilled water	100 c.c.

Our experience with this stain has been that it is not uniform from one batch to the next. Most of the trouble may be traced to the toluidine blue. Of six samples of this dye recently purchased by us from various supply houses, only one was found to be satisfactory.

A modified Manson's methylene blue yields more consistent results. The formula is as follows:

Borax	1.0 gm.
Methylene blue	2.0 gm.
Distilled water (boiling)	100 c.c.

The borax is dissolved in the boiling distilled water and to this is added the methylene blue. After filtering, this stain is ready for use and provides a stable, satisfactory, and uniform stain for at least 2 weeks. If used for long periods, a progressive formation of

FIGURE I. Schematic arrangement indicating fixed (x, x) and unfixed (y, y) portions of slide, together with counting procedure on uniform slide.

precipitate may appear. However, due to the low cost and ease with which this stain is prepared, we consider this a small handicap. This stain is less stable than the Sussmann-Weindel, but in our experience gives more trustworthy results.

Thin, even blood smears are made on slides and allowed to dry. The proper drying of these smears becomes important. If permitted to become excessively dry, that is, longer than 12 hours, some of the basophilic containing cells will not lend themselves to aggregation of their basophilic material. On the other hand, insufficient drying facilitates removal of cells during the staining period. Ordinarily the optimum time lies between 1 and 3 hours. Under peculiar industrial conditions, involving high temperatures and low

FIGURE III. Typical microscopic field from fixed portion of same slide as in Figure II, presenting unlaked, stained red blood cells. Lines of Whipple grid used as guide in counting may be seen.

humidity, or conversely high humidity, special consideration for the drying period may be required.

After drying, one-half of the slide is overlaid by a strip of filter paper, as set forth by Jones, and cautiously there is applied with a pipette or dropper the minimum amount of methyl alcohol C. P. (methanol, wood alcohol) required to moisten the filter paper until it clings to the slide. This is allowed

FIGURE II. Typical microscopic field from unfixed laked portion of slide presenting numerous basophilic aggregations.

FIGURE IV. Semi-schematic drawing of a basophilic aggregation in laked red blood cell. Manson stain. Magnification in original drawing: 17,000.

to dry until the filter paper becomes loose.

The slide is now submersed in a Coplin staining jar, containing the Manson stain, for approximately 10 minutes. The time is of minor importance since a readable stain may be had in 2 minutes, and on the other extreme it is impossible to overstain. After staining, it is necessary to wash the slides through 3 or 4 rinses of distilled water. In some cities tap water may be safely used for this purpose. Air drying of the slides is recommended.

The microscopic arrangements as used by us provide an oil immersion objective and a 10X ocular, which is fitted with a Whipple grid. The outer lines of this grid determine our microscopic field (Figure III). The average field in a good preparation contains approximately 150 red blood cells. Before counting, the slide should be examined for an area showing suitable distribution of the red cells. In the unfixed portion of the slide, customarily 10 consecutive fields in two parallel rows are counted, making a total of 20 fields, but in the more evenly distributed slide 20 consecutive fields. Then moving to the fixed portion of the slide, 5 appropriately corresponding fields are counted (Figure I). The basophilic aggregations are then expressed as a percentage of the latter.

Thus, if in the 20 fields counted in the unfixed portion of the slide there were found 76 B.A.s (Basophilic Aggregations), and if in the 5 fields of the fixed portion 1,000 red blood cells (or 4,000 in 20 fields), the obvious percentage is 1.9.

The physical features of the B.A.s are best presented in the accompanying photographs and photomicrographs (Figures II, IV). The color of the cells varies with the stain employed. A clear, brilliant blue is obtained with the Manson stain. A hand tally is used in the enumeration of the cells.

RECENT RESULTS

During 1934 and the first two-thirds of 1935, approximately 8,000 examinations were made, using the technic just described. The examinees represent employees in 16 plants and 6 different industries. Included in the 8,000 tests made are several hundred controls usually obtained from office groups. The lead exposed workers were distributed over the following industries: lead pigment manufacture, paint and other coatings manufacture, soldering, lead casting, lead oxide manufacture and application, and lead smelting. In some plants, but not all, concurrent determinations were made as to the amount of lead in the atmosphere expressed in terms of mgs. of lead per 10 cu. m. of air. In the aggregate, 416 quantitative lead determinations were made. The results from the basophilic aggregation tests have been correlated with the findings of the quantity of lead in the atmosphere breathed by exposed workers.

During 1934, basophilic aggregation tests were carried out simultaneously with stipple cell determinations, and in some instances with hemoglobin measurements and total red cell counts. Very early it was established that no consistent correlation was present. In many persons wholly unexposed to lead an occasional stipple cell was encountered and among lead workers approximately 90 per cent presented large numbers of stipple cells in the absence of clinical lead poisoning, and often after 3 months of no exposure to lead. The number of stipple cells in lead-using workers without clinical lead poisoning ordinarily was lower than 3,000 per million. The qualitative demonstration of stipple cells proved of no value in the diagnosis of clinical lead poisoning or in the making of decisions as to acceptability of men for continued work. Many workers regularly exhibiting stipple cells in

their blood smears passed through the entire automobile production season without illness and without any lost time. In similar fashion it was found that no significant diagnostic values resided in the routine determination of hemoglobin percentages or in total red cell counts. Over and over high percentages of basophilic aggregations were detected with no significant changes either in the hemoglobin or in the erythrocyte counts. For this reason all blood work other than the basophilic aggregation tests was abandoned as routine procedure in plant surveys, although complete blood work was carried out in the management of clinical cases of lead poisoning.

The trend of findings from 8,000 basophilic aggregation tests are now shown in three specimen tables.

Table I comprises the results from 25 representative controls. In establishing normal ranges of basophilic cells only such persons were utilized as

were known to be essentially unexposed to lead and definitely unexposed in industrial pursuits. Almost without exception control examinees present less than 1 per cent of basophilic containing cells.

In Table II may be found the results of 25 workers in an atmosphere containing lead to the extent of 14 mgs. per 10 cu. m. of air. In contrast to the control table just preceding, a fair number of these examinees present findings above 1.5 per cent. It is among workers having such findings as these that clinical cases of lead poisoning may be expected to arise. Almost uniformly it has been noted that the higher the lead content of the atmosphere the higher the percentage of exposed workers showing positive basophilic aggregation findings. On the other hand it has not been found that the percentage of basophilic cells increases with any uniformity in keeping with increases in the lead content of the atmosphere. An occasional worker may yield as high a figure as 10 or 15 per cent of B.A.s but this is not the rule and the majority of affected

workers regardless of the amount of the exposure will present positive findings in the range of from 2 to 6 per cent.

With the procurement of better work conditions, as reflected by lowered quantities of lead in the atmosphere, there occurs a corresponding diminution in the number of persons showing positive tests, although there is a lag of from 1 to 2 weeks before this drop may be demonstrated. This correlation between lead in the atmosphere and positive blood smears is reflected in Table III.

TABLE III

BASOPHILIC AGGREGATION TEST RESULTS ON WORKMEN BEFORE AND AFTER THE LEAD CONCENTRATION WAS REDUCED FROM 75 MG. PER 10 CU. M. OF AIR TO 4 MG. PER 10 CU. M. OF AIR. ELAPSED TIME: 35 DAYS.

This specimen material is characteristic of the entire investigation, with one exception. In one plant, manufacturing a great variety of pigment materials, lead poisoning was known to be present but the basophilic aggregation tests were not found to be in keeping with our general experience. The assumption is that because of the

multiplicity of chemicals manipulated some biological antagonistic factor interfered with the usual reaction of the embryonic red cell to lead.

The chief application of this test has been in the routine examination of large groups of lead exposed workers. The results of such tests have been utilized as a guide for the transfer of workers to less hazardous departments, in the appraisal of the degree of exposure in different departments, in determining the effect of preventive measures, and in the differential diagnosis between lead poisoning and conditions simulating this disease, but in routine work its greatest single value has been associated with the detection of malingerers. During this epidemic in some plants, as high as 90 per cent of all exposed workers have simulated lead poisoning presumably in order to be eligible for insurance and sick benefits during the nonproductive season in the automobile industry. In some instances this basophilic aggregation test has been accepted as a sufficient criterion for the weeding out of these malingerers.

GENERAL COMMENT

In persons exposed to lead, otherwise free from disease, the detection of basophilic containing red cells in percentages in excess of 1.5, and particularly in excess of 2 per cent, suggests lead absorption and the possibility of approaching clinical lead poisoning.

Inconclusive proof is available that this test may be positive after exposure to other substances such as benzol, toluol, xylol, arsenic, etc. Occasionally in infectious diseases numbers of basophilic aggregations above the usual may be found. Manifestly in anemias and other types of diseases involving the red blood cells, normal ranges may be exceeded.

The length of exposure to lead ap-

pears to have no significant bearing upon the basophilic aggregation findings. Two weeks' exposure is ample to bring about increased numbers of basophilic containing red cells. New workers employed alongside of workers employed for a longer period are prone to show a greater frequency of response than the older workers.

In prolonged chronic lead poisoning the test described appears to be of limited value. The recession in the number of basophilic aggregations may be definite in long existing lead poisoning even in the presence of frank manifestations. Under such conditions punctate stippling may persist.

In many publications the minimum amount of lead that may lead to lead poisoning is specified as from 1 to 2 mg. as a daily intake. While this figure may represent a primary threshold at which an occasional case of lead poisoning may arise, it is our experience that many hundreds of workers continue at employment in concentrations much higher without demonstrable impairment. Without denying the possibility that a daily intake of 1.5 mg. of lead may produce lead poisoning, the belief is expressed that the practical threshold may be considerably higher and in the general range of from 4 to 8 mg. At least, years of exposure to such concentrations have not led to a single recognized case of plumbism in several plants included in this investigation.

One of the practical advantages served by this test as described lies in the fact that large numbers of persons may be examined daily. In our experience, a single worker has been able to collect as many as 300 specimens per day. Laking, staining, and cell counting, subsequently carried out, necessarily must be at a slower rate, but on a single day, as many as 70 counts have been made by one experienced technician. This rate of work

stands in contrast to stipple cell enumeration, which if properly carried out ordinarily yields not more than 20 determinations daily.

SUMMARY

In the 1934-1935 epidemic of lead poisoning in the automobile industry, 6,900 basophilic aggregation examinations of the blood were made. In addition during this period 1,100 tests were made in other industries, thereby totalling 8,000 tests during the investigation. This number includes approximately 500 control examinations made upon workers unexposed to lead.

Positive basophilic aggregation tests, the method for which is described in detail, have served as an index for lead absorption prior to the appearance of clinical manifestations of lead poisoning. This test has proved to be of value in the diagnosis of early cases of lead poisoning. An approach to this test was described by us in 1924. Through technical improvements, made by others and by us, this procedure is now suited to application by any physician or laboratory carrying out any blood examinations.

The basic principle in the basophilic aggregation test is the enumeration of red blood cells containing basophilic substance, in contrast to the customary procedure of qualitative or quantitative examination for stipple or polychromatophilic cells.

The native state of basophilic material in unaltered red blood cells is not known, but in the process of laking and staining red cells this substance may be artificially aggregated into readily visible masses. In normal human adults, these aggregates rarely exceed 1 per cent of the total number of erythrocytes, but in lead exposed individuals the percentages ordinarily lie above this normal maximum, when considerable lead is being absorbed or when clinical lead poisoning is im-

minent. Findings of percentages above 1 to 1.5 per cent and especially above 2 per cent in persons exposed to lead at once suggest lead absorption and the possibility of approaching lead poisoning, or the actuality of early lead poisoning.

In chronic lead poisoning this test usually is not, but may be, positive. As lead poisoning progresses to extended chronicity, the reliability of the procedure diminishes. This test has been utilized in lead-using industries to determine the number of exposed workers absorbing lead, as some proof of existing lead hazards, as a guide for the transfer of lead absorbing workers to lead-free departments, as a measure of the efficacy of preventive devices and practices, and as a means for the detection of malingerers.

There are varied types of diseases leading to positive basophilic aggrega-

tion tests, but in groups of workers in lead industries, presumably normal except for the possible effects of lead exposures, the positive basophilic aggregation test stands in some relation to lead absorption and its subsequent action.

Anthrax from Infected Shaving Brushes

THREE years ago a consignment of 12 shaving brushes came into Lambeth (a district of South London) and found to be infected with anthrax. The health officer seized 11, but the 12th had been sold and could not be traced. Every one of the 11 was found to be infected with anthrax. The brushes had apparently come from Germany and were sold wholesale at the rate of 6 for 30 cents. The ministry of health issued a warning concerning the brushes to the hospitals and newspapers in the neighborhood. At last the brush has been found, but unfortunately as the

result of a fatality. At an inquest on a boot repairer, who died in the neighboring district of Brixton, the pathologist stated that death was due to anthrax and that the brush was freely infected with the bacilli and spores of anthrax. The health officer gave evidence that a man might use an infected shaving brush every day for 2 years with impunity until he cut himself and became infected. The coroner remarked that the only satisfactory feature about the case was the vigilance exerted by the health authorities.—London Letter, *J.A.M.A.*, Aug. 10, 1935.

Relationship Between Electrophoretic Migration Velocities, the Virulence and the Types of the Diphtheria and Diphtheria-like Bacilli

K. PIERRE DOZOIS AND K. F. RAUSS

Department of Bacteriology, University of Maryland School of Medicine, Baltimore, Md.; and State Hygienic Institute, Budapest, Hungary

THESE studies were made to ascertain whether the electrophoretic migration velocity measurements made on microorganisms grown on Löffler's medium for 24 hours might be of value in routine work for determining the virulence of the diphtheria and diphtheria-like bacilli.

METHOD

The diphtheria strains used were obtained from the collection of the Bureau of Bacteriology of the Maryland State Department of Health through the courtesy of C. A. Perry. The virulence determinations and the typing were made by C. A. Perry (work not published). For the virulence determinations the intracutaneous guinea pig method was employed, while types were determined by colony morphology and carbohydrate reactions. The electrophoretic migration velocity measurements were completed before information as to virulence and type was obtained.

The bacteria were grown for 20 to 24 hours on Löffler's medium, pH 7 to 7.4. The surface growth was removed by washing with distilled water, pH 7. The bacterial cells of this suspension were washed three times. After the last

washing the suspension was homogenized by shaking for 2 minutes with glass beads and filtered through a thin layer of cotton. The electrophoretic measurements were made within 24 hours after the suspension was prepared. Dozois and coworkers (1935) have shown that the bacterial suspensions may be kept as long as 48 hours at 5° C. without a measurable alteration of the zeta potential.

Measurements of the electrophoretic migration velocity—The Kunitz modification of the Northrop-Kunitz Microcataphoresis Cell (1928) was used with a Bausch and Lomb 8 mm., 0.50 n.a. 21X objective, a 10X eye-piece and a micro lamp. After the cataphoresis cell had been filled with the suspension the current was applied for 6 minutes before readings were made. This is sufficient time for the microorganisms to reach a maximum velocity. Twenty readings were made at the two stationary levels, *i.e.*, 0.21 and 0.79 of the inside depth of the cell. An applied potential of 118 volts was used; this voltage gave a potential drop through the cell of 2.5 volts. The results are expressed in terms of 0.05 mm. per time (in seconds) with 118 D.C. volts.

It was not found necessary to con-

vert these results into velocities in microns per second, for the velocities are not constant and depend on various factors of technic. The velocities per unit of time do not represent a basis for comparing these results with those of other workers. Comparisons of the electrophoretic measurements were made with the results of the virulence tests. The results of our observations are comprised in Table I.

DISCUSSION

As shown in Table I, from the standpoint of velocity, 3 zones may be differentiated. The smallest zone (the diphtheroid zone) ranging from 6.51 to 7 seconds includes the more rapidly traveling diphtheroids; the largest zone (the virulent zone), from 7.01 to 9 seconds, comprised the greater part of the virulent diphtheria strains with the medium velocity. The 3rd zone (the avirulent zone) which comprises most of the avirulent strains with the slowest velocity, ranges from 9.01 to

10.50 seconds. The lines between the zones cannot be sharply drawn.

The virulent and avirulent zones are divided into velocity classes. In class 1 are those microorganisms with a velocity between 7.01 and 7.50 seconds, in class 2, those with a velocity between 7.51 and 8.00 seconds, and so on through the 7 classes. The borderline between the virulent and avirulent zone falls between classes 4 and 5. Strains in the velocity classes near the border of the zones often cross that line. Two virulent strains are in class 5, and 3 avirulent strains are in class 4. On the other extreme toward the diphtheroid zone the same phenomenon may be seen. Five diphtheroid strains are found in class 1. The virulent diphtheria strains do not appear in the zone of the diphtheroids.

The 2 virulent strains which appear in the avirulent zone, 3 avirulent strains in the virulent zone, and the 5 diphtheroid strains in the virulent zone would have led to incorrect observa-

tions as to virulence had not the fermentation and intracutaneous tests been made. These above strains represent an error of 14 per cent, which is, doubtlessly, a greater error than that found by the intracutaneous test. This error is $3\frac{1}{2}$ times greater than that published by Jensen, Falk, Tonney, and White (1928), and approaches the results of Stone and Weigel (1929). The latter have found that there is not a sharp line between the virulent and avirulent strains and that there is also an interchange between them. Randall and Thompson (1931) have arrived at the conclusion that because there is no sharply marked line of distinction between the velocities of the virulent and avirulent strains electrophoretic methods of virulence determinations cannot be used in their present forms as a routine method.

A total of 70 strains were studied which represent all of the known diphtheria bacilli as well as the most common diphtheroids. As shown in the table, about half of the virulent strains appear in the velocity class near the border line which separates the virulent and avirulent organisms. The velocity distribution is sufficiently reliable to assume that at least 50 per cent of the strains of every series would belong to the borderline classes. Although the error found is but 14 per cent, in light of our experience, it may be as great as 50 per cent in other series.

There is another indication that the electrophoretic velocity method is not sufficiently advanced for routine work. Although Falk and his coworkers, and Randall and Thompson report that the avirulent strains migrate more rapidly than do the virulent, our findings are in accord with those of Stone and Weigel that the virulent strains migrate more rapidly than do the avirulent. These differences indicate that the potential difference of the bacteria depends on many and only partly known

factors. Falk, etc., and Randall, etc., used 48 hour old broth cultures for their determinations. Stone and Weigel have unfortunately not stated the medium they used. It is possible that the results we obtained were due to the fact that we used a solid medium (Löffler's medium) on which to grow the bacteria. It may be supposed that the electrophoretic velocity is not a constant feature of the bacteria, but depends upon factors of technic and environment. Although working under the same apparent conditions, a slight unavoidable change in technic might cause an alteration in the measured electrophoretic velocity.

As shown in the table, within each zone there is a certain tendency of the velocities toward the extremes. The gravis type apparently tends toward the extreme of the virulent zone, and the intermediate and the mitis types toward the avirulent zone. This trend suggests that the electrophoretic velocity of the diphtheria strains should be in accord with their virulence and the shift toward one or the other extreme should indicate the degree of their virulence. On the basis of this an attempt was made to determine, by means of the measured electrophoretic velocity, the variation of the virulence inside the three types (gravis, mitis, and intermediate) described by Anderson, Happold, and McLeod (1931). The errors in the electrophoretic velocity method were detected by studies of the intracutaneous tests.

In order to determine the variation of the virulence and the differences within each type, as well as the standard deviations and their differences, the mathematical mean of the electrophoretic migration velocity was calculated. The following are the results of these calculations:

1. Mean velocity of the gravis type (and its probable error) 7.94 ± 0.124 seconds
2. Mean velocity of the intermediate type

(and its probable error) 8.16 ± 0.151 seconds

3. Mean velocity of the mitis type (and its probable error) 8.11 ± 0.107 seconds

These figures indicate that the mean velocity of the gravis type is shifted toward the virulent zone; that of the intermediate type toward the avirulent zone, and that of the mitis type lies between the two. In other words, the gravis type would contain more strains with a higher degree of virulence than does the intermediate or the mitis type. These differences are, however, only apparent. "The significance test" shows the difference between the means was not significant (the difference between the gravis and intermediate 0.92σ , between the gravis and mitis 0.65σ , and between the intermediate and mitis 0.22σ). The even scatter of the strains as to their virulence distribution (migration velocity) was also ascertained by calculating the standard deviations of the type (standard deviation in order above; 1.33, 1.25, 1.35; differences 0.53σ , 0.18σ , 0.78σ). These calculations permit us to assume that if the velocity represents a degree of the virulence, the diphtheria strains studied show a corresponding virulence regardless of the type. Because our sample is small in regard to type distribution it does not permit us to draw final conclusions.

The distribution of the avirulent strains into types by means of colony characteristics and carbohydrate reactions offer figures of interest: 25 per cent of the avirulent strains belong to the mitis type, 19.05 per cent to the intermediate, and 13.33 per cent to the

gravis type. These figures offer further evidence for assuming the possibility of the variation of the virulence inside the diphtheria types.

SUMMARY

1. Electrophoretic measurements were made on 60 diphtheria and 10 diphtheroid strains, grown on Löffler's medium.

2. The diphtheroid strains showed the greatest velocity, the avirulent strains the least and the virulent strains represented a medium velocity between the two.

3. The borderline between the zones (diphtheroid, avirulent and virulent diphtheria) may not be sharply drawn because of the interchange of the strains located in the velocity classes in the vicinity of the borders.

4. Our determinations showed a 14 per cent error as compared to the virulence test carried out on guinea pigs.

5. Because of the errors, the electrophoretic method in its present form, cannot be used in routine work.

6. The variation of the virulence within the 3 diphtheria types was not demonstrable.

Public Health Expenditures in Selected* Cities by Nonofficial Agencies

JAMES WALLACE, M.D., F.A.P.H.A., AND LOUIS FELDMAN

*Committee on Administrative Practice, American Public Health Association,
New York, N. Y.*

IN previous articles of this series official public health expenditures in cities participating in the annual Inter-Chamber Health Conservation Contests have been analyzed. Consideration will now be given to public health expenditures of nonofficial agencies. The material herewith presented is derived from the same source—the Health Conservation Contests—but does not cover precisely the same cities as were included in the discussion of official expenditures for the reason that only a limited number of cities presented reasonably adequate data on nonofficial expenditures.

The services† covered in the totals for nonofficial expenditures are identical with those included in the discussion of official expenditures in preceding articles but in the case of nonofficial expenditures it has been impossible to analyze them by specific services because of the infrequency with which they were reported in sufficient detail.

In each of the preceding articles attention was called to certain limitations of interpretation which must be exercised in the use of material presented. Even greater caution should be exercised in the use of figures presented on nonofficial expenditures. A reasonably reliable figure on the average per capita expenditure for public health from nonofficial sources would be most desirable and useful. This is not possible from the data at hand. Figures presented in this article deal with a definitely limited group of cities, and the discussion will therefore be limited to nonofficial expenditures and their relationship to official expenditures in these cities. These figures must not be interpreted as necessarily portraying average per capita public health expenditures from nonofficial sources for the country as a whole. With these words of caution we may proceed to a discussion of the figures.

NOTE: This is the fourth article based on the Report of the Sub-committee on Current Practices of Health Departments of the Committee on Administrative Practice. The members are: Joseph W. Mountin, M.D., *Chairman*, E. L. Bishop, M.D., Louis I. Dublin, Ph.D., Allen W. Freeman, M.D., George T. Palmer, Dr.P.H., John L. Rice, M.D., and W. Frank Walker, Dr.P.H. Former articles by Dr. Mountin appeared in March and May *Journals* and an article by Dr. Walker in the July *Journal*.

* These cities were not selected voluntarily but rather by necessity. The group includes only those cities for which satisfactory data on nonofficial expenditures were available.

† Services included in the totals for both official and nonofficial expenditures are: administration, vital statistics, general sanitation, food, drugs, and milk, child health supervision (including maternity, infancy, preschool and school health services), communicable disease, tuberculosis, venereal disease and laboratory.

* Exclusive of hospitalization, institutional care, medical relief, garbage collection and disposal and capital expenditures and deficits.

† 1930 Census.

Official expenditures include Board of Education but not expenditures for physical education or health instruction by teachers.

Nonofficial expenditures are for the same services as official expenditures, the funds for which are derived from sources other than taxation.

Table I gives official and nonofficial expenditures for health services in certain American cities for the years 1930-1934. This table includes only those cities whose schedules for the Health Conservation Contest included reasonably complete data on both official and nonofficial expenditures. Because of the inadequacy of reporting nonofficial expenditures in cities of the lower population groups, only cities of over 50,000 population have been included in this table. The cities reporting for each of the several years are not always the same. As a matter of fact, only 27 cities reported consistently during each of the 5 years for which figures are presented.

This table indicates that during 1930 in a group of 55 selected cities (cities of over 50,000 population which competed in the Health Conservation Contest and submitted satisfactory data on nonofficial expenditures), official public health expenditures averaged approximately 86 cents per capita, and nonofficial expenditures about 59 cents. Official expenditures declined from a high of 88 cents in 1931, to a low of 78.8 cents in 1933, a reduction of 11 per cent, and then made some recovery, to 87.2 cents in 1934. Nonofficial expenditures reached a high of 59.7 cents

per capita in 1931, and declined to 43.6 cents in 1933, a reduction of 27 per cent, and then experienced a slight increase to 48.3 cents in 1934. It should be borne in mind that when comparing the group of cities in 1930 with the group in 1933 and 1934, somewhat similar, but not in all instances the same, cities are being considered.

A study of the individual cities which are included in this table indicates that the recovery noted in 1934 was due principally to an increase in expenditures in cities of over 500,000 population, and that this increase was not uniformly experienced in the smaller cities, particularly in the case of the nonofficial agencies.

Table II gives both official and nonofficial expenditures in the 27 cities which made reasonably adequate reports for each of the 5 years 1930-1934. This table quite obviously provides a more reliable basis for comparison than does Table I since only those cities which reported continuously for 5 years are included. On the other hand, fewer cities are being considered and the group is more highly selected from several points of view.

It will be noted that in this selected group of cities (cities of over 50,000 population which competed in the

TABLE II

† 1930 Census.

Official expenditures include Board of Education but not expenditures for physical education or health instruction by teachers.

Nonofficial expenditures are for the same services as official expenditures, the funds for which are derived from sources other than taxation.

Health Contest and submitted satisfactory data on both official and non-official expenditures for each of the 5 years) official per capita expenditures reached a high point of 105.5 cents in 1931, declined to 88.4 cents in 1933, a reduction of 11.9 per cent, and rose to 92.0 cents in 1934. Nonofficial expenditures reached a high of 66.8 cents in 1931 and declined to a low of 48.7 cents in 1933, a reduction of 27.1 per cent, and then rose slightly in 1934 to 50.6 cents.

In 1931, the high point for both official and nonofficial expenditures, the average total per capita public health expenditure in these 27 cities was 172.3 cents. Of this amount 105.5 cents, or 61.2 per cent, came from official, that is, tax supported sources; and 66.8 cents, or 38.8 per cent, from the non-official agencies.

In 1933, the low year for the combined expenditures, the average total per capita expenditure was 137.1 cents of which 88.4 cents, or 64.5 per cent, came from official sources and 48.7 cents, or 35.5 per cent, from nonofficial sources.

In 1934, total expenditures averaged 142.6 cents per capita, of which 92.0 cents, or 64.5 per cent, came from official and 50.6 cents, or 35.5 per cent, from nonofficial sources.

In addition to the limitations which have already been mentioned, there are a number of other points which should be considered in attempting to interpret these figures.

Both Tables I and II contain a more highly selected group of cities than even the remarks made with respect to them would seem to indicate. That this is true seems to be borne out by the fact that the official per capita expenditures as reported in these tables are appreciably higher than those reported in any of the tables of the preceding articles. This is due to the fact that the figures presented in this paper are limited to cities of over 50,000 population which have submitted reasonably adequate data on *both* official and non-official expenditures and, in the case of Table II, to the 27 cities which submitted these data continuously for 5 years. Both of these groups, and particularly the group in Table II, consist of those cities with the more highly developed health programs and the highest per capita expenditures. They are not necessarily typical of the country as a whole.

The figures presented on nonofficial expenditures even in this special group are probably somewhat higher than they actually would be if all the facts with respect to them were known. It

Official expenditures include Board of Education but not expenditures for physical education or health instruction by teachers.

Nonofficial expenditures are for the same services as official expenditures, the funds for which are derived from sources other than taxation.

is possible, for example, that duplication of figures may have occurred, such as where a voluntary agency is subsidized by an official agency and the amount of such subsidy may be included in both the official and non-official expenditures; overstatement of the proportion of hospital outpatient expenditures which should be included under the Contest definition of health

services; and the possible inclusion of expenditures which, according to the Contest's definition of public health, should not have been considered as public health services, such as a fund for purchasing milk, or certain elements of general medical service. While the amount of these errors, at least as expressed as a percentage of the total, would not in all probability

be great, it may make the figure somewhat higher than the true one. Unfortunately the exact extent of these errors cannot be determined for the reason that so few cities have reported their nonofficial expenditures in sufficient detail to permit the necessary analysis.

Table III, giving official and nonofficial expenditures in the same 27 cities as were presented in Table II, but divided according to geographic location, shows that the figures in Table II are largely determined by the cities of the northeastern area of the country and seem to account partially for the relatively high expenditures given in all tables. Figures by geographic location, although based on too few cities to give a reliable picture in all areas except the northeastern, parallel each other sufficiently closely to indicate that the trends as shown in Table II are probably consistent for the country as a whole.

While it would be impossible in the short space of this article to analyze the extent to which various health services are supported in whole or in part by nonofficial agencies, it seems quite certain that bedside nursing,* public health nursing, food and milk control, child health supervision, and tuber-

culosis control and prevention, constituted the most important contributions of the nonofficial agencies.

SUMMARY

In a selected group of cities having well organized health services and much higher than average total per capita health expenditures, the nonofficial agencies contributed in 1931 nearly 40 per cent of funds used for the support of selected health services considered in this article. In 1934 in this same group of cities the nonofficial agencies contributed 35 per cent of the funds used for the same purpose. Nonofficial expenditures averaged (in the group of 27 cities given in Table II) 66.8 cents per capita in 1931, and dropped to 48.7 cents per capita in 1933, a reduction of 27.1 per cent. While both official and nonofficial expenditures have experienced a drop since 1931, the decline in the nonofficial agencies has been much sharper than in the official agencies.

The possible inaccuracies which enter into the reporting of nonofficial expenditures and the incompleteness and inadequacy with which such reports are made point to a necessity for better reporting. There is need, in the nonofficial, as there is also in the official, field for better definitions of services, more nearly universal reporting of nonofficial expenditures, and for allocation of such expenditures according to specific health services.

* It is recognized that bedside nursing, if properly carried on, should include public health nursing, but the distinction is made here to differentiate between an organization which carries only bedside nursing from one that carries a health supervision service.

New Germany Teaches Her People

An Account of the Health Exposition of Berlin

H. E. KLEINSCHMIDT, M.D., F.A.P.H.A.*

Director, Health Education, National Tuberculosis Association, New York, N. Y.

HEALTH expositions have the reputation of being tawdry, superficial, and of questionable value. That reputation does not apply to the Berlin health exposition of 1935. It commanded attention without ballyhoo, interpreted health to the people without vulgarizing facts, and roused the people to a sense of citizen-duty in the "new" Germany.

German cities are "museum conscious." To operate an exposition is no great risk—attendance is assured, and skill in installing it is readily at hand. This one aptly called "Das Wunder des Lebens," was carefully planned well in advance. The long experience and expert workmanship of the German Hygiene Museum at Dresden assured the success of the enterprise from the beginning. The new government gave it strong support; excellent publicity made it known to all the people. It is no wonder that on some days the attendance reached 30,000, though the admission fee was fairly high. The exposition ran for 6 weeks, March 23 to May 5, 1935. Income from fees and from concessionaires was considerable, yet not enough to

meet entirely the enormous cost of manufacturing the exhibits and of manning the exposition.

One hesitates to describe the exposition in words; a suggestive outline must suffice. The visitor, after passing through one of four turnstiles, enters the Honor Hall, a vast, impressively empty vestibule. In front of him and occupying the entire wall he sees only a monumental relief frieze depicting the onward and upward sweep of a nation, led by a giant eagle. With no noise to distract his attention (for the floors are covered with carpet), with no objects in the hall except a few slender pillars from which hidden lights softly illuminate the hall, his attention is concentrated on this one picture in stone. Without being told, he "feels" rather than learns, that what he is about to see is of vital concern to the nation—a vast group-yearning toward a high goal and that he is a participant in it.

From this "experience" he next passes into a large, high ceilinged, dimly lighted room. An inscription in gold letters on the wall, quotes Augustinus: "Men marvel at the roaring sea, at flowing waters and at the spectacle of the heavens, and in their wonder forget the wonder they are themselves." On a pedestal occupying a rotunda is the transparent man, arms uplifted in the attitude of the "Praying Boy" celebrated by Goethe. There is nothing to divert the

* Traveling as a fellow of the Carl Schurz Foundation the author visited the health exposition held in Berlin in the spring of 1935. To Dr. Bruno Gebbard, who attended the meeting of the Association at Pasadena, and who was the scientific director of the exposition, he is indebted for numerous courtesies and lucid explanations.

attention from this one work of art. For a moment one enjoys the sheer beauty of the human body. Then the organs light up, one by one, and the concealed voice of the phonograph tells the story.

Passing out of this sanctuary, the visitor's eyes are dazzled by an array of colorful exhibits, many of them blinking or moving. The center area is like an open boulevard sweeping toward a wide staircase at the further end, which leads gracefully to a splashing fountain. This is the main hall and the heart of the exposition. Anatomy and physiology are the subjects taught, by means of models, instruments, and pictures.

Each subdivision is so designed as to convey atmosphere (*stimmung*) as well as exact information. The motif of the section on respiration, to cite an example, is lightness or airiness, with blue and silver, the predominating colors. The note of the section on circulation, is strength and elasticity; red and black are the dominant colors.

Ingenuous devices give a conception of area, extent, and function of the various organs. For instance, a cage made of tennis netting shows the volume of air breathed in a day; a large rectangular area on the ceiling, painted red, shows the surface that might be covered with the hemoglobin of one person; a table, the four legs of which are as many tibiae, support the weight of 20 men; piles of groceries and provisions show how much food one man consumes in a year; and so on.

Huge models of single organs, with careful detail, attract the eye. A giant ear rocks back and forth to demonstrate the mechanism of the semi-circular canals; an eye of the same proportions offers one an opportunity to see how the lens reflects images on the retina; a huge brain fitted out with push buttons shows what parts of the body each section of the brain

The Transparent Man

regulates. There is a "smelling table" where one can test his sharpness of scent; a skin-color scale with a mirror arrangement so that one may classify his own complexion; a dozen or more respirators for those who wish to test their lung capacity. There is an apparatus for testing color perception and, incidentally, the technician in charge is gathering valuable research data on color-blindness from the hordes of people who come for a tryout. To "do" everything in this hall in a hurried tour requires at least an hour; to study and understand it all would easily consume 4 or 5 solid hours of a nimble-witted person's time, in spite of the fact that the ideas are skillfully portrayed so as to be grasped easily and quickly. Much of the material in this hall is a duplication of the contents of the Dresden Museum, though some of the exhibits are improvements, and some entirely new.

The visitor passes from this hall up a broad stairway to a balcony restaurant, where, while refreshing himself, he surveys the kaleidoscopic yet orderly display he has just visited.

Hard by the main hall is the Microvarium, an enclosed arena, the cylindrical wall of which is the screen on which epidiascope pictures are shown in succession. In the center of the room and elevated about 10 feet is the laboratory where biological specimens are preserved and prepared for the 'scope. A gallery surrounding the laboratory is the stage for 8 epidiascopes, each operated by a technician. As the specimens, alive and squirming, are shown on the screen, one after another, an attendant explains them to the group of some 30 persons passing along the wall.

The next great hall has to do with race hygiene; "The Carriers of Life" it is called. Again the visitor is "put in tune," this time by a unique bell tower made of rough hewn timbers and rising loftily out of a semi-enclosed area, the boundaries of which are marked off by symbolical bas-reliefs of heroic proportions. Every 5 minutes

a huge hour glass in the lower compartment of the open tower, its sand having run out, turns over. It marks the death of 7 Germans. But instantly a nursery song rings out from the set of porcelain bells in the upper tower. Cheerfully these announce the birth of 9 German babies. Again and again the visitor hears the tinkle of the bells—forcefully reminding him of Germany's vital statistics.

The rest of the exhibits of this hall, with a few exceptions, do not compare favorably from a technical standpoint, with those of the main hall. The exhibits are crowded, sometimes dull and arranged in poor taste. Posters, none too well lettered, sermonize too much, and complicated organization charts confuse. The reason for this inferior exhibit technic, one surmises, is that this hall represents the handiwork of newer government personnel, who have not yet had much experience in graphic display. The subject matter deals

Vestibule to Exhibit on "The Carrier of Life" with Bell Tower

primarily with race hygiene. Eugenics charts and family trees abound. Sad galleries of unfortunate biological misfits—idiots, people with heritable deformities, incurable criminals—drive home the logic back of the new sterilization laws. The anti-Semitic policy is meticulously explained. Exhibits depicting Germany's falling birth rate betray what a sore problem this is to the new state; and, as a corollary what Germany expects of her young matrons is made clear in no uncertain phrases. To a foreigner interested in the present psychology of the German people and in the methods of public propaganda bureaus, this hall is, of course, a treasure house and more illuminating than pages of printed matter or folios of documents.

Public health occupies a hall called "The Maintenance of Life." It attempts to show the facilities of the government, including occupational therapy and curative medicine as well as the sanitary and educational activities of the Nazi party.

Another great hall deals with the emigration problem. In East Prussia, one learns, there is much unused land and a shortage of inhabitants. To populate this area the government offers homesteads to married couples of good heritage (as interpreted by the government) who have a desire to rear large families. In this hall there is a full sized model of the house that is offered by the government to young married persons, fully furnished, including even growing fruit trees and a cunning family of goats. Here, a number of the public welfare projects are also shown in good technic.

In the next hall are the commercial exhibits and these are much like those we see in America. Firms dealing in foods, clothing, household equipment, and so forth, occupy booths, distribute samples, and cry their wares. Originally there was some question as to whether

commercial concerns should be permitted to exhibit, but the management decided, wisely I think, to include them. A "health" show, an official explained to me, would attract the health cranks, but the lure of free samples, attractive displays of furniture, food, and what not, brings in the mothers and fathers, many of whom would not have come for a health exhibit alone.

IMPRESSIONS

A few impressions which strike the American (prejudiced by past experience with health expositions) may be worth noting. First there is the excellent advantage taken of open space. Space is valuable and the temptation of the exhibitor is to "cover" every inch of it. The German exhibitor, however, uses space to direct attention to what is important. The vast emptiness of the vestibule (Honor Hall) is impressive and one's attention is concentrated on the frieze. The chapel-like space occupied by the transparent man creates an attitude of respect, if not awe. The broad avenue looking toward the rising staircase and the fountain, enhances the effect of commotion and liveliness of the exhibits which bound it on each side.

All floors are covered with a silencing matting. One is not disturbed by the clatter of countless feet, or tempted to litter the floor with pamphlets and orange seeds. This one nicety of technic, though it cost thousands of dollars, is well worth its price and is cited as an example of the attention to detail.

The attempt always to establish atmosphere in consonance with the particular exhibit is, as mentioned before, praiseworthy.

The opportunity to press buttons, pull levers, test one's physical abilities and in general to "play" with the exhibits is a grateful relief to the sight-

A Section of Exhibit on Respiration. Netting and Color Scheme of Silver and Blue Are in Keeping with the Nature of the Exhibit

seer who has walked miles of musty galleries dotted with "don't touch" signs.

The Microvarium is a unique feature, instructive and fascinating. The conducted tours, the illustrated lectures, and the personal demonstrations have fine pedagogical value.

The opportunity to rest in the refreshment halls and the several movie auditoriums is appreciated by the foot-weary.

The excellent advertising and publicity campaign was equal to, if not better than, similar efforts we customarily make in the United States, and served to spread information widely among those who never saw the exhibit.

VALUE OF EXHIBIT

An attempt to appraise the political and social value of the exposition as a whole, would be too ambitious. It is enough to say that the success of the enterprise as an exposition was unquestioned, for it reached some three-

quarters of a million people in 6 weeks, entertained and instructed them, and undoubtedly stimulated an interest in the aims of the new government. Limiting the discussion to that part of the exposition which had to do with scientific biology, what shall we say as to the ultimate value of the teaching methods employed? In America some of us are skeptical of the purely informational type of teaching, even when that is coupled with appeals to the emotions. What springs of motivation, we may ask, are set going by a knowledge of how food is digested, or how enduring the heart is, or why epileptics should be sterilized? Will an understanding of endocrine glands safeguard anyone's health? Is it useful for anyone to know that his bowels are 7 meters long, or that his capillaries, if laid end to end would reach from Budapest to Wherever?

All of these facts are interesting, but what is accomplished by teaching them? Certainly for a substantial proportion

of the population (more in Germany than in America, perhaps) this kind of teaching is extremely valuable, in that it awakens interest, supplies basic information in easily understood form, and builds a substantial foundation of knowledge on which it will be easy later to construct a well rounded health attitude. The biologic knowledge so attractively presented, makes people receptive to modern medical ideas and lessens the resistance to public health practices. To an extent, it serves also to help people discriminate between sound and unsound health advice; to distinguish between scientific medicine and quackery. Above all, it impresses upon even the most casual the

"Wonder of Life," Admiration for the marvel of the human body, reverence for the mysterious thing we call life, is worth cultivating in this surfeited generation.

The expense of this kind of health education is admittedly heavy, as compared with the publicity campaigns common in our country. However, the greater permanence of the impressions made, the greater number of people reached and interested, doubtless justifies the expense. It is the kind of project that might best be financed by a bequest or foundation, the donors of which have faith in the power of knowledge, and generosity enough to let others reap where they have sown.

Cooking of Vegetables

FOUR series of samples of spinach, two of mustard, one of cabbage, and one of turnip tops were cooked by four different methods, and the losses in iron, copper and manganese, and total solids were ascertained. The methods employed were boiling in 2 liters of water; boiling in 4 liters of water; steaming; cooking under 15 pounds pressure. The average losses for iron for these methods were, respectively, 27, 34, 4 and 8 per cent; for copper 29, 34, 9 and 16 per cent; for man-

ganese 32, 48, 6 and 13 per cent; for total solids 24, 32, 6 and 11 per cent. It was found that the greatest losses were obtained when the vegetables were boiled, while the smallest losses occurred with steaming or pressure-cooking methods. As a means of introducing these minerals into the diet, steaming and pressure cooking are, therefore, to be recommended in the preparation of vegetables.—F. Bartow Culp, and J. E. Copenhaver, *J. Home Econ.*, May, 1935, page 308.

Standardization of the Methylene Blue Reduction Test by the Use of Methylene Blue Thiocyanate*

H. R. THORNTON, PH.D., † AND R. B. SANDIN, PH.D.

*Departments of Dairying and Chemistry, University of Alberta,
Edmonton, Canada*

SINCE the first use of methylene blue reduction as an indicator of bacteriological quality in milk, fluid milk supplies on this continent have undergone notable improvement. Moreover, during this period it has been shown that the inaccuracies in the test increase with increasing reduction times.^{6, 8, 9} An effort to minimize these inaccuracies is, therefore, worth while.

Because of the extensive use of this test in milk control activities, it becomes necessary to duplicate frequently the standard tablets of methylene blue certified by the Commission on Standardization of Biological Stains and recognized by the American Public Health Association in *Standard Methods of Milk Analysis*.¹ This duplication involves not only the creation of standards but also the purification or, at least, the determination of purity of the dye. Clark, Cohen, and Gibbs² review the difficulty, if not the impossibility, either of purification or of determination of purity of methylene blue chloride, the methylene blue salt used in these tablets.

The nearest present approach to an absolute color standard in this test is that the milk should be colored a robin's egg blue. Among 6 workers in this institution, each of whom has had considerable experience with the test, there was no unanimity of opinion as to what depth of color in milk constitutes "robin's egg" blue. At the request of the Chairman of the Commission on Standardization of Biological Stains an attempt has been made to develop more exact standards.

Drew and Head³ prepared methylene blue thiocyanate which crystallized from aqueous solution—but carrying no water of crystallization—with almost 100 per cent purity. This salt, therefore, seemed to offer some attractive advantages over the chloride and gave promise of being a satisfactory means of standardizing the methylene blue reduction test. The present authors prepared by a simple process¹⁰ methylene blue thiocyanate and tested it as a substitute for methylene blue chloride.

METHODS

Standard Methods of Milk Analysis was followed as closely as possible in the reduction test technic and reduction times are reported in hours and minutes, 1:15 meaning 1 hour and 15

* To be read at a Joint Session of the Laboratory and Food and Nutrition Sections of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

† Associate Referee, Committee on Standard Methods for the Examination of Dairy and Food Products.

minutes. Three dyes were used as follows:

1. *American*—The standard American Tablet, lot 2,360, purchased in the United States not later than 1924, one tablet being dissolved in 200 ml. of distilled water of which solution 1 ml. was added to 10 ml. of milk.

2. *Thiocyanate*—Methylene blue thiocyanate prepared by the present authors and used in varying concentrations.

3. *Danish*—Tablets purchased from Blauenfeldt and Tvede, Copenhagen, not later than 1916. Aqueous solutions of these tablets were added to 10 ml. of milk in a concentration identical to that used in Europe with 40 ml. of milk.

REDUCTION TIMES, POTENTIALS, AND POISING ACTION

When methylene blue thiocyanate is added to milk in a concentration giving the same depth of color as is observed in the standard test, the reduction times of the thiocyanate and the chloride are identical.¹⁰ These results were verified by a number of laboratories in the United States and Canada to which samples of the thiocyanate were distributed through the courtesy of the Chairman of the Commission on Standardization of Biological Stains.

No essential difference was found between the oxidation-reduction potential ranges over which the thiocyanate and the chloride reduce in milk or in aqueous solution on titration with titanous chloride. The poisoning action of the former dye is no greater in milk than that of the latter.

CONCENTRATION

In 1924 Hastings⁴ reported that the Danish technic resulted in a depth of color in milk the approximate equivalent of 1 part of crystalline methylene blue chloride (of unreported purity) in 200,000 parts of milk. When 5 Danish tablets were each dissolved in 200 ml. of water the aqueous solutions varied in color depth between 67 and 100 color units. The American tablets were found to be 40–46 per cent of their

intended strength. It may be assumed, therefore, that in the standard American test the dye concentration in the milk is approximately 1:465,000.

In the present study aqueous solutions of methylene blue thiocyanate were prepared with concentrations of 1:20,000. Duboscq colorimeter comparisons of these solutions with aqueous solutions of Danish and American tablets were made. When 4 Danish tablets were each dissolved in 200 ml. of distilled water, the concentrations of the solutions in terms of methylene blue thiocyanate were as low as 1:4,761 and as high as 1:4,000, the average being 1:4,440. By computation the concentration of dye in milk in the test as carried out in Europe would vary between 1:195,201 and 1:164,000, the average being 1:181,050.

When compared with thiocyanate in a similar manner American tablets when dissolved in 200 ml. of distilled water varied in concentration between 1:69,561 and 1:60,377, the average of 5 being 1:64,468. By computation the concentration of dye in milk in the American test varies between 1:765,215 and 1:664,147, averaging 1:709,148. This variation is, therefore, greater than 15 per cent. Working independently and using dye from two different preparations the writers were able to check each other with respect to methylene blue thiocyanate concentrations to within 3.25 per cent.

When methylene blue thiocyanate was added to milk in a concentration of approximately 1:700,000 the same depth of blue resulted as is observed in the standard American test. Burkey reports⁵ that the concentrations which would more nearly compare with the standard American solution in milk were 1:480,000 and 1:560,000 respectively for two preparations of methylene blue thiocyanate. No attempt is made to explain the discrepancies in the results of the three groups of

workers but the difficulty of establishing a color standard based upon the depth of blue in the milk is at once apparent.

That the milk was lighter in color than expected was noted immediately the original tablets were placed on the market. This lack of depth of color gives rise to more serious trouble in Alberta than in any other area in which the writers have had experience. Practical operators of the test frequently use 2 and, at times, 3 ml. of the standard dye solution per 10 ml. of milk. There can be no question of the necessity for increasing the dye concentration in the test in this province. As Hastings⁴ has pointed out there seems to be no reason for accepting on this continent the European standard of dye concentration. The amount of dye used should be the minimum required to give a sharp end-point because increased concentration results in increased poisoning and lethal actions. We are of the opinion that a concentration of 1 part of dye to 300,000 parts of milk is satisfactory.

There is a present and growing need for standardizing the methylene blue reduction test as applied to sweet cream. As a step in this direction Macy⁷ recommends using a dye solution of triple strength. We have found that when methylene blue thiocyanate is added to cream in a concentration of 1:300,000, the color approximates rather closely that obtained in the technic suggested by Macy. It is advantageous to use the same dye solution for cream as for milk.

This increase in dye concentration will result in increased reduction times for most milks. The average increase for 25 milks of varying bacteriological quality was found to be 30 minutes when a methylene blue thiocyanate concentration of 1:300,000 was used (Table I). The differences may be due to greater lethal and poisoning action or color depth. Because the increased re-

duction time tends to be constant in all classes of milk, greater depth of color may be the main factor.

TABLE I

AMERICAN AND DANISH REDUCTION TIMES COMPARED WITH REDUCTION TIMES OF METHYLENE BLUE THIOCYANATE IN A CONCENTRATION OF 1:300,000

RECOMMENDATIONS

Exact standards for the methylene blue reduction test are becoming increasingly important. The inadequacy of the present empirical dye standards rests largely upon the difficulty of purification and determination of purity of methylene blue chloride.

Therefore, it is recommended that—

1. Methylene blue thiocyanate be substituted for methylene blue chloride in the standard tablets used in the methylene blue reduction test because of the reproducibility of the former dye.

2. One part of dye to 300,000 parts of milk be adopted as the standard concentration in this test.

Control of Rabies

HERETOFORE reliance in the control of rabies has unwisely and almost exclusively been placed in regulations which were difficult of enforcement. Future action, to be effective, must embrace educational efforts, primarily involving the dog owner but also extending to the general public. It is also to be hoped that success may be reached in preparing an effective vaccine against canine rabies.

Inasmuch as the muzzling of dogs, as a practical measure, is attended by difficulties, while leashing as a substitute is now on trial, the responsibility for bites should be placed squarely upon each dog owner. In any event, a city should be fully compensated for its financial outlay in preventing human and canine rabies. An adequate pro-

gram includes persistent, all-year effort in ridding the community of stray and unlicensed animals. For this purpose a sufficiently large individual dog tax should be imposed.

The writer believes that each person bitten should receive compensation, whether the bite is provoked or unprovoked. A dog bite, frequently involving pain, fright, torn clothing, a doctor's bill, and sometimes hospital treatment, is a distressing experience. Moreover, a course of prophylactic injections is an ordeal, particularly for children.

If the owners of biting dogs were sufficiently penalized, there would be a marked and rapid reduction in occurrences.—Robert Olesen, *Public Health Rep.*, Aug. 16, 1935.

Campaign Against Tuberculosis in College Students*

CHARLES E. SHEPARD, M.D.

Director, Men Students' Health Service, School of Hygiene and Physical Education, Stanford University, Calif.

THE campaign against tuberculosis is beginning to receive the serious attention of college administrators and college physicians. Prevention and early identification of tuberculosis presents a challenge to physicians who are interested in the prevention and early care of illnesses which bring disability upon students. A college education represents considerable investment of money and educational resources which cannot be realized in terms of disabling illnesses or premature cessation of the college course. Conditions imposed upon the boy or girl in college who breaks down with tuberculosis before graduation cause serious economic losses to the individual, to the college, and to the community. Since there are nearly 1,000,000 young men and women now attending our American colleges and universities, we are justified in asking what the colleges can do, and what they are doing, to reduce such tragic accidents as tuberculosis.

Although most students live healthy and well adjusted lives in college, there are certain factors in the environment which may encourage the development of tuberculosis. Important points in the tuberculosis prevention programs of our associations, such as, regulated living, adequate food, rest, sleep, and

freedom from stresses are sometimes not observed by college students. These young people are at an age and in an environment where the rules of healthful living may be loosely observed and where guidance from parents and the family physician is often not available. Academic competition is keen; ambition for accomplishment is high; and in these days there is often the need to carry outside work for self-support. There is furthermore a tendency to seek medical advice late rather than early. The college should therefore provide some form of medical supervision which will guide the student toward early medical care and a closer observation of those health rules which help to prevent tuberculosis.

The college age should be further emphasized as an age where tuberculosis is still claiming many victims. This disease causes more deaths between the ages of 15 and 45 than any other disease, with actual deaths reaching the high point for all ages between 20 and 24. Mortality rates show a slightly different picture, but here again the death rates increase rapidly between 10 and 20 and the high point for women is between 20 and 24. We are all familiar with the striking decline in death rates from this disease in recent years, and there has been a consequent decline in rates of the young adult age groups, except that the decline has been less for young women

* Read at the Sixth Annual Meeting of the Western Branch, American Public Health Association, in Helena, Mont., July 1, 1935.

than for young men. A study of the percentage decline reveals that the greatest reductions have occurred from birth to 14 years, and in the age groups from 25 to 64, while the smallest decline has occurred in the aged and in young people between 15 and 24. This is the age group in which life holds the greatest promise, the present seems happiest, and the future brightest. In this age group the decline in deaths has been too small and here the present and future campaign against tuberculosis should be concentrated.

It might be concluded from these statements that colleges must be sending into sanatoria and into the care of chest specialists, great numbers of victims each year. Since this is not true, we might assume that the number of undiscovered cases in colleges is fairly large. Preliminary studies in certain colleges indicate that such is the case and show that the tuberculosis problem is one which presents to the college a serious responsibility and to the college physician a worthy challenge.

Colleges are meeting this responsibility as a part of a more general responsibility for the health of their students. Many colleges now have established health programs set up primarily to maintain and protect the health of students. The extent of activities in these programs depends upon local needs and resources of the institution, but all carry the following general activities: prevention of the spread of communicable disease, protection of the student against disabling illness or injury, formal and informal programs of health instruction, and encouragement of students toward the establishment of good health practices. These activities have become the functions of several departments or schools of the college, such as, the College Public Health Service, the Student Health Service, Department or School

of Hygiene, and the Department or School of Physical Education. In some colleges these departments are combined in one school, thus centering all health activities and services under one roof.

The need for adopting programs of prevention has been the outcome of rather discouraging experience with case finding in colleges. We have learned that few early cases of tuberculosis will be found if we depend upon the student with early symptoms to report. Too often when he reports to the Health Service with symptoms he is found to have a well advanced lesion, which means a long period of illness for him and exposure of his associates over a period before the lesion was recognized. In the past 2 years at Stanford University, with a health program which encourages the students to report early, we have picked up only 3 early cases of tuberculosis among those coming with symptoms. Two of these reported because of hemorrhage. Moderately advanced lesions, or lesions with cavitation, were found in all others who reported because of symptoms. On the side of the prevention program, to the contrary, which consists in giving tuberculin tests to all contacts, to all who give suspicious histories, or who have suspicious physical signs, and to special groups, with X-ray studies of positive reactors, we have discovered 5 students during the same time with incipient disease who had not complained of illness. One of these, a medical student, who received the test and X-ray as a routine part of the examination required on admission, was found to have an advanced lesion with cavitation, yet had no symptoms, and no physical signs. We are therefore convinced that the greatest opportunity lies in discovering the disease *before* the occurrence of symptoms sufficient to bring the patient to the doctor.

TABLE I

INCIDENCE OF TUBERCULOSIS IN STUDENTS OF 21 COLLEGES AS REPORTED FROM 1932-1934

Student Health Service physicians from over 200 colleges in the country are members of a national organization known as the American Student Health Association. Three years ago this association set up a committee composed of Dr. Ferguson of Western Reserve University, Dr. Myers of the University of Minnesota, and the author to study the tuberculosis problem in colleges, and to inaugurate a campaign against the disease which would receive the unified support of members of the association. This committee, working under the advisory direction of Drs. Kleinschmidt, Long, Chadwick, and McPhedran, has had an unusual opportunity to promote and correlate a unified program of prevention against tuberculosis in colleges. College physicians have been encouraged to set up definite control programs with uniform attention to special history forms, physical examinations, including tuberculin testing, and X-ray studies of contacts and of special groups, and follow-up studies of suspicious cases by chest specialists. Many colleges have already adopted this program and are discovering cases which had previously escaped attention. Others have started modified programs made necessary by

limited resources and facilities, but are demonstrating the need for more intensive study.

In addition to its opportunity to promote the college campaign against tuberculosis, this national college project has broad research possibilities because it is under centralized control which will produce an increasing uniformity of procedure and relatively high reliability of results. Dr. Long has been the first to demonstrate its effectiveness as a research mechanism in a study on the use of purified protein derivative in college students. Among other research problems in this connection which are now being considered in various colleges are the following: The relation between positive and negative tuberculin reactors and the incidence of subsequent disease; incidence of disease by sex at the college level; effect of strenuous athletics on incidence; incidence in students in professional schools compared with general student groups; unification of methods of X-ray reports; studies of the relation between the presence of calcification and subsequent disease.

Many reports on these prevention and research programs are now coming in to the Committee on Tubercu-

CHART I

losis of the American Student Health Association, from which we present a few preliminary trends. These results are seen in Table I and Chart I. Progress to date indicates 10 times as many cases of tuberculosis reported from colleges where active control programs are being conducted than where little is being done about the problem. We find that the incidence of tuberculosis and of positive tuberculin reactors varies considerably in any given college from year to year and that some colleges seem consistently freer from disease and infection than others. The incidence of infection seems to be slightly higher in men than in women students, but the incidence of disease is slightly higher in women. The percentage of positive tuberculin reactors varies greatly in colleges located in different parts of the country. Thus, Iowa State College reported only 12 per cent reactors in almost 3,000 students tested in 1933 while Yale reported 62 per cent reactors in 3,000 students tested in 1932. The reports in general indicate that positive re-

actors are more frequent in colleges which draw students from more densely populated districts, such as the University of Pennsylvania and Yale University, than in colleges drawing chiefly from rural districts. (Dr. Halvorsen of the University of Idaho tells me that almost no students from the rural districts in Idaho react to tuberculin, while most of those from the mining districts in southern Idaho are positive reactors.)

From the combined reports of 48 colleges for the 2 years 1932-1934, representing a total of 33,151 students tested, the general average of positive reactors was found to be 31 per cent.

These are probably not as accurate as forthcoming reports will be, since there has not been complete uniformity in tuberculin used or in dosage. Most colleges have been using the Saranac tuberculin in 1/10 mg. doses. We are now recommending the use of P.P.D. in 2 doses, which should give us more reliable and comparable results. It is unfortunate that so few data are available either from people of college age

not attending college or from younger groups similarly distributed throughout the country. The closest comparison with data from younger groups comes from a National Tuberculosis Association study in which groups of children in various states are being tested with MA-100. Miss Jessamine Whitney has recently sent me a table summarizing the positive reactors found in 101 groups tested in 18 states. Twenty-five per cent of almost 3,000 children between 10 and 14 in this study reacted positively, and 27 per cent of 1,400 between 5 and 9 reacted positively. These percentages are almost the same as for college age groups, which is rather surprising in view of the high morbidity and mortality at 20-24 as compared with the 10-14 age group. These discrepancies may be due to difference in materials and dosages and to the wide local variation in numbers of reactors which are known to occur.

The incidence of disease reported from different colleges also varies greatly, probably depending largely upon the effectiveness of the local program and perhaps on geographical location, so that we are not justified in drawing conclusions from these reports. Agnes Scott College in Georgia reports only 1 girl with tuberculosis in 450 carefully studied, while Iowa State College (where tuberculin reactors are relatively few) reported 48 cases with an enrollment of almost 3,500 students, slightly over 1 in every 100 registered. From the combined reports of 21 colleges for the 2 years 1932-1934, representing over 110,000 students enrolled, 688 cases of tuberculosis were reported. This indicates a general average of 1 case in every 160 students enrolled, or a rough morbidity rate in these colleges of 625 per 100,000 for each year. Here again we have no comparable data on case finding studies on non-college age groups, so that we

do not know whether college students are more subject to the disease than other groups of young people. No comparisons can be made with morbidity rates in these age groups in states where tuberculosis is a notifiable disease, since reporting of cases is notoriously poor. It is also very probable that as case finding studies in colleges become more effective, more cases will be discovered. This will proceed to a fairly constant level which then would only be lowered finally as control measures became more effective in other parts of the general population.

It is quite certain that ideal campaigns against tuberculosis will not be reached in many colleges because of limitation of facilities. Such a program will be started at the University of California and Stanford University next year under the auspices of the San Francisco and Alameda County and California State Tuberculosis Associations. This program will comprise histories, physical examinations, and skin tests on 2,000 new students with X-ray studies of positive reactors, tuberculin tests repeated each year for those who reacted negatively the previous year, again followed by X-ray studies of the new reactors, this to be carried on through the 4 years of college and into graduate years of professional schools. Efforts will be made to contact students in this group over a 10 year period from next fall. In all suspicious cases there should be careful clinical follow-up. This study and follow-up procedure can be carried on with greater effectiveness in Student Health Services than among the general population because of the ease with which contacts can be made with student patients.

SUMMARY

During our span of life we each pass through certain periods when tuberculosis is to be specially feared. Tuber-

culosis is pertinently a problem of the ages from 15 to 44 as shown by a study of the death rates, and is especially to be feared in the years of late adolescence and early maturity—the college age. Realizing that people of college age are particularly susceptible to the disease and that disability in college students represents a peculiar economic loss, college administrators, through facilities for the care of student health, are concerned with the inauguration of control measures among college students. The American Student Health Association has accepted the challenge and by means of a central tuberculosis control committee has set up and recommended for adoption by colleges a program of case finding. During the 2 years in which this plan has been operating many colleges have reported progress while fairly complete surveys including histories, physical examinations, tuberculin testing, and

X-ray studies of positive reactors with follow-up of suspicious cases have been reported by some. A review of the progress of this work with the preliminary findings has here been reported. Results indicate that there is a considerable variation in case incidence in colleges in different parts of the country and that there is some variation by sex and age. It appears that almost 10 times as many cases have been found in colleges where control programs are being conducted than in colleges where no methods of early identification are being used. The value of the case finding surveys and attention to contacts and to suspicious cases in follow-up is here revealed. It is hoped that more thorough programs will soon be instituted in many colleges and that the results of such studies will lead the way toward similar methods of control in young adults in our industries and in our communities.

DISCUSSION

HAROLD G. TRIMBLE, M.D.

Oakland, Calif.

IF the Student Health Services of our universities are properly to safeguard the physical welfare of the students as well as to act as the practical health educator to our future community leaders, their tuberculosis problem must be handled in the fashion of today, not from the knowledge and methods of the past.

Those of us interested in tuberculosis are indeed remiss in having failed to get over even to the general medical public our modern thought of this problem. I refer to the necessity of tuberculin tests plus X-ray of the positive reactors. This well accepted procedure has certainly not been used by medical men in general in their daily work, and only in a relatively few University

Health Services. Tuberculosis is still the disease that kills the greatest number during the productive years of life. We preach early diagnosis for curability and yet 80 per cent of our cases are far advanced when first seen, and this percentage would be higher if we left out the primary pleural effusions.

We have progressed beyond the stage of treatment of the easily recognizable disease by virtue of symptoms and positive findings on routine physical examination. A study by Sampson and Brown¹ on 1,367 consecutive admissions shows the following with reference to their five diagnostic points.

The significant part of these figures to me is that 3 out of 10 of these cases of tuberculosis sent for sanatorium

Tubercle bacilli	61.5
Râles	68.5
X-ray	99. +
Hemoptysis	33.5
Pleurisy	12.0

treatment could not be diagnosed by the use of routine physical examination alone. This fits in with our own experience, and if we considered merely early lesions the difference would be far greater.

The matter of cost—particularly of X-ray film—is probably one of the most potent forces in preventing widespread use of the tuberculin plus X-ray studies of students. Budgets are not very flexible, especially when revised upwards.

For some years we have used, to our complete satisfaction, in private work, in clinic and hospital, fluoroscopic X-ray to separate positive from negative chests. This of course greatly reduces the costs. With the Patterson B. screen and a good tube and transformer, the technic is greatly simplified. The report of Fellows² was interesting to us in amply confirming these facts from quite a different point of view. I would commend the earnest study of his presentation to you. We have taught a number of younger men to handle the fluoroscope readily for this purpose and have just completed a fluoroscopic survey of 2,000 high school seniors using a portable fluoroscope. This worked very well.

I must tell of a talk just the other day with Dr. Walter M. Dickie, who for years was Secretary of the California State Board of Health. We were leaving a meeting of our local tuberculosis association when such a study of a university group was under discussion. He pointed out the analogy of this tuberculosis problem at this time to the story of the control of typhoid. It seems that by sanitation and isolation, the typhoid rate was brought down to a low level and there

it stuck without change until real effort and true epidemiological technic was brought to bear on the problem by tracing to its source each case when possible. A further marked drop then occurred down to our present level. The analogy seems complete.

If we will look on tuberculosis today as just such an epidemiologic problem and find out definitely by using tuberculin plus X-ray just where infection and disease lie in our college student bodies, we will not only be bringing to bear on this problem the best of modern weapons, but many individuals will be personally benefitted and a fine piece of health education accomplished.

College students are of the age group where we find the disease tuberculosis appearing. For at least 4 years their physical welfare is the responsibility of the Student Health Service. The tools are ready at hand, and tuberculin tests and some form of X-ray are simple in their application.

Let me close with a brief report from Dr. H. D. Lees, University of Pennsylvania. There the plan of X-raying all freshmen was found inadequate after several years' experience. All students are now examined routinely with the tuberculin test plus the X-ray. Of 15 cases examined because they applied for relief of symptoms, 12 were advanced cases of tuberculosis and obliged to leave school. Of 17 cases picked up by the routine tuberculin X-ray plan, all were symptomless and only 1 was dismissed from school.

Whether it be from the strictly scientific standpoint, from the economic or humanitarian, these facts alone would point to the necessity of incorporating these procedures in the routine of each Student Health Service.

An Experimental Critique of the Allen Method of Evaluating the Bactericidal Action of Antiseptics

KEITH H. LEWIS AND LEO F. RETTGER

Department of Bacteriology, Yale University, New Haven, Conn.

THE status of bacteriological methods for determining the relative values of germicidal agents has been so far advanced during the past half century that many have come to feel that the ultimate solution of the problem lies, not in the field of bacteriology but, as Topley and Wilson have said, "in the domain of the physical chemist." This attitude is reflected in the relative scarcity in recent bacteriological literature of attempts to bring laboratory procedures into closer harmony with conditions encountered in the practical use of antiseptics and disinfectants. For even the phenol coefficient method advocated and employed by the U. S. Food and Drug Administration (Ruehle and Brewer, 1931) with all its good qualities of quantitative precision and controlled factors cannot pretend to approximate ordinary conditions of bacterial contamination and infection.

Among the few reports along this line which have appeared is the work of Allen (1929) and of Allen and Wright (1931). In the first of these papers a method is described in which the relative values of antiseptics are determined by the rapidity with which they appear to kill organisms on the surface of slant agar cultures. Results obtained by this method are given for tests made in duplicate with 21 antiseptics against 4 widely different

species of bacteria. The second paper is largely in the nature of a discussion of methods of determining the value of antiseptics; and it includes a brief review of Allen's original method, with certain modifications which are aimed at more accurate standardization of the technic. Unfortunately, no experimental data are included in this second paper to show the worth of these modifications.

On the ground that the surface of an agar slant culture more nearly resembles contaminated or infected tissue than does the liquid suspension used with the Food and Drug Administration method, Allen and Wright contend that data obtained by their procedure are of greater practical significance. Even the admission of Allen that his "method of determining the bactericidal values of antiseptics is open to criticism" has not called forth any published statement to support or refute the claims made for it. The aim of the present work was to examine this technic experimentally, with a view to determining what, if any, promise it holds as a practical method.

METHODS

The procedure which was first reported by Allen will be referred to in this paper as "Allen's Original Method," and the modified technic de-

scribed by Allen and Wright as "Allen's Modified Method." Parts of each paper are quoted.

Allen's Original Method—"The organisms used were a freshly isolated strain of *Staphylococcus aureus*, a similar strain of *Bacillus pyocyaneus*, and laboratory stock cultures of *Bacillus subtilis* and *Bacillus typhosus*. Preliminary to the actual experimental work, each culture was transplanted for 5 successive days on agar slants. Immediately preceding experimentation, 2 fresh transplants were made from the 5th daily culture to agar slants. These were labeled B and X, while the parent culture was labeled A. Culture X served as a control of growth; A was a 24 hour old culture, while B was a freshly inoculated slant. Twenty-one such groups were made up, using each of the 4 organisms employed.

"To each of the 21 A and B groups of the 4 cultures, a different antiseptic was added in such quantity that when the culture tube was held in the vertical position, the slant surface was entirely covered by the antiseptic solution, insuring continuous contact of the agar slant surface with its culture and the antiseptic. At intervals of 15, 30, 60, and 180 minutes, transplants were made from the A and B tubes to fresh agar slants A', A'', and B', B'', etc. A previously flamed platinum loop was inserted into the supernatant antiseptic fluid, down to the agar surface, where the loop was drawn across the agar slant surface with its bacterial covering. This loopful of suspension was withdrawn through the antiseptic fluid above and streaked on a fresh agar slant. These tubes plus the original were incubated at 37° C. for 24 hours and then observed. . . . The agar was the usual meat infusion agar titrated to a pH of 7.4."

Allen's Modified Method—"Organisms of known virility and resistance to phenol according to the classification of Reddish are used. They are transplanted for 3 successive days on agar slants of the following composition: Armour's peptone, 10 gm.; Liebig's beef extract, 5 gm.; salt, 5 gm.; agar, 15 gm.; distilled water, 1,000 c.c., adjusted to a pH of 6.8. Five c.c. of the agar is placed in each of the usual 5/8" by 5 7/8" lipped test tubes and autoclaved at 20 lb. pressure for 1/2 hour. Immediately on removal from the sterilizer the tubes are set at an angle of about 15° to the horizon to insure as nearly as possible even and equal slant surfaces, and also to prevent the formation of the undesirable water of condensation which re-

sults from the usual remelting and recooling method of preparing the slants.

"From the 3rd successive culture a fresh sub-culture (known as A) of each organism to be used, is made as follows: With a straight nichrome needle, a smear, or at least three streaks, are made on a fresh agar slant (A). This is incubated at 37.5° C. for 24 hours. At the expiration of this time, 10 c.c. of the antiseptic to be tested is added to the culture (A). This should be adequate to cover the slant completely when in an upright position. The antiseptic is added at a temperature of 37.5° C. Thenceforth the cultures are maintained at the same temperature by means of a water bath. At intervals of 5, 10, 15, 30, and 60 minutes, transplants from the cultures (A) are made on fresh agar slants (B) or Petri dishes (medium as previously described) as follows: With a straight nichrome needle a transplant is removed from the surface of the agar slant (A) and at least 3 streaks made on the fresh agar (B). This (B) is incubated at 37.5° C. for 48 hours and then read."

"Subcultures (C) are made from all transplants (B) in which there is doubt as to the presence of growth of the organisms."

Present Methods—With the few limitations noted below, the general methods employed in this work are those already quoted. Experimental modifications will be mentioned in discussing the data.

Staphylococcus aureus (Reddish strain), *Pseudomonas aeruginosa* (N. Y. U. strain) and *Eberthella typhi* (Hopkins strain) were used throughout as the test organisms. When tested according to the U. S. Food and Drug Administration method of determining Phenol Coefficients at 20° C. they resisted phenol concentrations of 1:70, 1:80 and 1:90, respectively, for 5, but not for 10 minutes. *Bacillus subtilis* was not employed, because it is a spore-forming organism and, therefore, offers serious difficulties in experiments of this kind.

Ten of the 21 antiseptics reported by Allen in 1929 were used. They are listed in Table I, 6 under their customary names, and 4 by numbers.

It was impossible, of course, to know

TABLE I

<i>Antiseptics</i>	<i>Concentration</i>
Phenol	1:1000, 1:100, 1:50
Ethyl alcohol	1:1.25 (80 per cent)
Mercuric chloride	1:1000
Dichloramine T	1:20 (soluble portion)
Hydrogen peroxide	Market product; full strength
Tincture of iodine	U. S. P., full strength
Solution No. 7	} Well known trade products
Solution No. 8	
Solution No. 9	
Solution No. 10	

the composition of the "usual meat infusion agar" used in Allen's Original Method. We employed the standard beef infusion agar, which contained the fresh extract of 500 gm. of lean beef per 1,000 c.c. medium, 5 gm. of Bacto-peptone (0.5 per cent), 5 gm. of sodium chloride (0.5 per cent), and 15 gm. of Difco-agar (1.5 per cent). The pH was adjusted to 7.4-7.6 before the addition of the agar.

In all experiments other than those dealing with Allen's Original Method the medium recommended in Allen's Modified Method was employed.

EXPERIMENTAL

TESTS MADE ACCORDING TO ALLEN'S ORIGINAL AND MODIFIED METHODS

In order to determine what degree of accuracy may be expected from both the original and the modified method of Allen, three series of tests were conducted using both of these procedures. The technics described by Allen were adhered to. Where the published directions lacked completeness, the points in question were elucidated in a personal communication from Dr. Allen. Perhaps it should also be emphasized here that these experiments had, as their real purpose, evaluation of the methods, rather than of antiseptics.

Because the data collected are of such volume as to forbid publication, even in tabulated form, the results are presented here in more or less condensed, commentary form.

1. Considering each culture tube subjected to medication as the unit

test, it was found that 20, or about 9 per cent, of the 216 tests made according to the original method showed irregularities or skips (negative sub-cultures followed by positive sub-cultures at a later time interval) within themselves. Eight skips (8 per cent) occurred in the 97 tests made according to the modified method. While these numbers are not in themselves of sufficient magnitude to constitute a very serious fault, a study of specific instances shows that the nature of these irregularities is particularly annoying and undesirable. For example, the 24-hour culture of *Ps. aeruginosa* exposed to phenol (1:100) in a test made according to the original method, showed no growth in transplants made at intervals of 30 and 60 minutes of exposure, while after 15 and 180 minutes growth did occur. An illustration of a similar situation occurring in tests made according to the modified method is to be seen in the case of a 24 hour old culture of *Staph. aureus* which was subjected to ethyl alcohol (1:1.25). Transplants made at intervals of 5, 10, 15, and 30 minutes after medication showed no growth, but at the end of 60 minutes the organism was recovered. In these cases, as with all questionable results, further sub-cultures were made, to determine the presence or absence of the original test organism. Almost any one of the other tests in which skips occurred could be used to illustrate this defect which, as will be shown later, is largely inherent in the method.

2. A comparison of the three series of tests with each antiseptic made according to both technics showed that complete agreement of results was obtained only when no growth occurred in sub-cultures at any of the four time intervals, or when it occurred in all. In other words, when complete killing or marked reduction in the number of living cells took place between the time

of the first and last transfers, the results varied so widely that it was impossible to assign any definite values to the antiseptics. Obviously, this type of discrepancy imposes serious limitations on the test; for, if it is not reproducible little can be gained by its use. The fact that the series of tests with the Original Method were carried out at room temperature (22–25° C.) in accordance with Allen's directions (personal communication) has perhaps contributed to these variations. However, it should be stated that tests with the modified method in which the temperature was held constant were not free from this error.

3. The data obtained by us are by no means in accord with those presented by Allen for supposedly similar tests. While the much overworked "personal equation" may be a factor, it is impossible to explain all of the differences between his and our own results on this basis. In our work, 0.1 per cent phenol showed no killing action on any of the test organisms when they were exposed for 3 hours at room temperature, and on one occasion viable organisms were recovered even after 24 hours of exposure. Allen reported, however, one set of data in which he did not recover viable *Staph. aureus* or *Ps. aeruginosa* after exposure of more than 1 hour, and *E. typhi* after an interval longer than 30 minutes, when 24 hour old cultures of each were exposed to this concentration of phenol. Granting that his results were obtained with different strains of bacteria from those used here, it scarcely seems compatible with common knowledge of the properties of these organisms to assume that any authentic strains should show such extreme susceptibility. Since no certain explanation presents itself, this point must be accepted simply as further evidence of the unreliability of the method.

Although Allen's Modified Method

appears somewhat more satisfactory than his Original Method, it too exhibits the same fundamental defects of irregularity and lack of reproducibility. Consequently, the criticism presented above may be considered to apply equally to both technics.

A CONCEALED FACTOR RESPONSIBLE FOR SOME OF THE DISCREPANCIES

Having tried unsuccessfully to show that the lack of uniformity in results could be attributed to variations in temperature, failure to distinguish between growth and debris carried over from medicated cultures to sub-cultures, mechanical variations in making transfers, and a number of other possible factors, it was thought that perhaps the medicated agar slant cultures themselves were responsible for the lack of uniformity.

To test this possibility duplicate infusion agar slope cultures evenly covered with the 3 test organisms were subjected to 2 per cent phenol at 20° C. Transfers were made according to Allen's Original Method, except that at each time interval 2 sub-cultures were inoculated from each medicated culture instead of 1. The inoculum for the first was taken from the upper half, but not the extreme tip, of the slant, and for the 2nd from the lower half near the base of the sloped surface. When these pairs of sub-cultures were observed after 24 hours incubation at 37° C., and rechecked after a 2nd day of incubation, the results recorded in Table II were obtained. When sub-cultures were inoculated with material taken from the upper parts of the medicated slopes of *Staph. aureus*, *Ps. aeruginosa* and *E. typhi*, the only transfers in which growth occurred were those made from 24 hour cultures of *Staph. aureus* at the first time interval (15 min.). In sharp contrast to these results, the transfers made from the lower portions of the same medi-

cated 24 hour old cultures showed growth even after 3 hours of exposure. The fact that the freshly inoculated slants showed a similar trend would seem to indicate that probably some external physical factor, rather than any actual difference in resistance of the organisms, is responsible for these results.

For the sake of brevity, only the limited data presented above can be included here, but care was taken to extend the investigation of this point to repeated tests with Allen's Original Method and Allen's Modified Method, and with the use of 8 antiseptics, in addition to phenol. The more or less

general agreement of these experiments in showing a marked difference in length of time required to kill the organisms on the upper half of an agar slant as compared with that required to destroy those at the base of the same slant can leave little doubt about this physical factor being of general importance in interpreting the faulty results obtained by Allen's technic. Since his directions make no restrictions as to what portion of the slant the inoculum should be taken from, the operator is at liberty to pick indiscriminately from the upper or lower portions. If by choice or by chance he takes the inoculum from the lower part at the first and last time intervals, and from the upper portion at the end of

the intermediate periods, he will be very apt to observe growth only in the first and last sub-cultures. Should he repeat the same test, it is quite probable that he would not transfer from the same areas at the same time intervals, and would thereby get a set of results which differ from the first set. Also, a technician knowing this trick could, within limits, vary the results to suit his fancy.

While the above comments do not entirely explain the difficulties encountered, the point stressed appears to us to constitute a sufficiently serious objection to Allen's technics to lay data obtained with them open to serious question.

A FURTHER MODIFICATION OF ALLEN'S METHOD

The central idea upon which Allen's method is based is that the bactericidal action of antiseptics upon organisms matted on the surface of an agar medium more closely resembles the ability of these agents to destroy bacteria in contact with the animal body than does the action exerted against the naked suspensions of organisms used in the standard Food and Drug Administration method. Although an agar gel can scarcely be considered as an adequate substitute for living tissue, this effort is certainly a move in the right direction.

Having demonstrated that the procedures recommended by Allen do not give satisfactory results, an attempt was made to incorporate the agar culture idea into a test sufficiently simple and accurate to make it practical. To this end a variety of experimental modifications was employed. Because most of these were found to be without any real merit, they are not included in this report. However, from the experience gained in these investigations, it was possible to evolve a modification which shows some promise

and appears to be no more faulty than some of the present accepted technics. A description of this procedure is given here.

Tubes containing 5 c.c. of the agar recommended in Allen's Modified Method are prepared and, after sterilization, are allowed to solidify in an upright position so that the flat surface of the medium is at right angles to the walls of the tube. These tubes are inoculated with 0.1 c.c. of a 24 hour-old broth culture of the desired test organism, which had been transferred serially on the 5 preceding days through broth of the same composition as the agar medium before the agar is added. The inoculum must be spread evenly over the surface of the medium. The agar tubes are incubated for 24 hours at 37.5° C. Ten c.c. of the germicidal agent to be tested are then introduced into the culture tubes by allowing the liquid to run down the side of the tube in such a way as not to disturb the bacterial growth on the surface of the agar. The medicated cultures are held in a water bath at the desired constant temperature (37.5° C., in our tests). At given periods of time (usually 5 minute intervals) transfers are made to 10 c.c. of sterile broth by means of a 4 mm. nichrome loop which is so bent that a 90° angle is formed at the juncture of the loop and the straight wire shaft. The flamed and cooled loop is passed through the germicidal solution to the surface of the agar without penetrating the medium. Sufficient bacterial growth to be easily visible is gently scraped from the surface onto the needle, which is then carefully withdrawn and the inoculum deposited in the receiving broth. The broth tubes are incubated for 48 hours at 37.5° C., and subjected to careful observation for evidence of growth.

Table III may serve to illustrate what may be expected of this procedure.

SUMMARY

Repetition of the procedures recommended by Allen in 1929, and Allen and Wright in 1931, for evaluating antiseptics has shown that because of skips and lack of repeatability these methods are unreliable. A major portion of the faults of these technics may be attributed to the fact that organisms on the lower portion of a medicated agar slope are less readily killed than those on the upper portion.

Although the results presented here indicate that little significance may be attached to the two methods of Allen, and to his reported data, they do not necessarily imply that the principle of determining bactericidal action of substances upon organisms growing on an agar surface lacks merit. The presentation here of a further modification of the agar culture technic is based on limited observations. It does, however, appear to obviate some of the difficulties of Allen's methods.

in the way of constancy of results when the technic is carefully carried out. These data have been obtained by subjecting 6 cultures each of *Staph. aureus*, *Ps. aeruginosa* and *E. typhi* to 1:80 aqueous phenol. The 3 control tests in which no growth occurred represent sterile agar tubes subjected to phenol, while the 3 controls showing growth are cultures of *Staph. aureus* subjected to 10 c.c. of sterile water. From these results it will be seen that no skips occurred in any of the tests and that, while the killing time in each of the 6 series of tests was not identical, in no case did it vary by more than one 5 minute interval from the average.

Considerable doubt is felt as to the advisability of presenting the above modified procedure, because the work done on this phase of the problem has been quite limited. Nor is it our intention to present this procedure as a substitute for, or supplement to, the generally accepted Food and Drug Administration Method. We believe, however, that it may be of scientific interest, and that in its present or further modified form, it may be of some value in the evaluation of antiseptics under more nearly practical conditions than most methods have admitted.

Relative Toxicological Effects of Synthetic Ethanol and Grain Fermentation Ethanol in Blended Whiskies

C. W. MUEHLBERGER, PH.D.

Department of Toxicology, Northwestern University Medical School, Chicago, Ill.

SINCE the repeal of the 18th Amendment to the Constitution and the legalizing of the use of alcoholic liquors, the question of blended whiskey has again aroused interest. Prior to the advent of prohibition, the alcohol used in the preparation of blended whiskies was produced largely through the fermentation of grain-mash. Smaller amounts were produced by the fermentation of blackstrap molasses. Today, the most economical source of fermentation alcohol is probably molasses. The synthesis of ethyl alcohol from ethylene has been known to organic chemists for a long time, but this process has only quite recently been developed on a technical scale of production, utilizing the gases resulting from the "cracking" of petroleum. The ethylene from this source is combined with sulphuric acid to form ethyl sulphuric acid. This, in turn, is hydrolized with alkali to produce ethyl alcohol. This synthetic alcohol is now obtainable in large quantities in a very high degree of purity, at prices which compare quite favorably with fermentation alcohol.

These studies were undertaken to determine whether there was any detectable difference in the intoxicating or toxic properties of alcohol produced by grain fermentation and that synthesized from hydrocarbons, and,

furthermore, to compare their effects when used in blending whiskies.

TESTS OF COMPARATIVE EFFECTS OF SYNTHETIC AND FERMENTATION ALCOHOL

The samples of alcohol employed were purchased on the open market and were found to correspond to the requirements of the United States Pharmacopoeia. The fermentation alcohol was stated by the manufacturer to have been prepared from grain. It contained 94.94 per cent ethyl alcohol and 5.06 per cent water, by volume. The synthetic product contained 95 per cent ethyl alcohol and 5 per cent water, by volume. When the U.S.P. tests were applied, both specimens gave negative reactions for fusel oil constituents, acetone, methanol, and aldehyde. It can be stated from the chemical tests that these were both samples of the constant boiling mixture of ethanol and water, which constitutes the common 95 per cent alcohol employed in pharmacy.

Animal experiments on alcohol from these two sources have been conducted in other laboratories and will be reported elsewhere. The tests reported herein were made entirely upon humans. Fifteen male subjects were employed. They ranged from 22 to 51 years of age. Of these, 6 were medical students,

4 were engaged in light labor, and 5 in heavy labor. They were classified on the basis of previous experience with intoxicating liquors, as (1) abstainers, (2) moderate drinkers, and (3) heavy drinkers. Subjects were required to abstain from all alcoholic beverages during the 48 hours preceding the test, and to report early in the morning without having eaten breakfast.

The dose of alcohol was gauged according to the weight of the subject and the reported previous experience with alcohol. Abstainers were given 0.5 c.c. absolute alcohol per kg. body weight, moderate drinkers received 1.0 c.c. per kg., and heavy drinkers received 1.5 c.c. per kg. In each case, the alcohol was diluted to 10 per cent strength with cool water. The subject was required to drink one-tenth of this diluted dose during each 3 minutes over a 30 minute interval.

Two tests were conducted upon each subject—one employing diluted fermentation alcohol and the other using synthetic alcohol. The bladder was emptied at the start of the experiment to furnish a control specimen of urine. Urine specimens were collected at 45, 90, 120, 180, and 240 minutes after completely drinking the alcohol dose. Subjective symptoms, as well as objective observations of alcoholic intoxication or any of the accompanying complicating factors such as nausea, headache, etc., were noted during the period following the drinking.

On the doses employed, the subjects reached varying stages of intoxication, ranging from a feeling of fullness in the head to a drunken stupor. The peak of the objective response, as well as the maximum concentration of alcohol in the urine, was reached at about 45 minutes after completion of the drinking. The average maximum concentrations of alcohol of the urine were 0.9 mg. per c.c. for the group of abstainers, 1.25 mg. per c.c. for the group

of moderate drinkers, and 1.65 mg. per c.c. for the group of heavy drinkers. In duplicate experiments, no real difference could be observed between the response to ethanol from the two sources (grain fermentation and synthetic).

EXPERIMENTS ON THE EFFECTS OF 4
YEAR OLD KENTUCKY BOURBON
WHISKY BLENDED WITH 50
PER CENT ALCOHOL

Specimens of Kentucky Bourbon whisky (aged 4 years) were blended by expert blenders using in one instance 50 per cent grain fermentation alcohol and in the other instance synthetic alcohol. The blended products were adjusted to a final alcohol content at 50 per cent by volume (100 proof). So far as fusel oil content, aldehydes, esters, and acidity were concerned, the content of both blended whiskies were much lower than the straight bourbon whiskey which was used. The analyses of the two blended whiskies were essentially the same.

Employing the same 15 human subjects used in the alcohol tests, similar experiments were conducted using these two blended whiskies. In calculating the dose for each individual subject, the amount of whiskey necessary to give a maximum urine concentration of 1.5 mg. alcohol per c.c. was estimated. In this way an attempt was made to rule out individual susceptibility to alcohol and to make all the subjects equally intoxicated. Based upon previous experience in the alcohol tests, this result was fairly well approximated. The various subjects all became quite intoxicated, although they varied materially in the manner in which this intoxication became manifest. Some became drowsy and fell asleep; others became sullen and morose; others were emotionally excited with fits of hilarity, singing, weeping or combativeness. Observations were made to note any differences between the two whisky

blends in each of the subjects—not only with respect to the acute effects but also for any material differences in the chronic effects ("hangover") such as headache, nausea, etc. So far as could be determined, the effects of the two blended whiskies were identical.

SUMMARY

The effects of drinking diluted ethyl alcohol from two sources, (1) grain fermentation, and (2) synthesis from ethylene, have been studied in 15

human subjects. Alcohol from these two sources blended with 50 per cent of 4 year old Kentucky Bourbon whiskey to give 100 proof blends, have been studied in same series of subjects. No difference in intoxicating effect nor in immediate after-effects ("hangover") could be noted in the effects of the alcohols nor in the whisky blends prepared from them. In their effect upon the human, synthetic ethyl alcohol is identical with ethyl alcohol produced from the fermentation of grain.

What Is Public Health?

IS not public health merely a matter of water supplies, ventilation, sewage, clinics, drains, street cleaning, garbage, infectious diseases, public health nurses, flies, dirt, slums, and serums? True it is that these items are all in it. But they no more constitute public health than mere paint, canvas, and brushes constitute art; or mere iron ore and smelters constitute architecture; or rods, lines, and nets constitute the fishing industry; or axes and wire rope constitute lumbering; or schoolhouses and textbooks constitute education. All these items are merely the tools of the arts. The tools of an art are essential to the art; but they do not constitute the art. Art is the result achieved; it is that object toward which tools merely perform the shaping of the path. . . .

That public health originated in the attempt to relieve crude physical suffering and especially to achieve this only by preventing disease, does not take

from its present or future immensely greater importance. That it has reached already its present outstanding influence is proof enough of its inherent strength, a strength derived wholly from its truth—that is, its correspondence with, not things just dreamed about, but things that are—not with just some things in the universe but with all things. . . .

The common objective of medicine and of public health is the reduction of human misery due to disease and death. The one devoted itself to the relief and cure of those already suffering, the other to prevention. Since neither fully succeeds, each must continue to supplement the other. Each in its own field has made enormous advances from each its own angle. Coöperation is increasing as each—medicine and public health—understands the other's problems better.—H. W. Hill, M.D., *Weekly Bull.*, Albany, N. Y., Aug. 8, 1935.

The Aims of School Health Service*

DON W. GUDAKUNST, M.D., F.A.P.H.A.

Director of School Health Service, Detroit Department of Health, Detroit, Mich.

THE aim of a health service in school is obviously to make for a healthier group of children. The effort, which has been carried on through the device of doing things for children, has not been sufficiently successful. It has not been as successful as the magnitude of expenditure of thought, time and money would warrant. The traditional procedure calls for the assumption of great responsibility on the part of the school staff for the health practices of the children. The school has assumed responsibility for the control of communicable diseases, for the detection and correction of physical defects of the children. When there has been danger of diphtheria or smallpox the school vaccinated and immunized the children. The cases of communicable diseases occurring in the group have been detected, diagnosed and excluded by the school staff of teachers, nurses and physicians. Physical defects have been detected and, at times and under certain conditions, corrective work has been carried out, or at least started.

The question has now been raised as to the necessity and the advisability of carrying on the same procedures year after year in the same manner. Today in most places the same kinds and numbers of physical defects are found by the same kind of physical examinations as thirty years ago. Studies made in New York, Detroit and else-

where show that only about 2 per cent of the serious physical defects discovered by the medical examiners in school are brought to correction within the year, in spite of the abundance of clinical medical services in these communities. There are 80 to 90 per cent of school children needing dental care, in spite of all the school dental clinics that have been operated. Each year in many schools it is necessary to vaccinate and immunize against diphtheria the same percentage of children as in the past in order to bring the protection level up only to a point where the health authorities hope that there will not be an epidemic, or that there will not be deaths from these diseases.

These questions are being asked not for the first time, but more insistently than ever before. An answer is more important in these days of readjustment than in the days of expansion.

A child presenting himself at school with an uncared for physical defect, or without the common, accepted, protective immunizations represents not what was once thought, but very likely an entirely different problem. The question is not one of a particular child being neglected. It is not a problem for which an answer is secured by having a physical defect corrected or immunization done. It is not as simple as that—for if it were it is only reasonable to assume that there would, at least in certain parts of the country, have been some signs of a permanent solution to the problem. Defects have

* To be read at the meeting of the American Association of School Physicians in Milwaukee, Wis., October 9, 1935.

been corrected—and yet our problem is as great as ever. We cannot measure the success of any school health service program by the number of defects corrected or the number of children immunized by the school. These things rather measure the failures of the community health program. Why should any parent or any community allow such conditions to go on year after year? Why should parents wait until the most susceptible age period for diphtheria has passed before administering toxoid? Why should a health department allow a full fifth of its entire population and its most susceptible age group (the preschool group) to go unvaccinated? Is it good medical practice to allow such physical conditions as progressive myopia, congenital syphilis, rheumatic heart lesions, focal infections of teeth and tonsils, and similar other progressive conditions to go on year after year without active and continuous medical treatment? Yet are not these the very conditions that we find in our schools? If the traditional school health service has not directly contributed to this state it has at least been of little avail in correcting it.

There is another thought that serves as a challenge to school physicians. Let us consider the group that has left our schools and attempt to analyze its thinking in respect to medical services. The high school student has for 12 or more years been given certain medical services. In most places, rural and urban, he was vaccinated by the school doctor, he was given toxin-antitoxin or toxoid, Schick tested, given a Dick test or Dick toxin. Each year, or at least every 3 years, in the more progressive schools he was given a physical examination, and recommendations were made to him and his family as to what should be done about the defects found. He was protected against exposure to communicable diseases

through the action of the school staff. In other words for more than a decade of life the school child is taken as a ward of the state in respect to medical care. He is taught to turn to and depend upon the school teacher, nurse, and physician for all his essential medical advice and even service. Not only is he taught to depend upon this staff for the things that need to be done, but he is taught to lean upon them for knowledge and information as to whether anything needs to be done. All health factors of the school child, both those that are a credit to the child and those that are considered detrimental, are motivated by, detected and appraised by the school. The child has little opportunity to play anything but a most passive part. As a result of this sort of education we cannot expect to find a high school graduate well trained in that phase of good citizenship that has to do with the preservation of health. Upon leaving our schools there is no one upon whom he can lean. There is no longer a school doctor and nurse to tell him that he is right or wrong. During these years in schools there has been little or no attempt to point the way he should go after leaving. This point is not lost sight of in the more traditional parts of the school curriculum. Health education when carried out under that name attempts to do the thing that is desired, but the service side of the program almost always directly violates the teachings of the educators and children are not taught how to care for themselves. It has never been demonstrated that there is any educational carry-over value to doing a thing for a child. He must learn how to do it himself. This is accepted by all educators. Yet we have attempted the educationally impossible in health. We have tried to teach our school children to be good citizens, to care for themselves, to help preserve the health of

the nation, and the race, through the process of having all the things that have been mentioned done for him. We have done our best to teach the public the very opposite from that which seems to be most desired—continuous medical services intelligently sought and capably administered.

When a child enters school with a physical defect which has not been, but should be, corrected there is a real problem presented to the school health authorities. Here is a challenge to the educational forces of the community. This child represents a problem in either individual or community health education, or possibly both. The mere detection or correction of the defect does not alter the fundamental condition that allowed for the persistence of an uncorrected defect. The problem, if individual, may be one of education of that child's family. It is usually found that the parents are lacking in appreciation of the need of medical care, or having this they are lacking in the knowledge of how to secure the care that they know to be needed for the child. Either one or both of these may be present—and either one or both should receive the attention of the school health authorities. The correction of these lacks of knowledge automatically takes care of the correction of the defect in the child. But the effects are more far-reaching than this immediate objective. Having learned the need, the advantages, and the method of securing medical care for one member of the family for a particular reason it is not too much to expect this lesson will have a carry-over value and in the future the health of the entire family unit will be better cared for in other respects.

At times the fault does not lie with the individual family. It must be admitted that under certain conditions the family may have a proper appreciation of a continuous medical service but be

totally unable to secure such care for purely financial reasons. Then the fault is one of community health education. Those school health authorities who busy themselves only with the particular child, and his isolated defect, follow a very short-sighted policy. They miss the bigger opportunity. Every effort must be used to awaken the civic leaders to their responsibility. The school is an admirable situation to elicit and direct public action to care for the well-being of the entire population. The civic and medical leaders should have pointed out to them the fact that there are not sufficient medical facilities available for all classes of people. Under proper stimulation and guidance the community then will go a long way in correcting this fault of community health education.

Here then, we have our problem. The school health service program of the past has not been an effective device for the education of either the particular child or of the community as a whole. Year after year the school has been presented with the same old problems and has had new ones added as time went on. People have not been taught to use their own initiative in securing either corrective or prophylactic medical care. They have not become acquainted with the medical facilities and practices of the present day, nor have they learned the method of using them to the best advantage.

This problem is one of education. It calls not so much for new forces and new efforts but rather for a re-direction of the old efforts and a new thinking. The examination of the school child no longer needs to be a fact-finding device. The experiences of the past third of a century of school medical work afford sufficient evidence to prognosticate the percentages of defects in almost any age group. It is better that the examination be used as a personal demonstration to the child's own par-

ents of the need of medical care. The school physician, having demonstrated the need of care, can then point out to the parents at the same time the means of obtaining that care. This means will vary with the individual child and the particular community and its facilities.

Further than this, when the health forces of the community fully appreciate the health problems of the school child as they exist today and when the community learns to meet the problems, then there will be need for less and not more medical work in schools. When the parents of school children have learned the advantages and means of giving continuous medical supervision to their children during the periods of infancy and preschool life, when children enter school protected against communicable diseases, with defects corrected or prevented, with health habits properly directed, then the school physician will have a different rôle to play—that of the educator alone.

But the education of the parents is not sufficient. The medical forces of the community must also be stimulated. The entire blame for the appalling findings recorded by any school physician cannot be laid solely at the door of the parents. Too frequently the medical profession itself has been indifferent to the problem and has assumed that all the necessary things would be cared for when the child entered or was about to enter school. Not only must the parents be brought to the school to have a demonstration of the need for medical supervision of children's health but so, too, must the physicians. What then is more logical than to have the practising medical fraternity make the examinations, conduct the demonstrations and give the education relative to the methods of securing the indicated care. If each physician practising in a community could serve as a school phy-

sician it is only reasonable that with proper guidance and supervision he would then translate his school experiences in terms of his own practice. The schools then would serve not only the parents, but also the physicians.

In order to gain these ends and in following out these ideas Detroit during the past 12 years has radically departed from the practices of most other communities. Diphtheria immunization has been discontinued as a school problem. For 7 years none of this work has been done in school. The time, efforts and money that would otherwise be spent on this have been directed towards teaching the people to go to their personal physicians for this service at the time of life when the child is most in need. As a result no school has less than 65 per cent of the children protected before they enter the kindergarten.

No school physician serves on the health service staff for a period greater than 2 years. During this time each is given an insight into the services that the schools expect to have performed for the children long before they enter. Instead of a small staff of full-time physicians doing the necessary work, as many as possible are employed through the system of decreasing the hours each serves.

Another departure from the usual is in the matter of physical examinations before or shortly after entering school. Each school nurse and all other public health nurses carry and distribute examination blanks to all parents with whom they come in contact during the year. If the child is of school age, or shortly is to enter school, the parents are instructed to return the blank to the school. But always it is impressed upon the parents that this is a responsibility of theirs—it is they who must see to it that the child has a periodic health examination. This same examination blank is used for all grades

and all age levels. Two out of 3 of all the physicians of the city filled out such blanks during the past school year.

There has been an attempt to set up a system that will direct the attention of the child and the community away from the school in matters pertaining to health service. An effort is being made to have all possible protective services rendered during the earliest periods of life before the school age.

People are being taught to turn to their own physicians for health guidance for all age levels. School children are being guided and trained in health practices that will not of necessity end with the formal school period. The coöperation of the practising physicians in this move is obtained for it is they who actually do the work. The plan is feasible and workable, and it is giving the desired results—not only a healthier school child, but a healthier community.

On Immunisation

LASTLY, one final word on immunisation. Personally I find it difficult to believe that active immunisation of the population against every conceivable infection is the last word in prevention of infectious disease, but at the moment we must admit that so far as these personal infections are concerned, it is by far the most potent preventive we possess, and it would be foolish not to make full use of it in appropriate circumstances. Most people are prepared to give the method a fair trial if its purpose is clearly explained to them and the element of compulsion is eliminated. Apart from vaccination against smallpox, which remains the only really effective means at our disposal for combating this disease, one of the most important recent additions to our armamentarium is diphtheria prophylaxis. To anyone contemplating a trial of this method I would emphasise the importance (1) of educating

the parents and particularly the mothers as regards its advantages; (2) of enlisting the support of the local medical profession, and in this connection I would refer to the valuable report recently prepared by a committee of the British Medical Association under the chairmanship of Professor Picken, in which the whole question is carefully reviewed; and (3) of concentrating on the younger ages. The age of maximum incidence of diphtheria is six to eight years, and American experience suggests that at least thirty per cent to forty per cent of the children below this age must be immunised to ensure against a serious outbreak.—Presidential Address on Some Aspects of the Problem of the Prevention and Control of Infectious Disease, by Thomas Carnwath, D.S.O., M.B., D.Sc., D.P.H., Deputy Chief Medical Officer, Ministry of Health, *J. Roy. San. Inst.*, Sept., 1935, pp. 94–95.

WHAT SHALL WE THINK OF SOCIAL SECURITY?

NOW that the tumult and shouting in Washington has died, is it not well for us to hold at arm's length this unprecedented plan of federal aid in states and to seek for ourselves and the health enterprise a calm and detached orientation?

It is quite obvious to all those familiar with attitudes of previous sessions that something new and quite different has been present in the deliberations of this 74th Congress so far as the sentiment toward public health is concerned. Instead of the policy to reduce federal expenditures for public health to the lowest possible level there has come into the picture the President's group for the study of social security. Along with important investigations on old age and unemployment insurance there has been conducted a systematic study of the possibility of expanding local health services through a system of federal aid to states. It is a highly significant fact that this provision for more health service was admitted to be a proper part of a broad program for social security and that it passed through the various stages of congressional consideration with less objection than any other provision of the entire bill. Since the report of the President's advisers on social security there has never been any serious opposition to the plan of increasing funds to be expended through the Public Health Service and the Children's Bureau to an amount vastly greater than has ever before been allowed for these worthy purposes. From this support we may well take fresh courage.

The ample majority of both the House and the Senate in favor of the Social Security Bill leaves no room for doubt as to the real intention of Congress to provide the means and the funds for this important purpose. That the Deficiency Appropriations Bill should have been defeated by a one-man Senate filibuster does not alter the main intent of this Congress to pass these measures and to see them tried out. There is every reason to believe that these new funds will be provided promptly by the session which begins next January and that not only

the very significant old-age and unemployment schemes but the provisions for aid to states for health can be operated during the second half of this current fiscal year.

There is abroad a feeling of disappointment among health workers who have been following the fortunes of this legislation. Instead of this tendency to an easy discouragement with the miscarriage of these plans there should be on the part of the public health profession a renewed determination to be more nearly ready to use these funds when they do become actually available. It still remains to be seen whether the added responsibilities which these millions bring can be used in such a fashion as to bring credit to the profession or otherwise. If through this delay of perhaps 4 months there can be more thorough planning, more adequate study of the principles and the technic of using the money, we may well be grateful that there was that much less haste.

It seems clear that money will be allotted to states only through organized medical bodies, state, county and municipal, and such funds must be expended solely in carrying out the purposes specified in the bill and in accordance with plans prepared by the health authorities of the various states, approved by the Surgeon General of the Public Health Service. It behooves the health authorities of every state, therefore, to perfect their organizations and personnel, and to plan for the useful and economical expenditure of such money as may come from the federal government under this act.

To a very real extent the problem now becomes one of finding the human resources to match the dollars. Wherever high quality human stuff can be found with the necessary technical information we may rest assured that the money will be well spent and that the cause of public health will be advanced through this extraordinary change in federal policy. There are those in high places who have openly predicted that the funds named in the Social Security Bill are too large to be wisely spent with existing facilities and personnel. Others connected with the studies which preceded the drafting of the Bill have urged that funds in an amount twice as large could be safely appropriated for these purposes. Only time will tell which view comes closest to the fact. It is only sure that American public health is to be tested by this new program in a telling way and we may well add prayer and fasting to our earnest endeavors to make this project a resounding success.

Surely we should take a thoroughly constructive attitude toward the disappointing features of the present and make certain that we do not fall back when there is so much obligation on our shoulders to face the future with courage and determination to make of this experiment a vindication of our faith in the cause of public health.

ROYAL SANITARY INSTITUTE HEALTH CONGRESS

THE Royal Sanitary Institute Health Congress was held in July at Bournemouth, England, under the patronage of King George and the presidency of Lord Balfour of Burleigh.

The official representative of the American Public Health Association was George K. Strode, M.D., the representative in Europe of the International Health Division of the Rockefeller Foundation. In his report of the meetings Dr. Strode points out features of this Congress which resemble the meetings of our Association, indicating that on both sides of the Atlantic it seems to be a

fact that personal acquaintance and contact with other professional workers is the most valuable part in such a conference.

At the Bournemouth meetings all papers which are presented in the program for discussion are printed prior to the meetings and copies are placed in the hands of each individual in order to facilitate discussion. Usually the author of the paper presents only a brief résumé, in this way saving the time of the listeners and avoiding the monotony of long papers. There may be those on this side of the Atlantic who will agree that our British confrères have achieved a real advance in this manner.

Dr. Strode points out that in these meetings there was a simplicity and an effectiveness in the program organization which he commends to all those who have the responsibility of setting up meetings of this character. The mornings only of the 5 days of the meetings were used for formal papers and discussion and the afternoons were devoted to features of interest, to formal receptions, and other activities. The medical officers of health, the engineers, the sanitary inspectors and the health visitors each held separate meetings and to these were added meetings for groups interested in subjects comparable to our section plan, but carrying section names which indicate a diversity of interest, such as the Sections on Preventive Medicine, on Architecture, on Town Planning and Engineering, on Veterinary Hygiene, and on National Health Insurance.

Those who are interested in the development of professional standards in this country will do well to inform themselves of the way in which the Royal Sanitary Institute across the years has succeeded in raising the standards in England.

AMERICAN CHILD HEALTH ASSOCIATION

THE passing of the American Child Health Association after 26 years of varied activities removes from the scene a unique organization and punctuates an important era in the development of maternal and child hygiene. This association under its present name was formed by a merger of the American Child Hygiene Association, and the Child Health Organization of America. The former was the outgrowth of the American Association for the Study and Prevention of Infant Mortality, organized at Yale University in November, 1909, as a direct result of a conference on the Prevention of Infant Mortality held under the American Academy of Medicine. Headquarters were established in Baltimore in January, 1910. A devoted and efficient executive secretary was employed who nurtured and developed the organization until its office was transferred to Washington, D. C., in April, 1922. At that time there were almost 2,500 members including 273 affiliated societies. This marked the peak in interest and support of its membership up to that time and the most extensive services the Association was able to render its affiliated societies.

At the Washington, D. C., annual meeting, President Hoover announced formally the consolidation of this association with the Child Health Organization of America. The latter had grown up rapidly after the war under the inspiration of a group of New York people and the forceful leadership of its Director. The program concerned itself largely with health education by arousing public interest in the health of school children and encouraging systematic teaching of health in the schools with the objective of inculcating health habits. Its appeal was largely

through weighing and measuring the children, a daily routine of health habits, and attractive literature appealing to children and adults alike.

After amalgamation, the new Association transferred its headquarters to New York City, leaving a small office in Washington, D. C. An extensive program was launched with greatly expanded budgets and considerable increase in personnel. Under a departmentalized set-up its program included the development of Child Health Demonstrations, Health Education, Medical and Nursing Consultation Services, Research, a Division of Publicity and Publications, and a Division of Public Health Relations. Attention was centered on Health Education, and on Research.

There is no question that this organization exerted a beneficent influence upon the public health by sponsoring the most approved methods for the prevention of maternal and infant mortality; by urging the necessity for better birth registration; by taking an active interest in improving the milk supply, and by popularizing health education for school children. The *Transactions* of the Association are veritable handbooks of the progress in Child Hygiene. Its attractive magazine *Mother and Child*, published for 4 years, followed by the *Child Health Bulletin*, did much to arouse widespread interest in maternal and child hygiene, and to suggest ways and means of meeting local problems. Many of the measures proposed and discussed at meetings of the association have been incorporated in state and local child health work. The schools now recognize health as a major objective of education and health education as an integral part of the school program.

The question arises naturally, why should such an organization close its doors at a time when rapidly shifting socio-economic forces demand skillful guidance in holding what has proved to be sound in the old and developing what is necessary to meet the new.

Does it signify that official health organizations are now in a position to take over largely the health work initiated and sponsored by voluntary societies? Does it mean that child hygiene is now fully recognized as one of the most important phases of the public health and should be integrated with every other health function? If so the omen is propitious. It raises a challenge, however, to other national health organizations remaining in the field to meet the increasing demands of maternal and child health, in national, state, and local units.

AN INTERNATIONAL STANDARD FOR TUBERCULIN

AS early as 1924 the Health Committee of the League of Nations requested the late Professor Calmette to study the question of uniformity of tuberculin. He accepted and his results were published in 1926. The employment of the intracutaneous test in sensitized guinea pigs was recommended for the titration.

The Health Committee made arrangements for comparative tests to be carried out in a number of well known laboratories. It was found that the tuberculin used in Frankfort-on-Main, London, Paris, and Tokio were of equal strength, so that it became possible to suggest the adoption of an international standard. This proposal was made at a session of the Health Committee held in Frankfort in April, 1928. The State Serum Institute of Denmark, located in Copenhagen, was selected as a central laboratory from which the standard preparation was distributed. The National Institute of Medical Research, London, offered a certain amount of standard tuberculin for distribution. Later, a standard tuber-

culin was produced in quantity by the Copenhagen laboratory, and since that time the international standard tuberculin has been distributed from that center.

The international standard tuberculin is tested by the shock method in tuberculous guinea pigs and also by the intracutaneous test in man. The guinea pig test is the most expensive and the most unreliable, and when it is possible to use the intracutaneous test in man it is the method of preference.

Efforts are being made in various parts of the world to obtain a better preparation for the international standard. Douglas and Hartley have prepared a tuberculin using a synthetic medium. This has been titrated against the international standard preparation. In America, Long, Seibert, and Aronson have worked out several preparations, and these are still under test. The first preparation produced sensitization, and was abandoned. A more recent preparation giving better results has been made, but still further studies are under way. Whatever the preparation, in the opinion of Madsen and Holm, it should be titrated against the present international standard tuberculin.

This matter, as well as a study of the various methods of making the tuberculin tests, is interestingly treated by Dr. Th. Madsen and Dr. Johs. Holm.¹ Dr. Madsen's position as Director of the State Serum Institute and experience as Chairman of the Health Organisation of the League of Nations assures us that the statements are authoritative.

PUBLIC HEALTH EDUCATION*

What Needs To Be Told—Invaluable source material is given in "The Control of Communicable Diseases," *Public Health Reports*, U. S. Public Health Service, Washington, D. C. Aug. 9, 1935.

This is a revised edition of a report by an A.P.H.A. committee.

Among the definitions of terms is the following:

Education in personal cleanliness. This phrase is intended to include all the various means available to impress upon all members of the community, young and old, and especially when communicable disease is prevalent or during epidemics, by spoken and printed word, and by illustration and suggestion, the necessity of:

- (1) Keeping the body clean by sufficiently frequent soap and water baths.
- (2) Washing hands in soap and water after voiding bowels or bladder and always before eating.
- (3) Keeping hands and unclean articles, or articles which have been used for toilet purposes by others, away from mouth, nose, eyes, ears, and genitalia.
- (4) Avoiding the use of common or unclean eating, drinking, or toilet articles of any kind, such as towels, handkerchiefs, hair brushes, drinking cups, pipes, etc.
- (5) Avoiding close exposure of persons to spray from the nose and mouth, as in coughing, sneezing, laughing, or talking.

Following the definitions of terms—

Each disease is briefly described with regard to its clinical and laboratory recognition, the etiological agent, the source of infection, the mode of transmission, the incubation period, the period of communicability, susceptibility and immunity, and prevalence.

Following this are offered methods of control—first, those affecting the individual,

contacts, and immediate environment, and second, general and specific measures bearing upon the control or prevention of the disease in question.

Thus in condensed form the report presents the facts according to current medical knowledge and experience. It contains authoritative and approved data which may be amplified and interpreted to the public for general guidance and for explaining the policies of the health department. Of course this report should be of great value to health officers, departments of health, or legislative bodies in the formulation of rules, regulations, or sanitary codes dealing with the control of communicable diseases.

In some cases particular items are listed for public education, but most of the "general measures" call for public consideration, and many of the specific methods of control need to be interpreted to the public.

This report is to be issued in separate form as Reprint No. 1697, and may be purchased from the Superintendent of Documents, Washington, D. C., for 5 cents a copy. It should be welcomed by the editorial writers of newspapers.

"Telling The Truth"—Under this title the *Weekly Bulletin*, Oregon State Board of Health, Portland, discusses truth telling (Aug. 27, 1935) which may have application beyond the field of cancer control.

Shall we tell a patient the truth? This is a very important question to the doctors and to the laity alike. The answer is not simple but is beset with an unusual number of complications. It has been shown repeatedly that the avoidance of contracting fear of cancer by the dissemination of knowledge is to increase deliberately the chances of cure. It has been demonstrated that

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

ignorance which breeds pessimism is best dissipated by frankly spreading the facts concerning the nature, prevention, early diagnosis and treatment of cancer. It has taken a great deal of time, effort and money to educate the public concerning cancer. Its attitude toward the cancer problem has reached a point where it has more intelligence and less emotion than ever before. With an over-emotional public, cancer information might conceivably prove harmful. On the other hand, with an intelligent public much greater harm would be done by not telling the truth. A public trained to expect frankness offers a very different field for coöperative cancer control than a superstitious, ignorant, and timid public.

The European countries present direct and valid evidence on this point. Sweden in 1930 presented an outstanding development in cancer control. Patients with cancer were told of their condition as a routine procedure. The ways and means of imparting this information were naturally left in the hands of their physicians. In some cases more tact and care in giving this information was necessary than in others. Eventually, however, all patients were informed and a common status was attained. Conferences with numerous Swedish medical men yielded unanimous agreement as to the wisdom of this procedure. As a result of this program, the morale was higher in both the public and medical profession. Diagnosis was rapid and accurate. Treatments were prompt and were attended with remarkable constancy and tenacity. A happy, coöperative relationship was well established and functioned to the advantage of all concerned.

In certain other European nations, ignorance and fear abound. The contrast is eloquent and amazing. This is especially important when one stops to consider how far our own procedure in the United States falls short of the optimum. It is, of course, true, that there may be exceptional cases or peculiar situations which make it advisable that the patient be kept in ignorance. These will always be detected and will, by their very relationship to the ordinary situation, serve to accentuate the great value of frankness as a policy. The real question at issue is: "Have we matured sufficiently to face the truth and to hear discouraging facts as well as encouraging ones?" Most of us believe this level has been reached. To delay longer telling cancer patients the truth is not consistent with the educational program for the control of cancer.

Drastic Safety Education — A realization that "decent, intelligent people must be protected from the fools" (quoting *Collier's*) seems to have prompted drastic ideas in automobile accident prevention.

"—And Sudden Death," by J. C. Furnas, an article in *Reader's Digest*, Pleasantville, N. Y. Has been reprinted, distributed, and even read to offenders in a court room. Supplied at *two cents*, or \$1.50 for 100. With the imprint of Employers Mutuals, Wausau, Wis., copies supplied *free*.

An editorial in *New York World-Telegram*:

A new technique is being born in the nation's battle against the automotive speed demon. It is beginning to dawn on safety advocates that statistics on the number of killed and injured do not rake the consciousness of speedsters.

The discovery is now being made that about the only thing which feaze the reckless driver is the sight of mangled bodies and wreckage or the relentless description of individual cases and specific types of death and mutilation in automobile crashes.

The New York Police Department is working along this line in the use of large posters such as the one showing a motorist holding in his arms a child he had struck. But even that illustration is prettified out of its possible effectivity. There are no blood and no evidence of the childish pain and of the groans of death agony.

From another *World-Telegram* editorial:

We believe that a few ultra-realistic cartoons erected on boards along speedways showing not only the death and physical torture but also the disfigurement and even ruin of the car—pride and joy of the owners—would help bring down the outrageous number of motor accidents daily.

But we believe the cartoons would not be very useful if they only repeated the current type of poster showing a handsome young man holding a hit child in his arms—there is no anguish, pain, blood or destruction brought home in that picture. There must be if the roadside cartoon is to have much real effect.

"Step Off the Gas!" *Collier's*. April 6, 1935. A page editorial reviewing accident statistics gathered by the Travelers Insurance Company.

"Chicago Judge Sends Youthful Violators to Look Upon Death" reports the action of a Chicago judge in sending 20 traffic violators to the morgue and to the county hospital to see some results of reckless driving. *Public Safety*, National Safety Council, 20 N. Wacker Drive, Chicago, Ill. Aug., 1935. 10 cents.

In the *Chicago Tribune*, July 1, appeared a full page of photographs, pictures of 264 of the 451 persons killed in Cook County automobile accidents in 6 months.

Starting July 1 the 10,000 licensed cafes and liquor dispensaries in New Jersey were officially directed to display conspicuously a striking poster against driving when intoxicated.

"Cinematic Effects in Practical Films" describes a sound picture to "show that, while moderate drinking may do no harm, the excessive use of alcohol is very dangerous." There are explanations and illustrations of numerous movie devices for securing unusual and dramatic effects in safety films. *Movie Makers*, 105 W. 40th St., New York, N. Y. Sept., 1935. 25 cents.

But the fundamental difficulty is brought out under "Contradictions in Social Thought" in a book review by Harry Hansen in *New York World-Telegram*. The book is "Law and the Lawyers," by E. S. Robinson (Macmillan). Says the reviewer:

Professor Robinson does not say that we are kidding ourselves when we adopt laws that the social conscience does not want enforced, but that is what his thought amounts to. For instance, everybody knows that the death record from speeding automobiles is a disgrace to our nation, but that does not stop speeding. The law makes a certain attempt to stop speeding. People who break the laws are arrested, and "the public thus protects itself against the guilty feeling that nothing is being done."

But that does not stop injuries and deaths by automobile. The manufacturer continues to talk up high speed when he sells his cars; the authorities continue to build roads intended to make speed possible without accidents. Individuals like to believe that the accidents that happen to others will not happen to them. Psychologically, our present adjustment is purely symbolic. Professor Robinson wants the law to be realistic.

"What It Would Mean to You"—From the "Foreword" of "That Eyes May See":

Think what it would mean to you, if you had never seen a Mississippi red bird; or a waxy white magnolia bloom upon a glistening green bough; or a field of feathery cotton; or a tall and stately pine; or a sunset on the coast!

This pamphlet from Mississippi State Board of Health, Jackson, presents lists in the form of diagrams which seem to give them new interest values. "Danger Signals" is really a list of 9 warning signs to teacher or parent that a child's eyes need attention, but offered as a full-page "diagram" it looks more interesting and readable than is usually the case.

Frowning	} Danger Signals
Watery Eyes	
Fatigue After Continued Use of Eyes	
Blurred Vision	
Soreness or Redness of Eyelids	
Puffiness of Eyelids or Under the Eyes	
Drooping of Lid	
Headache, Mild or Severe	
Aching of Eyes	

Book Reviewers Talk Mental Hygiene—Again mental hygiene benefits from the published experiences of one who has been through the mill.

Doubtless "Asylum," by William Seabrook (Harcourt, Brace & Co., New York), will be formally reviewed in the *Journal*. So these paragraphs are merely to call attention to the extensive reviews the book has been receiving. Written with intelligence and sympathy these reviews have presented phases of mental hygiene and its ap-

plication to a wide reading public. The reviewing, also, as has been said of the book, is "a milestone along the arduous way of humanizing the approach to the mentally affected."

When the Report Is Mimeographed—The annual report of a county health department is before me. It is mimeographed on 6 sheets, plus a title sheet, all on the plain, commonplace mimeograph paper. A staple at the middle of the top of the sheets fastens them together.

Suggestion one: Move the staple to the upper left corner.

Suggestion two: Use a tinted mimeograph paper. See the bulletins of Health Department, Middletown, N. Y., and New Mexico Bureau of Public Health to see what results from use of color in the paper, plus a sense of design in the layout of the pages.

Where Is It Published?—Reprints from professional and popular magazines would be more valuable to possible readers and students if more fully identified.

Some medical journal reprints at least give the city of the authors. *A.M.A. Journal* reprints carry the full name and address of the Association.

But two reprints from Milbank Memorial Fund, for example, give no addresses for publisher and authors, and no obvious indication of the official status of the authors. This means extra office detail in any library where there is careful filing and cataloging.

How May They Get It?—Will the author or publisher send free a copy of a reprint? Will the health survey report be sent upon request? Are samples of this or that available to any health worker?

Or, is there a price? Will it be sent for 3 cents postage? Is the distribu-

tion limited to the one state? Is it available only to school people?

At least every editor who receives a reprint or other publication would like answers to the above and similar questions. Then the editor could be more precise in his mention of a publication. He could mention material without fear that his readers might write fruitless letters. And the editor could be sure that his readers will do their share in sending postage or a price.

Thus editor and reader both will be the happier.

Health Education in August, 1935, Journal—There was much of direct interest to the health educator in the August, 1935, issue of *American Journal of Public Health*.

The quotation from Bernard Shaw, "Experts Wrong and Genuine" (page 912) might be reread to advantage whenever we call upon "experts" to evaluate our health education activities or materials.

"The Teaching of Epidemiology by Applicatory Problems," by Munson (pages 913-919), concerns professional instruction, but the recommendation of Sherlock Holmes as collateral reading, and the readable details of a new case history plan, can be applied to both school and popular health education.

In "Sewage Contaminated Irrigation Water," by Chapman (pages 930-937), is expressed an optimistic faith in the people in connection with much intestinal disease:

This condition among us has persisted because the majority of thinking people, the sort of people who are sensitive to matters of hygiene, have not realized that it existed. I am convinced that all that is necessary to end this repellent situation is to inform the people of the facts.

"Diphtheria in Grays Harbor County, Washington," by Laue (pages 948-949), reports a rural county campaign.

"A Neglected Opportunity for the Control of Respiratory Disease," by Calver (pages 953-958), emphasizes education and public opinion touching food and drink cleanliness.

"Health Today and Tomorrow," an editorial (page 960), presents the educational campaign which is to culminate in October.

"Books and Reports" (pages 973 and 977) reviews books on phases of school health education.

"Conferences" (pages 987-988) gives dates of gatherings from which we should get material for various uses, including news in newspapers.

Radio Child Study Club — In October will open the fourth year of aid to communities in Iowa in organizing study groups. Leadership is provided by Iowa Child Welfare Research Station in coöperation with Iowa State College and Iowa State Teachers College.

Four courses are offered—one concerned with the newborn infant, one with preschool children, one with school-age children, and one with adolescents. Each course is built upon a two-year plan, twelve discussions the first year constituting the first series and twelve the succeeding year constituting the second series. Parents are encouraged to complete the two-year cycle in each course chosen to gain the fundamentals involved in intelligent guidance of children. They may register for one or more courses.

A program is broadcast for each course every two weeks through the radio stations of the University of Iowa (WSUI) and Iowa State College (WOI). The broadcasts relating to the infant and the preschool child are given on alternate Tuesdays at 2:30 P.M. over WOI and at 8:00 P.M. over WSUI. Those concerning the elementary school child and the adolescent are given on alternate Wednesdays at 2:30 P.M. over WOI and on alternate Thursdays at 8:00 P.M. over WSUI. Parents may enroll under the group or individual plan.

For the plan and materials for groups or individuals, address University of Iowa, Iowa City, or Station WOI, Ames, Iowa.

Building a School Health Library — Many requests for health information from teachers and pupils of Avon Avenue School, Newark, N. J., led the health counselor of the school to approach the librarian of the Board of Education who—

was receptive to the idea and willing to give assistance. As a preliminary step, she sent a full-time ERA worker to the school who immediately began the work of organizing books, pamphlets, posters and pictures. Since all the books fell into the category of health which made their classification identical, we marked the books alphabetically according to the author's last name. The posters, pictures, and pamphlets were filed accordingly. A card bibliography was made, headed by the topics most emphasized in the grades, sleep, rest, cleanliness, food, etc. Under these headings we compiled lists of books available in our library containing the best material on the subjects. To make matters even simpler we indicated for what reading level each book was suited. For circulation purposes we used a loose-leaf notebook which served as a record of the total collection as arranged on the shelves. One title was included on each sheet and the borrower's name was recorded on this sheet.

At present our health library consists of more than two hundred books. Among these are the most recent and useful for teachers and pupils. We keep our library up to date by the addition of new books, by subscription to current health magazines, and by soliciting various health agencies throughout the country for pamphlets, pictures, etc. The Board of Education appropriates a certain amount of money each year to each school for the purchase of books, so that we are able to secure some in this way. We try to get the pamphlets and pictures free or at very small cost. We are well on our way to the establishment of a good picture and pamphlet collection for use in the classrooms.

"Building the Health Library," by M. V. Fitzpatrick. *Public Health Nursing*, 50 W. 50th St., New York, N. Y. Sept., 1935. 35 cents. A list of books most frequently consulted by teachers and pupils will be supplied at the above address. Enclose reply postage.

A much more ambitious plan for a school of nursing is described in

"Making the Resources of the Library Available," by E. Wigmore. *American Journal of Nursing*, 50 W. 50th St., New York, N. Y. Aug., 1935. 35 cents.

There is a decimal classification, discussion of cataloging, filing method, etc. Regarding the section on health education, the article says:

The making available of health education materials to the student nurse is a technic that should be taken seriously by all school libraries. . . .

Not only the school but the school library must take cognizance of this enlarged responsibility and assemble for the student nurse's information and use representative health education materials, those tools of the health educator.

Bequests for Public Health—The recent reminders that the A.P.H.A. might well be remembered in the making of wills stimulate the thought that public health in general should share more largely in bequests for the public good.

Men and women are making wills notwithstanding the current economic disturbances. Public health agencies must exert themselves now to be remembered later.

Some of the steps to be taken are outlined in a memorandum entitled "Bequests and Trusts," supplied by Social Work Publicity Council, 130 East 22d St., New York, N. Y. 10 cents.

A Pathometer for Health Administrators—To put the leading infectious diseases "on the spot" day by day New York uses a simple device.

In the pathometer here described we have a simple and very useful device for keeping an up-to-date record of the various diseases ordinarily reported to the health authorities. It consists, essentially, of a large framed cardboard showing the ten or twelve major infectious diseases in a manner illustrated by the accompanying graph. The space comparable to the tube of a thermometer

is cut out, and behind this is a piece of tape, part white, part colored, so fixed by rollers above and below that it can be moved up and down. At the beginning of each month the tape is so adjusted that the seam between the upper white portion and the lower colored portion is at zero. Each day, as cases of the disease are reported, the tape is rolled, so that the colored portion indicates the total number of cases reported during the month up to that time.

From the experience of the past five or ten years, depending upon circumstances, one calculates the average case expectancy for the particular month, and this expectancy is indicated by means of a small cardboard tab fastened as shown in the illustration. In measles it is well to calculate an expectancy for "measles years" and "non-measles years," for the figures often vary enormously.

In the headquarters of the New York City Department of Health, one of these pathometers is kept constantly up to date in the Bureau of Preventable Diseases; another in the office of the Commissioner of Health. The latter, therefore, is at all times in touch with the prevalence of the reportable diseases in the city.

Naturally, this is only one of the devices used to keep in touch with the situation, for in addition to this, pin maps to show the geographic distribution of the diseases, as well as other graphic records are also utilized. The pathometer has not been patented and is here described in the hope that the device will be of service to other health administrators.

—In *Quarterly Bulletin*, Department of Health, New York, N. Y. No. 3, 1935.

If you lack the desire for home construction, and do have the money for a purchase, a manufactured device will be supplied by Educational Exhibition Co., Custom House St., Providence, R. I.

Pan America Resolves—The Ninth Pan American Sanitary Conference, reported in *Public Health Reports*, Washington, D. C. (Aug. 30, 1935), resolved that

the principles of hygiene should be taught in public schools and other institutions of learning.

The Pan American Conference also recommended educational work in schools as a means of combating alcoholism.

Dramatized Radio Programs—"Your health, ladies and gentlemen" will introduce the new radio program of the American Medical Association. Beginning October 1, 1935, it will be offered over the Blue network of N.B.C. A list of the 28 stations will be supplied upon request to the A.M.A.

For every Tuesday, 5 P.M., E.S.T., a new type of program, in vivid dramatic form with incidental music, is being developed, showing medical emergencies and how they are met. The hero, the doctor who is available day and night for the protection and promotion of your health, is the real sponsor of this series of practical and entertaining health broadcasts.

Dental Health Education in Iowa—The Iowa Dental Education Plan has an 8-year history. It is conducted by the Bureau of Dental Hygiene, University of Iowa, Iowa City. The Bureau provides classroom supplies; teaching helps through the school year; visual material; school and community service. For a description of the plan and the materials send 5 cents to the Bureau for "Bulletin No. 361."

Free Health News Service—"What About the Health of Men Over Forty?," by Dr. John L. Rice, and "Back to School Go Children Next Month: Here's What Parents Should Do About it," by Dr. Allen G. Ireland, each a series of 10 to 12 brief news releases, are the latest from Health News Service, 22 E. 40th St., New York, N. Y. This is the "news feature syndicate organized to disseminate scientific knowledge of public health throughout the United States," furnished by milk interests, but free from trade propaganda.

Hygeia, September, 1935—Topics for talks and articles, quotable ma-

terial, reference and background material for popular use, are found in *Hygeia*, 535 N. Dearborn St., Chicago, Ill. Here are selected articles from the September, 1935, issue:

School health policies. School report cards (their significance). Osler the man. Curious stories about health (a new series). What's behind the label? (cases of dermatitis from toilet preparations). Obesity, the open door to diabetes. Diphtheria—the big bad wolf (diphtheria no longer invincible). What should your child dance? Hygiene of the eye. The mystery of the red-faced man (medical detecting). Primitive medicine (among the Zulus). Powders and syrups for food drinks. The art of the toothbrush. Paul Ehrlich (another pioneer scientist). How to spoil a child (coddling the convalescent). Is basketball a girls' game? How bacteria grow. New books on health. Questions and answers.

In "School and Health":

The use of textbooks (in teaching health). Health teaching in September. Teaching health through a study of communicable disease. The "why" of some health habits (how children may be taught reasons for health habits). The study of foods begins in the (school) cafeteria.

DATES AHEAD

Oct. 6–12. Fire Prevention Week. Program material from Nat'l Board of Fire Underwriters, 85 John St., New York, N. Y.

"Empire Health Week" in Jamaica has been changed from Oct. 6–12 to Oct. 20–26, 1935.

FOR EDUCATION AND REFERENCE

A group of reprints on medical aspects of dysentery are supplied by Dr. Joseph Felsen, 667 Madison Ave., New York, N. Y.

A new poster calling attention to public health nursing is offered by National Organization for Public Health Nursing, 50 W. 50th St., New York, N. Y. Samples: on paper, 20 cents; cardboard, easel back, 30 cents. Low quantity rates. Space for local agency imprint.

The last contribution of the National Tuberculosis Association to the 1935 Early Diagnosis Campaign is a collection of "Quotations" assembled from "nationally known authorities on tuberculosis." The new feature is the comment on each quotation which interprets or amplifies the quotation for popular use.

"An Organized Community Health Education Program," by Savel Zimand. Reprint. *Milbank Memorial Fund Quarterly*, 40 Wall St., New York, N. Y. A valuable descriptive outline.

"Children's Bureau and Other Publications Relating to Children." Supt. of Documents, Washington, D. C. *Free*. If desired ask also that future revised editions be mailed to you.

"On Health's Highway: Progress in Relation to Cancer Control." New York City Cancer Committee, 150 E. 83d St., New York. Large pages: on the left, quotations from leading physicians; on the right a group of pictures. Presents medical and surgical progress through animal experimentation, under "Surgery," "Physiology," "Pharmaceuticals," etc. No price given.

"Public Health Service Publications." List of publications issued, Jan.-June, 1935. U. S. Public Health Service, Washington, D. C. *Free*.

"Rural vs. Urban Longevity." *Statistical Bulletin*, Metropolitan Life Insurance Co., New York, N. Y. July, 1935.

"Safe Milk: A Public Health Measure," in *Dairy Council Digests*. National Dairy Council, 111 N. Canal St., Chicago, Ill. June-July, 1935. No price is given, nor the address of N.D.C.

"Suggestions for Reading in Public Health Nursing." A new edition of list of publications of National Organization for Public Health Nursing, 50 W. 50th St., New York, N. Y. *Free*. Professional and organization topics, with section on publicity.

MAGAZINE ARTICLES

"Medical Care for the Unemployed." Los Angeles County to give free services to its 400,000 idle. *Literary Digest*, 354 4th Ave., New York, N. Y. Aug. 10, 1935. 10 cents.

"Playing Safe," by E. R. Grannis (safety); "Spare the Mother," by E. S. Enochs (maternal mortality); "When Illness Comes," by K. B. Oettinger. *Parent-Teacher Magazine*, 1201 16th St., N.W., Washington, D. C. Aug., 1935. 15 cents.

"Where Every Child Gets Dental Care—and the Dentist Gets Paid!" by C. P. Streetor. *Farmer's Wife*, St. Paul, Minn. Sept., 1935. Copy free.

MOTION PICTURES

"The Greatest Mother," Red Cross picture, is available, sound or silent, 35 mm. or 16 mm., rental or purchase. Apply direct to W. J. Ganz Co., 19 E. 47th St., New York, N. Y.

Moving rapidly through views of Red Cross services, with the tempo of the "March of Time" films, the movietone illustrates strikingly the type of activities in which Chapters throughout the nation are engaged. Actual scenes of disaster, showing rescue of flood refugees, feeding by Red Cross Chapters, and dramatic force of flood waters, hurricanes and the like, bring home with force the fine accomplishments of the volunteers under Red Cross direction.

The work of the public health nurse, of the Gray Ladies and others in hospitals and in their contacts with disabled war veterans, are depicted.

"The Mosquito: Public Enemy." Sound, 2 reels. U. S. Department of Agriculture, Washington, D. C. Discusses the mosquito as a pest affecting man and beast, varieties and life history, safeguards and methods of control.

"Pulling Teeth With a Movie Anesthetic," by R. Arell. *Trained Nurse*, 468 4th Ave., New York, N. Y. Aug., 1935. 20 cents. How a dentist uses overhead movies to distract child and adult patients. For clinics and institutions?

Current Releases of Non-Theatrical Films and Film Notes, Department of Commerce, Washington, D. C., in May issue announced the following:

Several medical pictures, by Medical Cinematographic Society. Apply to: S. A. Bloch, 1865 52d Street, Brooklyn, N. Y.

"Milk the Master Builder," and "Preventing the Spread of Disease." National Motion Pictures Co., Mooresville, Ind.

RADIO

"On the Air." National Broadcasting Co., 30 Rockefeller Plaza, New York, N. Y. A promotion pamphlet. Text and pictures give an interesting review of radio history.

Recent health broadcasts reported to us are listed below.

Baltimore City Health Department:

Jerry Junior is ready for school. Sleep. Vaccination. Do it now. Mr. Strong inquires about infantile paralysis (dialogue). Infant care during hot weather. The black widow spider.

Illinois State Department of Health broadcasts over WHFC and WGN. Some topics:

Lockjaw a summer-time hazard. The ubiquitous mosquito and its relation to man. The "outer" and "inner" man on vacation. Foods, freight and advertising.

Minnesota State Medical Association broadcasts every Tuesday, 11:15 A.M., over station WCCO, Minneapolis and St. Paul. Some topics:

Getting ready for school. Diet and health. Shingles. Carhuncles. Foreign hodies in the eye. Pre-natal care. Ticks and disease. Women in cancer education.

Ohio State Department of Health broadcasts regularly over 4 stations in Columbus: WOSU at 2:30 P.M., Mondays and Tuesdays; WBNS at 1:30 P.M., Thursdays; WCOL at 2:00 P.M., Thursdays; WAIU at 4:15 P.M. every Wednesday. Some of the topics:

The diagnostic chest clinic. Health of the school child. Diphtheria. How your Health Department is meeting your problems. Debunking the medicine chest. Conservation. Do we eat to live? Undulant fever and psittacosis. The school nurse. Evolution of the bath. Am I worthy the name "Good Parent"? Health insurance. Typhoid vaccination: its utilization as an individual safeguard. Tuberculosis control and the school child. Maternal and child hygiene program under the social security act. Carbon-monoxide poisoning. Hidden hunger. Just teeth. What have you on deposit in your health bank?

SCHOOLS

"A Project in Rural School Health Education," by R. E. Grout. Reprint of 4 articles. *Milbank Memorial Fund Quarterly*, 40 Wall St., New York, N. Y.

The latest venture in poster contests is sponsored by the Indiana Tuberculosis Association (130 E. Washington St., Indianapolis), and associated organizations. The plan will not help to interpret any particular aspect of health, since

The poster theme is left largely to the student but should be classified under one of the following subjects (which range from "Food and nutrition," to "Sex character education").

BOOKS AND REPORTS

What You Should Know About Heart Disease—By Harold E. B. Pardee. 2d ed. Philadelphia: Lea & Febiger, 1935. 127 pp. Price, \$1.50.

The author has written an authoritative presentation of many of the aspects of diseases of the heart. His style is simple and understandable for the layman. The tone of the book is helpful and not alarming. The author clearly states that there are many diseases of the heart, and yet he clings to the old title of Heart Disease. It seems to the reviewer that it would have been better if he had changed the title of the book to "What You Should Know about Diseases of the Heart." It is very important that this newer conception be disseminated widely.

It is questionable whether in a book for the layman it is desirable to include instructions for diet and diet lists. It has always seemed to the reviewer that the writer of such a work should be scrupulously careful to avoid giving information that may tempt the patient to treat himself without proper medical supervision.

These are the only criticisms of the book. It is undoubtedly a valuable contribution in its own limited field.

EDWIN P. MAYNARD, JR.

Epidemics and Crowd Diseases: An Introduction to the Study of Epidemiology—By Major Greenwood, D.Sc., F.R.C.P., F.R.S. New York: Macmillan, 1935. Price, \$5.00.

In his chapter on diphtheria, Major Greenwood digresses to say: "Just as the enjoyment of detective fiction (of which I am a passionate admirer) is marred by foreign and unfamiliar at-

mosphere—one pines for the fictitious Scotland Yard when one is conducted through the fictitious Sûreté—it is (to me) easier to follow epidemiological plays when the characters move on a familiar English stage." Add that the author is the distinguished President of the Royal Statistical Society, and one has the keynote to this book. It conforms perfectly to the classical lines of British statistical epidemiology.

The first part is an historic review of the efforts of medical philosophers—Hippocrates, Galen, Dr. Caius, Fracastori, Sydenham, and others—to discover the "laws" governing the origins, movements, and distributions of "crowd" diseases. They failed, Major Greenwood maintains (not because they were attempting to bridge the chasm of exact knowledge by sheer force of intellectual effort, not because the invisible world of microscopic and ultra-microscopic parasitic forms of life had not yet been revealed, not because of the lack of development of the experimental method—but) because of the lack of a vital or medical statistical system codifying experience. This much needed statistical methodology was finally developed by the English school in the 18th and 19th centuries particularly as a result of the famous Bills of Mortality and the labors of John Graunt and William Farr. The biometricians—Quetelet, Francis Galton, Karl Pearson, Sir John Brownlee—led the way in perfecting the technic of analysis of the mass data of disease. The author admits that, so far, this new statistical calculus has failed to solve the problems of secular variation, change of type, method of spread, which the old pneumatists and other epi-

demologists who lived "before the deluge" speculated about, but he has great hopes for the future. He rightly points out that in contributing methods this school has had a profound influence on medical science in general. In commenting on this section of the book it is interesting to note that he regards Pettenkofer as a great epidemiologist and does not even mention John Snow.

He concludes the first portion with a chapter briefly reviewing the contributions of experimental epidemiology, and three on what he terms the "procatartic" (or predisposing) causes of illness—nutritional, occupational and psychological. He terms his treatment of these subjects superficial and incomplete,—with which we agree. After devoting several pages to a discussion of the soul-body relationship and the possible influence of mind upon illness he concludes: "It is certainly not my business as an epidemiologist to expound psychology of which I know little or metaphysics of which I know even less."

In the second part Major Greenwood finds it his duty to apply the general principles of epidemiology to particular cases of crowd diseases among men. Apparently he means by "general principles of epidemiology" the methods of statistical analysis of mass data. He selects for this purpose the typhoid group, cholera, typhus, measles, diphtheria, scarlet fever, smallpox, plague, epidemic diseases of the central nervous system, influenza, venereal diseases, tuberculosis, and cancer. His treatment is largely an historic one, tracing the earliest origins, epidemic movements and some of the distributions of each disease. He makes no effort to give a complete concept of the host-parasite relationships involved in the infectious diseases on the basis of present-day knowledge.

The material which he presents is selected casually to illustrate the application of the statistical technic.

Incidentally he devotes two chapters to a discussion of whether Sir John Simon was correct in his apotheosis of Edward Jenner as an Ideal Philosopher or whether Charles Creighton was more correct in regarding him as the Complete Rogue, and gives an illuminating account of the circumstances surrounding the introduction of vaccination against smallpox.

The author is very largely absorbed with the variables which affect the human host. The bias is very decidedly for *homo sapiens*. Unfortunately there are no Bills of Mortality for rats, lice, and fleas. Parasites are generally referred to as *materies morbi*. The hereditary and "procatartic" causes of variability in virulence, infectivity, selectivity, etc., of bacteria and viruses receive little attention. The author is largely oblivious of the advances in exact understanding of the biology underlying infectious diseases made during the past quarter century. References of any sort are meager, but such as there are refer almost exclusively to English and German historical or statistical literature.

Withal, the book is delightfully written, rich in classical allusions, contains interesting historical material, and is an excellent introduction to the use of the statistical method in epidemiology.

KENNETH F. MAXCY

Community Programs for Summer Play Schools—By LeRoy E. Bowman. New York: Child Study Association of America, 1935. 48 pp. Price, \$.35.

This text is a study of the summer play school. It shows the need of more adequate child recreation and the opportunity for it. It discusses the history and comparative development of the summer play school program, and puts forth the suggested programs with advice as to organization, personnel, and plant equipment.

There are several interesting tables on the number and proportions of boys and girls enrolled in the principal "Social Agencies for Youth" in the states and leading cities of the United States.

This is a worth while summarization of a special phase of education.

CHARLES H. KEENE

Happy Health Stories—By Mildred H. Comfort. Chicago: Beckley-Cardy Co., 1934. 160 pp. Price, \$.70.

Children in school today ought to be intrigued into living a healthy daily routine if the many attractive books coming from the publishers can be a prophetic gauge. *Happy Health Stories* is another one of the attractive health readers on the market and its gay illustrations increase its appeal to children.

Another one of its assets is that the story-book children are engaged in delightful activities in a world of realities, such as picnicking, egg-gathering excursions, gardening, and marketing.

The book has been written for the fourth grade level, so the question regarding the grading of material for those young readers arises. It is prompted by such statements as:

Fruit juices were full of vitamins. They were cooling and refreshing.

Citric acids in case of thirst, fatigue and overheating.

A calorie is about the amount of heat needed to make a half teaspoonful of water one degree warmer.

Another reference is made to mineral salts. Are children of the fourth grade in our average urban and rural schools equal to coping with statements from the field of physics, chemistry, and dietetics, without some preliminary facts leading up to them?

The average fourth grade child has not a clear conception of vitamins. How many adults have? Too, if we are

talking to elementary grade children about vitamins, why dress it up in a spelling like Vita-Mins? However, as a supplementary health reader stressing foods and nutrition the book will be appreciated by many teachers looking for new material. ANNA B. TOWSE

Your Child Is Normal—By Grace Adams, Ph.D. New York: Covici, Friede, 1934. 241 pp. Price, \$2.00.

This book, covering the first 7 years of childhood, is not only written interestingly but should prove adequate and comforting to the average parent. It has an easy, facile style and a homey spirit which will carry it far into the emotional and intellectual graces of its readers. Many of the "child guidance" texts are written in the bias of a particular school of psychology and it is welcome to find that *Your Child is Normal* is free of such sectarianism. It is a surprise to know that normal, average childhood needs to be stressed—we have heard and read so much of its aberrations and vicissitudes.

Its opening chapter on The Normal Child and the Average Child gives lucid, concise, scientific data concerning norms of development which are too often assumed to be known. The discussion of masturbation, for example, is well done, calmly and clearly set forth. The author wisely takes the middle ground, avoiding those who would favor absence of inhibition and those whose prudery would drive them to forceful (and unsuccessful) repression of the child's biological curiosity. The quotation from Ellis (page 115) is to the point: "Sexual precocity, while by no means necessarily of evil omen, is less promising for future welfare than its absence."

The advice is timely, for there seems to be an inordinate stressing or, at least, encouragement of much sex curiosity rather than advice as to the simple meeting of questions as they arise.

Chapter XII gives practical examples of the "why" and "how" of these biologic questions as they come from the child.

The author has been true to her foreword: "I have tried . . . to present a picture of young childhood . . . which will still be recognizable to those who know children better in the natural environment of their own homes . . ." I commend the book heartily and trust that its comfortable logic will bring surcease to parents who, while wanting information, have been intimidated or repelled by the didactic bias of some other texts they may have attempted. MAURICE A. R. HENNESSY

Psychology and Health—By H. Banister, M.Sc., Ph.D. New York: Macmillan, 1935. 256 pp. Price, \$2.50.

Here is a volume that develops with care and readability the doctrine of eclecticism in the application of psychology in medical practice. The author amply outlines the theories of Freud, Adler, Jung, Janet, and others, not in the terms of a protagonist or special pleader but rather as one who is seeking with intelligent criticality all possible common factors that may represent the residua of truth. The contents as a whole are of service to public health officials only to the degree that psychology enters into the fostering of personal health. The entire subject of the psychoses, however, is omitted as the therapy involved is so questionable, but there is a clear discussion of the psychic difficulties that follow a variety of physical illnesses.

The preventive aspects of mental disorder which concern public health administrators are emphasized in the last chapter in terms of education which has as its goal a well integrated character based upon strong and well adapted sentiments. Throughout, stress is placed upon the sentiment forming

tendency in terms of attraction and repulsion based upon pleasant and unpleasant feeling tone. While to a large extent temperament is regarded as particularly affected by the endocrines Banister recognizes that the glands are subject to many elements derived from the environment as well as from personal experiences. The protective strength of sentiments in stabilizing of character arises when they are fixed upon objects that tend toward permanence and are unlikely to be lost.

It is rather interesting to find that the author deems psychology somewhat shocked by psychoanalytic conclusions because, as he interprets it, psychology has not rejected the false nor absorbed the true elements that may have arisen from psychoanalytic doctrines. Psychology cannot be shocked but some psychologists may be timid, conservative, or critical in relation to theories difficult to substantiate in a satisfactorily scientific manner.

All public health officials will agree that mere knowledge in itself is not a preventive and may perhaps agree that public health service would be improved if individual citizens understood the relation of sentiments to socially approved activity. Certainly the major proportion of the difficulties in public health arise from an indifference in sentiment toward the practical meanings of public health work. There exists a definite hazard to the general public well-being, as a result of the incidence of mental instabilities, and psychiatric disorders. Probably the public is penalized economically and socially because too many individuals suffer from insufficient integration of sentiments and character in terms of their responsibility for themselves, their family, or their community. Hence it is the indirect influence of the psychological approach and the implications of a rationally adapted psychology that may be of interest to

public officials, whose specific problems concern masses of men rather than individuals.

Whatever improves the mental health of individuals lightens the tax burden and diminishes the tensions of living that are subversive of group welfare.

IRA S. WILE

Training in Psychiatric Social Work at the Institute for Child Guidance, 1927-1933—By Sarah H. Swift with a Foreword by Lawson G. Lowrey, M.D. New York: The Commonwealth Fund, 1934. 177 pp. Price, \$1.75.

This little book, as the title indicates, describes and discusses the psychiatric social work training program at the Institute for Child Guidance, New York City, during the years 1927-1933.

Psychiatric social work is relatively young and so is the field of child guidance. It is within these areas of activity that the volume under review concerns itself. Chapter I therefore appropriately discusses "Changes in Concepts of Training in Psychiatric Social Work." The changes have varied with the current trend of thought in psychiatry and also with the development of psychiatric social work as an entity. "Training is naturally affected by these shifts in emphasis." Psychoanalysis of the social worker herself is a factor in the shift in emphasis, sometimes causing the worker to assume total responsibility for the case. Miss Swift does well to query whether *shared* therapeutic responsibility will be abandoned. Seemingly *directive* responsibility has already passed from the psychiatrist. Probably the last sentence in this introductory chapter gives the key to the book. "It is in this direction, then, that the essential art of training lies, and while we should not *wish* to minimize the value of accumulated knowledge and

development of skills, it is only through our own *wish* to grow and mature that we can achieve the fundamental strength and perspective which may serve to stimulate in others the *wish* to develop a creative fulfillment in their own terms" (*Italics mine*). *Wish* unfortunately need not lead to *wisdom*.

Miss Swift has done a good job in discussing the program of training at the Institute as it relates to the utilization of case material and the supervisor-student relationship. This part of the book is of value to all who are interested in a training program in psychiatric social work. The examples given of individual training experience clearly and succinctly set out the differences in the human material under training. But one may well question whether a philosophy of case work that places major emphasis on the solution of problems by means of a dynamic relationship which will cause "the development in the student of an ability to 'resign her reliance upon social norms, moral standards and sound treatment plans, in favor of limited treatment ends and the stimulation of growth processes within the individual which may carry him she knows not where' may be considered the criterion of success."

However, Miss Swift is not unmindful of the fact that different emphasis on case work responsibility and objectives in treatment might exist in other clinics and that "in so far as such differences do exist the training emphasis will vary." Hers is an account of the work in one clinic and she undoubtedly has given a fair report of the work done there.

Such a book as this one has value. It tends to cause others to come to grips with a most important field of training—psychiatric social work—and with the philosophy underlying it.

HENRY C. SCHUMACHER

Lilly Research Laboratories. Dedication. Indianapolis, Ind., 1934. 128 pp.

The dedication of the Research Laboratories of Ely Lilly and Company, October 11 and 12, 1934, carried to Indianapolis a remarkable gathering of scientific men, including four Nobel Prize winners. There were a number of addresses by notable men.

The present volume is a collection of the addresses made on that occasion, including the address of welcome by the head of the firm, Mr. Eli Lilly. Scientific addresses were given by Dr. Irving Langmuir, Sir Frederick Banting, Sir Henry Dale, Drs. Elliott P. Joslin, George R. Minot, Frank R. Lillie, George H. Whipple, Carl Voegtlin, George H. A. Clowes, and others.

The volume is beautifully printed and illustrated and ends with a list of those who attended. It is valuable not only on account of the addresses given but also as a souvenir of an unusual character.

MAZÛCK P. RAVENEL

Maryland State Department of Health Report of Bureau of Sanitary Engineering—1934—By *Abel Wolman, Chief Engineer.*

This report is full of outlines of original technical studies of the Engineering Division of the State Health Department and a summary of the various activities of the Bureau.

It is pointed out that the incidence of typhoid fever continues on a downward trend.

Approximately \$4,400,000 worth of plans for work were submitted to the department for review and the major portion of the total expenditures were financed through the aid of the Emergency Public Works and the Civil Works Administration of the Federal Government.

An outline of the work done by communities during the year 1934 is listed under the following headings: Water

Supply & Sewerage; Metropolitan Districts; School; Camps, Swimming Pools, Summer Resorts; State Institutions, and Sealing Abandoned Coal Mines.

Approximately half the report is given over to a summary, in some little detail, of special technical studies under the following headings: Water; Sewerage; Industrial Wastes; Stream Pollution; Industrial Hygiene; Miscellaneous and Oyster Survey.

An example of the type of studies made is shown by the studies that were carried out under the heading of "Water." These studies included:

1. The study of the "internal corrosion of distributing mains on the Cumberland supply"
2. The "maintaining of chlorine residuals in remote sections of the Hagerstown distributing system"
3. The "efficiency of a zeolite iron removal unit of 27,000 gallons capacity"
4. The preliminary study of the water supply of LaPlata with reference to some "objectionable characteristics of the water"
5. Study of the "new Pines-on-Severs iron removal plant"
6. Study of the "turbidity and iron stain difficulties" existing in the Epping Forest water supply
7. Studies "to obtain complete removal of iron and lighten the load on the pressure filter by improving the settling characteristics of the floc" on the Sparrows Point water supply

It is stated that activated carbon is applied to the water for taste and odor control at 13 supplies, placing Maryland among the leaders in the use of activated carbon for taste and odor control of the public water supply.

Special studies have been made under each of the above headings comparable to the studies made under the water supply heading.

A study of this report by the Bureau of Sanitary Engineering of the State Health Departments, as well as Municipal Health Departments should be stimulating to those engaged in this branch of public health work.

ALFRED H. FLETCHER

Nursing Mental Diseases—By *Harriet Bailey*. (3rd ed.) *New York: Macmillan*, 1935. 258 pp. Price, \$2.50.

Not much comment needs to be made on this splendid text in its third edition, as most nursing schools are familiar with the earlier editions and know their value. This one is very similar in content to the earlier issues only it has been simplified. For instance, the introductory chapter on psychology has been omitted as there are good psychology texts for nurses available now.

A brief summary of personality development and alteration is given in this text for the first time to emphasize the importance of understanding mental reactions in order to nurse mental disease patients more efficiently.

Mental hygiene and the preventive aspects of mental disease are dwelt on in a way to please all public health workers.

The whole book is eminently practical because it is written by a nurse who knows from long years of practice what she is talking about.

EVA F. MACDOUGALL

A New Deal in Liquor: A Plea for Dilution—By *Yandell Henderson*. *Garden City, N. Y.: Doubleday, Doran*, 1935. 239 pp. Price, \$2.00.

This is an interesting book containing a wealth of material regarding alcohol as a social and physiological problem. The author makes points which apparently are understood neither by the general public nor by our legislators. The law fixes the same tax on the "proof gallon" as on the "wine gallon when below proof," which in his opinion amounts to taxing the water with which alcohol is diluted, taking away the incentive to dilute spirits, and promoting strong liquors.

He says that America has a liquor problem unlike that of any other coun-

try. American life is deficient in such social pleasures as are typified in the German beer garden. He objects to the sale of distilled liquors over the same bar as beer. He believes that the solution of the liquor question for us lies in the consumption of the milder alcoholic beverages. We should regulate the sale of spirits somewhat as we do that of opium, and of lighter beverages as we do tobacco.

The introduction of beer in the third quarter of the last century reduced the consumption of spirits by one-half. The consumption of wine has remained nearly stationary and at a low figure for several generations, and there is no indication of an increasing taste for wine. Unlike many other peoples, we do not take alcohol with our meals, but drink before and between meals.

The author holds that alcohol becomes seriously habit forming and harmful only when it reaches between 15 and 20 per cent by volume, and the higher the concentration, the greater the injury to the individual as well as to society. By confining drinking to beverages below 15 to 18 per cent by volume the peculiar American problem would largely disappear.

The book contains much interesting history. There are two appendices, the first of surpassing interest, being "An Inquiry into the Effects of Ardent Spirits upon the Human Body and Mind," by Benjamin Rush, M.D., published in 1814; and the second, a summary of the Report of the Committee of Fifty, which made its studies between 1893 and 1903.

There is a short and interesting discussion of the use of euphorics, such as tea, coffee, chocolate, and certain other intoxicants; namely, the alkaloids. He holds that the comparison between alcohol and the alkaloids is not in the slightest degree overdrawn. This book is based on facts, and well worth reading and study. MAZYCK P. RAVENEL

Thinking About Marriage—By Roy A. Burkhart. New York: Association Press, 1935. 156 pp. Price, cloth, \$1.75, paper \$1.00.

This volume is a practical guide for the discussion of courtship and marriage with groups of young people. Every young person is absorbed by his thoughts on this subject and he gets surprisingly little sound guidance to support his natural high idealism. This author makes an objective approach which promotes thoughtful consideration. A skillful leader could bring to bear on such a group a large amount of biological and hygienic information.

This is a good example of the discussion group technic, a method which is seldom used by those in the field of public health. Wholesome sex behavior stands at the center of any effective program in venereal disease control and should not be overlooked by the sanitarian. If health officers generally would sponsor serious group thinking by young people under trained leadership we would have a fresh and constructive approach to this old problem. If someone is searching for a new idea in health education this fall this volume and the method which it proposes can be recommended.

REGINALD M. ATWATER

The Appraisal of Public Health Activities in Pittsburgh, Pennsylvania, 1930 and 1933—By Marian H. Ewalt and Ira V. Hiscock. Pittsburgh: Bureau of Social Agencies, Federation of Social Agencies of Pittsburgh and Allegheny County, 1935. 125 pp.

This appraisal of Pittsburgh's public health activities is an attempt on the part of the Federation of Social Agencies to provide a basis for better planning of community health organization and services. The appraisal was conducted under the auspices of a sponsoring committee of 21 represent-

ing all of the interested groups in the city. A committee of equal size was appointed by the Medical Society to assist and special committees to deal with such important functions as tuberculosis, maternity and child hygiene, and school hygiene were called into being.

The appraisal first orients the reader with the problems of population, climate, industries and economics of the community and then describes in considerable detail the organization and development of the public health program from 1929 through 1933 setting forth the interests of the many special agencies which participate to varying degrees in the local program. Chapters in the report are devoted to the discussion of the organization and conduct of services in each of the special fields pointing out problems and the present services and the needs. Specific and timely recommendations are made for the future conduct of the program in each field.

One is a bit surprised at the relative meagerness of the mortality and morbidity statistics, as one might expect in a city of this size reliable vital statistics would be available since early in this century. In a few instances, comparisons are made between figures for 1920, 1930 and 1933 of both cases and rates, which seem like meager data from which to draw conclusions.

The appraisal of services indicates that vital statistics, laboratory, acute communicable disease control, maternity hygiene, infant hygiene, general sanitation are all developed to 85 per cent or better. It is surprising to find that organized services for venereal disease supervision and control are practically lacking and that this is the weakest phase of the present public health program. Especially is this surprising since the state of Pennsylvania has had organized clinics in many counties.

The report sets up as special problems demanding attention the control of venereal infections, the development of a mental hygiene program, services for control of cancer and heart disease.

One looks at the end of the report for some general recommendations of the Federation as to the program which the community planned to follow in putting the findings of the survey and appraisal into effect. Apparently the Federation has not yet formulated any course of procedure. The conduct of

the appraisal, however, utilizing many groups of interested people in the city was no doubt planned to give them an intimate acquaintance with the problem and to fit them to carry on the responsibility of program planning.

It is believed that the report would be more thoroughly and extensively read if it had been printed with a type of a lighter face and the material had been less crowded on the page. One finds difficulty in reading it consistently for long periods. W. F. WALKER

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Modified Prone Pressure Resuscitation—From France comes this modification of the Schafer method, requiring the services of two operators. Increased air intake is claimed for it.

ANON. Modified Schafer Method of Artificial Respiration. J.A.M.A. 105, 8:609 (Aug. 24), 1935.

Poliomyelitis Vaccine—Formalin inactivated poliomyelitis virus is probably a safe vaccine and begins to develop demonstrable antibodies in about a week. The authors conclude, conservatively, that only further study will show whether sufficient and permanent protection is given. It may be said, however, that the limited experience in the face of epidemics indicates the value of vaccination. In a second paper in this interesting symposium, one author discusses steps which led to the present position.

BRODIE, M., and PARK, W. H. Active Immunization Against Poliomyelitis. New York State J. Med. 35, 16:815 (Aug. 15), 1935.

Supervising Vitamin D Milks—Discussing the necessary regulations for vitamin D milk to insure that the customer gets what he pays for, the author suggests that minimum limits of vitamin D might be established, that periodic tests be made, but that no statement of the number of units contained should appear on the cap.

BROOKS, P. B. Vitamin D Milk Control. New York State J. Med. 25, 15:776 (Aug. 1), 1935.

Controlling Communicable Diseases—The present-day attitude toward control measures against measles,

whooping cough and scarlet fever are admirably expounded in this symposium. Not new, but good.

ELEY, R. C., *et al.* Symposium on the Control of Certain Communicable Diseases. New Eng. J. Med. 213, 5:195 (Aug. 1), 1935.

Immunizing Babies Against Diphtheria—Evanescence of immunity to diphtheria in infants interferes with the response to vaccination with toxoid. Therefore, immunization should not be done without a preliminary Schick test, is the conclusion of this paper.

GREENGARD, J., and BERNSTEIN, H. Passive Immunity in Infants and Their Response to Diphtheria Toxoid. J.A.M.A. 105, 5:341 (Aug. 3), 1935.

Scarlet Fever Immunization—Experience in Philadelphia in protecting children against scarlet fever leads the author to urge its more widespread use.

HENRY, J. N. A Study of Active Immunization Against Scarlet Fever. J.A.M.A. 105, 7:489 (Aug. 17), 1935.

Placental Extract and Measles—Immune globulin was found in this study to be of definite value in the treatment, modification and protection against measles.

LEVITAS, I. M. Treatment, Modification and Prevention of Measles by the Use of Immune Globulin (Human). J.A.M.A. 105, 7:493 (Aug. 17), 1935.

Preventing Rabies in a Large City—Discussing control measures applicable to New York City conditions, the author points out the difficulties in enforcing muzzling and leashing orders, and urges that owners be made responsible for bites by their dogs.

Persons bitten should receive compensation whether or not the dog proves to be rabid.

OLESEN, R. Control of Rabies in New York City. Pub. Health Rep. 50, 33:1087 (Aug. 16), 1935.

Who Was It Who Used To Talk About Depression Benefits?—Children in families whose income has fallen to a low level have suffered most in the recent economic depression. This is the conclusion of a study of relative changes in height and weight from 1929 to 1933 in children of families in various economic strata.

PALMER, C. E. Height and Weight of Children of the Depression Poor. Pub. Health Rep. 50, 33:1106 (Aug. 16), 1935.

Medical Practice and Public Hygiene—Recounting how the medical profession coöperated in the public health programs of Maryland's local health departments, the author urges the necessity for closer coöperation everywhere.

RILEY, R. H. Preventive Medicine. J.A.M.A. 105, 8:555 (Aug. 24), 1935.

Rules for Communicable Disease Control—This is the latest revision of the standard regulations for the administrative control of the communicable diseases usually required to be reported in the United States.

SUBCOMMITTEE ON COMMUNICABLE DISEASE CONTROL, COMMITTEE ON RESEARCH AND STANDARDS, AMERICAN PUBLIC HEALTH ASSOCIATION. The Control of Communicable Diseases. Pub. Health Rep. 50, 32:1017 (Aug. 9), 1935.

A Modified Death Rate—Willcox makes death rates for states more comparable by "standardizing" for sex, race, nativity, and age. As a result the ranks of the various states change greatly, and the "scatter" of the rates is reduced.

WILLCOX, W. F. An Improved Method of Measuring Public Health in the United States. *Revue de l'Inst. Int. de Statistique*, I, 1935, (reprint).

ASSOCIATION NEWS

THE ANNUAL MEETING

OCTOBER 7-10 will find many of the readers of the *Journal* in Milwaukee for the 64th Annual Meeting. Nearly 300 papers and reports are listed on the program. Those who will not have the good fortune to hear them personally are reminded that the best ones will appear in the *Journal* during the year, and that all committee

reports will appear in the Year Book.

Readers are urged to watch their local newspapers for announcements of radio programs originating at Milwaukee during the week beginning October 6. At least one of the several periods arranged will be over a national network while others will involve as many as thirty stations.

A WORD TO THE THRIFTY

VERY few of us, at any time, will entirely disregard an opportunity to reap a financial benefit from thrifty buying or from careful and calculated investments. Why, then, do A.P.H.A. Fellows continue to overlook the gain inherent in Life Membership? They should do so no longer.

A careful study of the chart on the reverse page will reveal the savings which will accrue to Fellows by taking Life Membership at various ages. For example, a Fellow applying for Life Membership at the age of 40 will save a little over \$75. This saving (three-quarters of the cost of Life Membership) is of such proportion as to warrant careful investigation.

Beside the straight economical benefits, others accrue to Life Members: (1) annual payment of bills is onerous to some—Life Membership eliminates that; (2) in times of low income, a Life Member is assured of his continuation in the Association, thereby safeguard-

ing for all time his professional standing; (3) a Life Member can pride himself on the high type of professional spirit he has shown by investing in the future of public health work.

Life Membership dues need not be paid at once—the payments may be spread over a year from the date of election, which takes place at each Annual Meeting.

Some may ask—What is done with the dues of Life Members? They are set up in a Life Membership Fund entirely separate from other Association funds, and only the interest therefrom is used to carry the cost of each Life Member's participation in Association activities.

It must be obvious that the advantages of Life Membership far outweigh the disadvantages. The Committee on Fellowship and Membership, therefore, urges each and every Fellow to give serious thought to the desirability of applying for Life Membership.

DOLLARS SAVED BY THE PURCHASE OF A LIFE MEMBERSHIP

[In place of payment of annual dues]

IN THE AMERICAN PUBLIC HEALTH ASSOCIATION

Data furnished by the Metropolitan Life Insurance Company

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- Orville G. Brown, M.D., Dr.P.H., Balboa Heights, C. Z., Chief Health Officer, Panama Canal
- Frederick McD. Harkin, M.D., City Hall, Marquette, Mich., City Health Officer
- Wallace D. Hunt, M.D., 606 City County Building, Seattle, Wash., King County Health Officer
- F. Isabelle Kapp, M.D., M.S.P.H., 1459 Wythe Place, The Bronx, New York, N. Y., Director, Out-Patient Department, Lincoln Hospital
- Julian O. Long, M.D., Box 504, Belen, N. Mex., District Health Officer
- Charles Y. Moser, M.D., Terra Alta, W. Va., County Health Officer
- Dudley A. Reekie, M.D., Box 108, Somerset, Ky., Director, Pulaski County Health Department
- Alex B. Shipley, M.D., Tazewell, Tenn., Director, Claiborne-Grainger Health District
- H. H. Tuttle, M.D., Department of Public Health, Springfield, Ill., Superintendent of Health
- Dr. James S. Walton, 158 Guy Park Avenue, Amsterdam, N. Y., District State Health Officer

Laboratory Section

- Alexander M. Carr, M.D., Jamesburg, N. J., Medical Director, Applied Research Laboratories, Inc.
- Marcella J. Movius, B.A., 236 Hart-Albin Building, Billings, Mont., Laboratory Technician
- Royal C. Perkins, Ph.D., 201 N. El Molino, Pasadena, Calif., Laboratory Director, Biological Research Laboratories
- A. S. Rudolph, M.S., McKenzie, Tenn., Head, Department of Science, Bethel College
- Louis W. Sauer, M.D., Ph.D., 636 Church Street, Evanston, Ill., connected with Evanston Hospital
- Pauline Sterling, Grand Island Clinic, Grand Island, Nebr., Bacteriologist and Laboratory Technician

Vital Statistics Section

- Marian H. Ewalt, B.S., 519 Smithfield Street, Pittsburgh, Pa., Research Assistant, Bureau of Social Research, Federation of Social Agencies
- Margaret P. MacDonald, State Board of Health, Montgomery, Ala., Editor, Death Certificates

Isabel McCaffrey, A.B., Room 828, 50 W. 50 Street, New York, N. Y., Statistical Assistant, National Tuberculosis Association

Robert L. McLaren, State Department of Health, Des Moines, Ia., Director, Division of Vital Statistics

Gerda C. Pierson, 469 State Office Building, St. Paul, Minn., Director, Division of Vital Statistics, State Department of Health

Robert Riegel, Ph.D., University of Buffalo, Buffalo, N. Y., Director, Bureau of Business and Social Research

Public Health Engineering Section

George O. Pierce, State Department of Health, Minneapolis, Minn., Sanitary Engineer

Norman J. Radder, M.A., 35 E. Wacker Drive, Chicago, Ill., Secretary, Plumbing and Heating Industries Bureau

Henry W. Taylor, B.S., 11 Park Place, New York, N. Y., Consulting Sanitary Engineer

Industrial Hygiene Section

Edgar C. Barnes, B.S., Westinghouse Electric & Manufacturing Company, E. Pittsburgh, Pa., Industrial Hygiene

Leopold Brahdy, M.D., 1700 Municipal Building, New York, N. Y., Medical Expert, charge Workmen's Compensation of New York City

Richard B. L. Fleming, M.S., Hotel Webster Hall, Detroit, Mich., Industrial Health Conservancy Laboratories

Léonard J. Goldwater, M.D., 477 First Avenue, New York, N. Y., Chief, Occupational Disease Clinic, N. Y. University College of Medicine; Director, Student Health Service

Roy R. Jones, M.D., U. S. Public Health Service, Washington, D. C., Passed Assistant Surgeon, Office of Industrial Hygiene and Sanitation

Stuart F. Meek, M.D., 7900 Joseph Campau Avenue, Detroit, Mich., Director, Industrial Hygiene Department, Chrysler Corp.

Stephen E. Whiting, S.B., 1100 Park Square Building, Boston, Mass., Assistant Chief Engineer, Liberty Mutual Insurance Co.

John J. Wittmer, M.D., 4 Irving Place, New York, N. Y., Medical Director, Consolidated Gas Company of New York and Affiliated Companies

Food and Nutrition Section

James E. Fuller, Ph.D., Massachusetts State College, Amherst, Mass., Assistant Research Professor of Bacteriology, Massachusetts Experiment Station

Child Hygiene Section

Olive B. Cordua, M.D., 739-4th Avenue, San Diego, Calif., Director, Division of Child Hygiene, San Diego, City and County Health Department

Margaret Tyler, M.D., 195 Church Street, New Haven, Conn., Associate Professor, Obstetrics and Gynecology, Yale Medical School

Public Health Education Section

James M. Batchelor, M.D., City Board of Health, New Orleans, La., Superintendent of Public Health

Francisco M. Fernandez, M.D., 343 Ingraham Building, Miami, Fla., Secretary, Pan American Medical Association, Section on Ophthalmology

George R. Thompson, M.D., Luzerne, N. Y., Elected Member 1931

M. O. Heckard, M.D., Chicago, Ill., Elected Member 1907, Fellow 1922

C. St. Clair Drake, M.D., Jacksonville, Ill., Elected Member 1914

Francis C. Driscoll, A.B., Quincy, Mass., Elected Member 1934

Mrs. William L. Putnam, Boston, Mass., Elected Member 1915

VITAL STATISTICS DIRECTORY

THE first attempt, as far as we know, to compile a list of persons engaged in vital statistics work was undertaken this year by the Vital Statistics Section of the A.P.H.A. The Directory has been issued in mimeographed form and a copy has been sent to each member of the Vital Statistics Section.

It is believed that the directory will be useful as a source of reference in determining who's who in the field of vital statistics, and in stimulating and

promoting professional coöperation and loyalty to the American Public Health Association.

The directory should help to bring opportunities for recognition and advancement, particularly in the case of junior members of departments.

We will gladly furnish a copy to any member or Fellow of the Association who would like one. A charge of 50¢ per copy will be made to individuals not affiliated with the American Public Health Association.

NEWS FROM THE FIELD

ROYAL SANITARY INSTITUTE HEALTH CONGRESS AT BOURNEMOUTH

SANDOR HORWITZ, M.D., representing the Department of Health of the State of Illinois and the American Public Health Association at the Health Congress at Bournemouth, July 15-20, reports an attendance there of 1,084 delegates representing 23 foreign governments and authorities, 38 dominion and colonial governments and authorities, and 624 local authorities and educational institutions in Great Britain. In addition, there were 200 members and associates of the Royal Sanitary Institute in attendance excluding those appointed as delegates. Associates of the Congress and holders of guest tickets numbered 164.

At the Congress, 45 addresses and papers were read at fifteen meetings covering preventive medicine, architecture, town planning and engineering, maternity, child welfare and school hygiene, veterinary hygiene, national health insurance, hygiene in industry.

Special courtesies were extended to overseas delegates and a luncheon in their honor was held at the Royal Bath Hotel on Tuesday, July 16.

NEW HEALTH GROUP CREATED

PRESIDENT ROOSEVELT has created an interdepartmental committee to coördinate health and related welfare activities of the government, in line with the new Social Security Act. Saying in a formal statement that "there is increasing necessity for better coördination of the health activities of the Federal Government," Mr. Roosevelt named Josephine Roché, Assistant Secretary of the Treasury in charge of the Public Health Service; Oscar Chap-

man, Assistant Secretary of the Interior; M. L. Wilson, Assistant Secretary of Agriculture, and Arthur J. Altmeyer, Second Assistant Secretary of Labor.

The President's statement read:

In view of the passage and signing of the Social Security Bill there is increasing necessity for better coördination of the health activities of the Federal Government. I am, therefore, creating at this time an interdepartmental committee to give attention to this subject. As members of this committee I have appointed the following government officials: Josephine Roche, Assistant Secretary of the Treasury, chairman; Oscar Chapman, Assistant Secretary of the Interior; M. L. Wilson, Assistant Secretary of Agriculture, and A. J. Altmeyer, Second Assistant Secretary of Labor.

I am directing this committee to include within the scope of its work not only health activities, but closely related welfare activities as well. As its immediate task I am instructing this committee to assume responsibility for the appointment of special committees to be composed of physicians and other technically trained persons within the government service to study and make recommendations concerning specific aspects of the government's health activities.

I am confident that this procedure will facilitate the consummation of a series of appropriate coöperative agreements among the various departments of the government. I am also hopeful that in this way we can eventually bring about a complete coördination of the government's activities in the health field.

—*New York Times*, Aug. 16, 1935.

WHITE MICE FARM GIVEN GOVERNMENT

FORTY-FIVE acres of land in Maryland has been deeded to the U. S. Public Health Service by Mr. Luke Wilson, formerly of Evanston, Ill., for a white mice, rabbits and guinea pigs farm to facilitate research.

With the completion of some legal

formalities, it is stated that a \$100,000 Federal fund is available for constructing the first building.

RADIUM RESEARCH IN SWEDEN

THE battle against cancer in Sweden, which has already been aided by the million dollar jubilee fund subscribed at the time of the King of Sweden's 75th birthday, will now be further stimulated by a donation of 350,000 kroner (\$93,800) from a grateful patient at the Swedish Radium Home at Stockholm, the late Mrs. Maria Althainz. The income from the fund will be used for a professorship in radium therapy, the first holder of which will be Dr. Elis Berven, now chief physician at the Radium Home, founded by Dr. Gösta Forsell, the widely known radiologist.

Mrs. Althainz was successfully operated on at the Radium Home for a cancerous growth by Dr. Berven about six years ago. The cause of her death was not cancer.

The holder of the professorship should be free to devote his principal efforts to research, it is stipulated. The estate is to pay the inheritance taxes and the Swedish Government provide a pension. The Radium Home will be moved to new quarters at the Caroline Academy of Medicine in 1937, and there will be two divisions, one for medical radiology and one for radium therapy.

PHILADELPHIA CHILDREN IMMUNIZED

APPROXIMATELY nine thousand children under the age of 6 years were immunized against diphtheria in a campaign sponsored by the Philadelphia Department of Public Health in June.

In the last ten years the death rate from diphtheria in Philadelphia is said to have been reduced from 16.10 per hundred thousand of population to 1.09.

DR. GORDON TO STUDY SCARLET FEVER IN RUMANIA

JOHN E. GORDON, M.D., PH.D., of Detroit, member A.P.H.A., sailed September 21 from New York on an expedition to Rumania, where, in company with a staff of laboratory and field workers, he will undertake an extended study of scarlet fever.

For some months past Dr. Gordon has been working at the Rockefeller Institute for Medical Research in New York, studying special technics which may be applied to scarlet fever. Rumania has been chosen as the field for study because it lies in one of the very few portions of the world where scarlet fever still retains a high case fatality rate, deaths being in the vicinity of 10-20 per cent of the cases, in contrast to the average elsewhere of about 1 per cent.

It is significant that the health department of an American city thus reaches out to a remote part of the world for clues as to the cause of one of the more prevalent communicable diseases about which there has grown up much conflicting opinion and in which progress seems to have become arrested at a very incomplete level. It is understood that special attention will be centered on the cause of scarlet fever, with the possibility in mind that a parasite as yet undescribed may be discovered.

MISSISSIPPI ELECTS COUNTY OFFICERS

NEW County Health Officers in Mississippi are announced as follows:

- W. S. Martin, Carthage, Leake County
- William A. McMahan, Union, Newton County
- Albert P. Alexander, Como, Panola County
- George Lacey Biles, Sumner, Tallahatchie County
- Homer B. Watkins, Noxapater, Winston County
- Frank L. McGahey, Calhoun City, Calhoun County

SIR GEORGE NEWMAN HONORED

THE Medical Society of London presented the Fothergillian Gold Medal to Sir George Newman at its annual meeting, May 13.

Sir George, Honorary Fellow of the A.P.H.A., retired in March as Chief Officer of the British Ministry of Health and of the board of education. The medal is awarded by the Society every three years.

U. S. CHILDREN'S BUREAU DIVISION
HEAD APPOINTED

THE appointment of Ethel C. Dunham, M.D., to be Director of the Division of Maternal and Child Health of the Children's Bureau, U. S. Department of Labor, was announced by Katharine F. Lenroot, Chief of the Bureau.

Dr. Dunham, who has been on the Bureau staff since 1927, had been acting director of the division since December, 1934, when she was transferred to Washington from the Bureau's New Haven Branch. In New Haven she was engaged in original research and investigation on the medical aspects of neonatal mortality and morbidity.

Dr. Dunham succeeds Dr. Martha M. Eliot, who was promoted last December to be Assistant Chief of the Children's Bureau.—*Clearance*, Aug., 1935.

ANNA MARIA RHODA ERDMANN

PROFESSOR RHODA ERDMANN, Cancer Research worker, died August 24, at the age of 64. She was head of the Berlin Cancer Research Institute, founded by donations from the United States. She was the first German woman, it is stated, to lead a university institute independently.

She was a Professor, on the medical faculty, at the University of Berlin since 1922, and was the author of scientific books and articles.

MISSOURI PUBLIC HEALTH ASSOCIATION
MEETS

THE Missouri Public Health Association held its eleventh annual meeting in Kansas City, September 5-7.

Joseph F. Bredeck, M.D., D.P.H., Health Commissioner of St. Louis, member A.P.H.A., was inducted as President. Mrs. Elsbeth H. Vaughan, R.N., of St. Louis, F.A.P.H.A., was elected to represent the society on the Governing Council of the American Public Health Association. C. F. Adams, M.D., of Jefferson City, F.A.P.H.A., was reelected Secretary.

The meeting was well attended and leading health workers in the state participated.

Some of the speakers from outside the state were Dr. William DeKleine, of the American National Red Cross, Washington, D. C., F.A.P.H.A.; Eva F. MacDougall, R.N., of the Indiana State Division of Public Health, F.A.P.H.A.; Dr. Caroline Hedger, of the Elizabeth McCormick Memorial Fund; and Reginald M. Atwater, M.D., Executive Secretary of the American Public Health Association.

The 1936 Annual Meeting of the society will be held in Columbia, Mo.

AIR CONDITIONING SHOW

THE Fourth International Heating, and Ventilating Exposition, which is to be held January 27-31, 1936, in the International Amphitheatre in Chicago, Ill., is planned to be a pageant showing the advance of civilization in terms of the very air it breathes. Illustrated by means of the actual machines and processes in operation will be man's latest methods for the ultimate control of the weather in all seasons and climates.

The Exposition, which is held every two years, comes this year for the first time in Chicago. Previous expositions were held in Philadelphia, Cleveland, and New York.

NATIONAL ILLNESS SURVEY PLANNED

GEORGE ST. J. PERROTT, research associate of the Milbank Memorial Fund and statistician of the U. S. Public Health Service, will be the director of a national survey of chronic illness which is to be undertaken this fall with funds from the Works Progress Administration.

This health inventory is expected to yield information as to the extent to which ailments such as heart disease, rheumatism, diabetes, cancer, and digestive disturbances prevail in the United States, and the effect of such illnesses on economic and social conditions. The present study will later be correlated with data obtained previously by the Public Health Service in an intensive study of the importance and effect of chronic ailments on the capacity of the patient and family to remain self-supporting.

It is planned to obtain some of the necessary information from the records of hospitals and sick-benefit associations, and also to make a house-to-house canvass of 750,000 families in 19 states, selected as representative of the general population of various income levels. Besides chronic illness, data will be collected on physical disabilities, such as blindness, deafness, loss of limbs, or other crippling handicaps. In addition, an inventory will be made of the medical and nursing facilities available throughout the country, and information gathered as to the extent to which the canvassed population availed themselves of the existing public health and medical services.

The states to be included in the inventory are: Washington, Oregon, California, Utah, Minnesota, Missouri, Illinois, Michigan, Ohio, Pennsylvania, Maryland, Virginia, New York, New Jersey, Massachusetts, Georgia, Alabama, Louisiana, and Texas.—*News Digest of the Milbank Memorial Fund*, Sept., 1935.

WEIGHT REDUCER CAUSES BLINDNESS

BLINDNESS from the use of dinitrophenol for reducing weight has not stopped the use of the drug in spite of warning, says W. G. Campbell, Chief of the Federal Food and Drug Administration.

The eye cataracts observed in dinitrophenol poisoning develop with a rapidity and malignancy hitherto unknown, and result in total blindness within a comparatively short time. This drug may produce acute poisoning, followed by death.

The Food and Drugs Act, according to Mr. Campbell, is practically inoperative against this public health hazard. He says, "The only application of the law to these products is through some misstatement of fact or some false and fraudulent curative claim in the labeling. In any event, the law can be invoked only when the product has been transported across a state line."

TEXAS ASSOCIATION TO MEET

THE Texas Public Health Association will hold its Thirteenth Annual Meeting in Waco, Tex., October 16-18, at the Roosevelt Hotel.

Dr. B. E. Pickett, President of the association, plans what he hopes will be a worthwhile program.

WESTCHESTER HEALTH ASSOCIATION
INCORPORATED

INCORPORATION of the Westchester Tuberculosis and Public Health Association—at White Plains, N. Y.—was announced on September 14, "to facilitate the building up of relief funds of the organization."

James A. Tobey, Dr.P.H., of Rye, N. Y., F.A.P.H.A., who previously headed the association, has been elected President of the Corporation. Mrs. Susan W. Baker is Executive Secretary; and Edward M. Ames and James E. Bryan are Treasurer and Secretary respectively.

PERSONALS

OWEN E. PUCKETT, M.D., of Carlsbad, N. M., member A.P.H.A., has been appointed Health Officer of a district made up of Eddy, Lea, and Chaves Counties, N. M.

MICHAEL M. DAVIS, M.D., Director of Medical Services for the Julius Rosenwald Fund, Chicago, Ill., F.A.P.H.A., received the award of the Squires Prize for original investigation in the field of sociology. The award is made once every five years by Columbia University.

DR. FRANCIS W. HEAGEY, of Omaha, was elected President of the Nebraska Tuberculosis Association at the recent annual meeting.

DR. GAIL E. MILLER, of Lima, has been named Health Officer of Allen County, Ohio, on a part-time basis, to succeed Dr. John J. Sutter, member A.P.H.A., who served 16 years as full-time Health Officer.

DR. THOMAS E. GIBSON, of Mount Pleasant, Mich., has been appointed Health Officer of Genesee County, succeeding Leslie A. Lambert, M.D., of Flint, member A.P.H.A., resigned.

HAROLD JACKSON DAVIS, M.D., Assistant Director of Local Health Administration of the New York State Department of Health, Albany, N. Y., has been assigned as part-time consultant in medical care to the Works Progress Administration. Dr. Davis is a Fellow of the A.P.H.A.

HALBERT LOUIS DUNN, M.D., of Minneapolis, Minn., member A.P.H.A., has been appointed to the post of Chief Statistician in the Division of Vital Statistics of the U. S. Department of Commerce at Washington, D. C.

ALFRED D. GREGG, M.D., of Liberty, N. C., member A.P.H.A., has been appointed Health Officer of Edgecombe County, to succeed Dr. Rembert E. Broadway, of Tarboro, resigned. Dr. George H. Sumner, of

Asheboro, member A.P.H.A., has been appointed Health Officer of Randolph County, to succeed Dr. Gregg.

LESLIE T. WEBSTER, M.D., of the staff of the Rockefeller Institute for Medical Research, New York, member A.P.H.A., has recently received a prize of 1,000 Swiss francs awarded by the medical faculty of the University of Berne, Switzerland, in recognition of his work on encephalitis.

DR. PHILIP S. JOSEPH, of Alice, Tex., has been appointed Health Officer of Jim Wells County, to succeed the late Dr. John S. Strickland.

DR. BERNARD W. PATTON, of Lebanon, Tenn., was recently made Health Officer of Wilson County, to succeed William D. Cagle, M.D., member A.P.H.A.

DR. J. WILL PAYNE, of Willowood, has been appointed Health Officer of Lawrence County, Ohio.

DR. CLAY E. COBURN, of Kansas City, was elected President of the Kansas State Board of Health, at Topeka, Kans., recently.

DR. MURRAY C. EDDY, of Hays, has been named Health Officer of Ellis County, Kans.

DR. KENNETH H. COLLINS, of Craigmont, has been appointed physician and Health Officer of Lewis County, Idaho, succeeding Dr. Eli Taylor, resigned.

DR. FLOYD R. TOWN resigned recently as Health Officer of Jackson, Mich., after 16 years' service to become Health Commissioner of Isabella County.

DR. EDWARD A. SCHILZ, of Grand Ledge, Mich., has been appointed a member of the Michigan State Council of Health, to succeed Dr. William E. McNamara, of Lansing; and U. G. Rickert, D.D.S., of Ann Arbor, will succeed the late Chalmers J. Lyons, D.D.S.

DR. JESSE LYNN MAHAFFEY, of Had-donfield, N. J., was reelected Director of the New Jersey State Department of Health for four years. Dr. Irvin E. Deibert, of Camden, was elected President.

DR. CLARENCE H. WHITE, of Kenansville, N. C., has been named District Health Officer, with jurisdiction over the health boards of Avery, Yancey, and Watauga Counties.

CONFERENCES

- Sept. 30-Oct. 4, American Hospital Association, St. Louis, Mo.
- Sept. 30-Oct. 4, 21st National Recreation Congress, sponsored by the National Recreation Association, Chicago, Ill.
- Oct. 3-5, Association of Military Surgeons of the United States, New York, N. Y.
- Oct. 4, 5, Joint Meeting of the New England and New York State Sewage Works Associations, Schenectady, N. Y.
- Oct. 5, Round Table Conference of State Supervising Nurses, Milwaukee, Wis.
- Oct. 5-7, Conference of State Sanitary Engineers, Milwaukee, Wis.
- Oct. 7-10, Sixty-fourth Annual Meeting of the American Public Health Association, Milwaukee, Wis. Headquarters: Hotel Schroeder.
- Oct. 7-10, Annual Meeting of the American Association of School Physicians, Milwaukee, Wis.
- Oct. 7-10, Meeting of the American Association of State Registration Executives, Milwaukee, Wis.
- Oct. 7-10, Meeting of the International Society of Medical Health Officers, Milwaukee, Wis.
- Oct. 7-10, State Laboratory Directors Conference, Milwaukee, Wis.
- Oct. 7-10, Conference of Wisconsin Health Officers, Milwaukee, Wis.
- Oct. 8-11, Meeting of the Association of Dairy, Food and Drug Officials, Milwaukee, Wis.
- Oct. 10-11, Meeting of the International Association of Dairy and Milk Inspectors, Milwaukee, Wis.
- Oct. 12-19, Seventh Pan American Child Congress, Mexico City.
- Oct. 14-18, 24th Annual Safety Congress, National Safety Council, Inc., Louisville, Ky.
- Oct. 28-31, 18th Annual Meeting, American Dietetic Association, Cleveland, O.
- Nov. 1, Mid-Year Meeting of the New York State Association of Public Health Laboratories, at the State Laboratory, Albany, N. Y.
- Nov. 1, First Session of the Society of Illinois Bacteriologists, Chicago, Ill.
- Nov. 1, 2, School Health Conference, sponsored by the Department of School Health and Physical Education of the National Education Association, Philadelphia, Pa.
- Nov. 15, 16, Sixty-first Annual Meeting, New Jersey Health and Sanitary Association, Hotel Berkeley-Carteret, Asbury Park, N. J.
- Nov. 19, 20, Annual Meeting of the Southern Branch, American Public Health Association, St. Louis, Mo.
- Dec. 30-Jan. 4, 1936, Winter Meeting of the American Association for the Advancement of Science and Associated Societies, St. Louis, Mo.
- Jan. 27-31, 1936, Fourth International Heating and Ventilating Exposition, Chicago, Ill.
- Apr. 22-25, 1936, National Tuberculosis Association, New Orleans, La.
- May 11-15, 1936, American Medical Association Convention, Kansas City, Mo.
- July 27-31, 1936, Second International Congress on Mental Hygiene, Paris.
- Sept. 8-10, 1936, International Union Against Tuberculosis, Lisbon, Portugal.

Public Health at the Cross-roads^{*}

E. L. BISHOP, M.D., F.A.P.H.A. (*Life Member*)

*President of the American Public Health Association; Director of Health,
Tennessee Valley Authority, Knoxville, Tenn.*

THIS has been an eventful year in the history of the public health movement. For the first time the importance of public health protection as an element in national security has been fully recognized by expression of a national policy for the strengthening of state and local health agencies. Passage of the Social Security Act by the last Congress presents the public health profession of this country with the greatest opportunity to establish constructive programs of health service that has been given to any group in our history.

It is possible, under this policy and under appropriations already authorized though not yet made, to plan and execute a public health service, comprehensive in its organization, balanced in its programs, and relatively complete in its extent. As Dr. Ravenel has so pointedly emphasized, the American Public Health Association is the twin of modern preventive medicine, for both

came into being with the birth of our present conceptions of the spread and prevention of disease. Today, our twin has grown to man's estate and offers us a vast body of scientific knowledge to which both the natural and medical scientist constantly contribute added increments. For much of this knowledge, we, as yet, have found only incomplete facilities of application, but the chance of closing the gap between the acquisition and application of knowledge is at hand. I propose, tonight, that we rededicate ourselves to this purpose.

Epoch making as are the provisions of the Social Security Act in its shifting of our sense of values toward humanity and the conservation of vital resources, the country is to a very large degree prepared for them. For a generation the foundations and philanthropic institutions have carried on experimental work in public health administration, the training of personnel, and the development of proving grounds for teaching new principles and methods in the application of knowledge. This Association has, through its sections and

^{*} Presidential Address, delivered at the First General Session of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

standing committees, proved itself an invaluable instrumentality in the acquisition and interchange of information relative to public health procedure. No country of the world possesses a more able and efficient health agency than our own United States Public Health Service, and nowhere can be found more cordial relations than exist between this federal agency and the individual state agencies. Though local health organizations are yet limited in extent, the combined efforts of the voluntary and official health agencies of the country have established beyond reasonable doubt the principles governing local health administration. The present need is to secure the universal application of these principles.

Every state has recognized the place of public health in the governmental structure by the establishment of some form of state health organization. It is obvious, therefore, that there exists not only a knowledge of program and procedure through which much of our present information may be applied, but there is also available a partial structure of organization which needs only strengthening, extension, and expansion to provide equal opportunity of adequate health service for all the people.

The establishment of a national health policy through passage of the Social Security Act, together with the existence of at least the elementary facilities for the application of knowledge, today places the public health profession of this country at the crossroads of opportunity. If its fullest possibilities are to be realized, this turning point in our history must be met in the spirit of highest idealism. Therefore, I am encouraged to restate four fundamental objectives which have been the subjects of our discussions through many years, and in which we can now advance further in achievement than at any time since the organization of the Association.

Equal opportunity for adequate health service for all the people is a capital objective. In a country so vast as ours with unequal distribution of population, natural resources, governmental income, and health situations, it must be perfectly clear that at present little equity exists in the opportunity for the prevention of disease and the achievement of health. Many studies, familiar to most of us, show the wide disparity in the pressure of both common and regional health problems. Moreover, frequent observations show that the region with the smallest financial resources is confronted with the largest need for health service.

The second major objective, and one fundamental to economy and good administration, is the development of a fully balanced and correlated national plan of program and procedure, with each of the three elements of government (federal, state, and local) assuming full responsibility for the functions it is best situated to perform. There is no need for overlapping and duplication. The field is too broad, the responsibility too large, and the existing machinery of organization too inadequate for any agency to fail in assuming its specific duty or to assume duty for the performance of which it is not properly situated.

The third and possibly the most important of all objectives is the establishment of standards of recruitment, education, and training for personnel groups, since no service is better than the people who administer it, nor can knowledge be applied by those who do not possess it. Public health must be made a career service in which standards of ability and professional qualification constitute the exclusive basis of preferment.

The fourth objective is the extension of basic research in both the acquisition and the application of knowledge, in order that the frontiers of our factual

information may be advanced far beyond their present limits. As yet, we have only touched the fringe of potential values, and present research must not only be continued, but extended into new fields if we are to obtain progressive improvement of the methods and measures we use in our daily tasks.

All of these objectives can be realized under the public health provisions of the Social Security Act if we are capable of translating potentialities into action. The Act very specifically provides for

. . . assisting states, counties, health districts, and other political subdivisions of the states in establishing and maintaining adequate public health service, including the training of personnel for state and local health work.

It further provides for allocation of funds on a basis of population, special health problems, and financial needs of the respective states; for formulation of rules and regulations governing allocation of funds by the Surgeon General of the U. S. Public Health Service, after consultation with a Conference of the State and Territorial health officers; and for the such increased investigation of disease and of problems of sanitation as will make of the U. S. Public Health Service one of the great research institutions of the world.*

What are the essentials to successful action?

I believe the American Public Health Association has the chance to render a service at least equal to and perhaps exceeding that of any official agency. It is the professional association of public health workers. It guides very

largely the thinking of the varied groups of professionally and technically trained people included in its ranks. It holds in its membership the real leaders of the public health movement of the country, and it is an admirable medium for the ready exchange of knowledge concerning current practices, procedures, and research. It should be the efficient servant of all its members, and its present organization is such that its effectiveness is constantly increasing. It should, and undoubtedly will, consistently engage in such self-study and provide such expansion as will further increase its usefulness and prestige.

Through the work of its sections and standing committees, it has made large contributions to the advancement of public health practice in this country, but it has a still larger contribution to make. The excellent service the Committee on Administrative Practice has rendered in systematizing health programs, and promoting of better program balance must be continued and expanded where essential, for studies in this field are vital to improvement of methods.

The Committee on Research and Standards must be strengthened by the provision of increased funds, that the main committee and its sub-committees may form critical boards of review and evaluation, a function similar to that fulfilled by certain councils of the American Medical Association. This committee, operating under the handicap of practically no budget, has rendered a valuable service, but has developed as yet only a small fraction of its potentialities.

Perhaps the standing committee of most immediate importance is that on Professional Education. Here will be determined very largely whether or not we shall realize the major objective of standards of education and training through which we may facilitate the evolution of the public health work of

*I have deliberately refrained from discussion of other fundamental provisions of the Social Security Act including that part providing for the maternal and child hygiene service, work for crippled children, and others, for the reason that the whole matter is one for discussion at a Special Session of the present convention and my purpose is that of illustrating an opportunity rather than discussion of the Act.

the country into a career service. The committee has made a beginning, but only a beginning. The work already accomplished, however, enabled the Conference of State and Territorial Health Officers to formulate professional standards to guide the expansion of public health work organized under the Social Security Act. No more important service could have been rendered by this Association. It is true the work up to now is relatively superficial and general in character, but it is the beginning of a task hitherto left undone, and the committee can do for this Association what the very vital Council on Medical Education has accomplished for the American Medical Association. Progressive improvement of standards must continue if we are to deserve recognition as a group to which the judgment of professional qualifications can be partially delegated. Already in Great Britain

. . . professional qualifications are usually judged on the basis of membership in professional societies. Thus the selection of chief officers and professional and technical officers is delegated in part to a private professional organization. The theory is that professional qualifications can be better judged by the persons engaged in the profession than by any outside group.¹

The nation-wide program of training, provided by terms of the Social Security Act, will be far reaching and can accomplish much in the improvement of public health work. The present conditions of haphazard employment of untrained or inadequately trained personnel can be transformed into a system whereby individuals deliberately train for a career in the public health service of some unit of government and, ultimately, we may look forward to the time when such work constitutes a career service in the best and fullest sense of that term. This program of training will do more to exclude partizanship and consideration of political

expediency from public health organizations than all the statutes that might be written, for it insures a service which will win public esteem because of its merit. Such a statement requires no proof. We have already shining examples of its truth in our own U. S. Public Health Service and in many state and local organizations. It is a fundamental step forward not only in the betterment of the public health, but in the betterment of government itself, for it recognizes the principle of trained public servants for public service.

Added to the formulation of objectives and the establishment of guiding principles we shall have problems of organization. One of the most important of these is that of effective decentralization of service to the state and local health agencies, because a very fundamental policy, expressed in the public health title of the Social Security Act, is that of decentralization through the imposition of larger responsibility upon these agencies. We must be aware, however, that this carries with it an obligation to weld effectively the health service of all three elements of our government into a properly articulated whole. In this connection a resolution passed by the third annual convention of our Association in 1874 stands out as of exceeding interest. It provided that a committee consisting of a member from each state and territory of the Union be appointed to petition Congress at its next session to institute a Bureau of Health, located at Washington with a *branch at the seat of each state and territorial government*. A Bureau of Health has long since been created, but it seems to me rather fundamental to the success of our present efforts that well trained officers of the U. S. Public Health Service be made available to each state for consultation and field service in immediate program development, in personnel training and for as-

sistance in the planning of ultimate objectives.

Those of us who serve or have served as state health officials fully realize the value of such aid, and most of us could cite a number of examples in which it has resulted not only in shortening by a decade or more the period required for the development of effective organizations, but also in the planning of much better balanced and broader programs. Financial aid is not the only prerequisite of good work. Persons must translate money into accomplishment.

While all of our states have some form of state health organization, in many instances appropriations and personnel are insufficient to provide for even the most basic functions of a state health department. It is, however, in local health service that the most glaring deficiencies are shown, for of the more than 3,000 counties of this country, only 540 have provided even the foundations for whole-time health service, and some urban areas have organizations equal only to the most rudimentary requirements. It is in the state and local elements of our health machinery that the greatest structural weakness lies, and until these weaknesses are strengthened many sections of the country will be either partially or wholly without facilities through which the full values of present opportunities may be grasped. Individually and collectively we must exert our whole force in the effort to overcome these weaknesses. Hence a second organizational problem of extreme and immediate importance is that of closing these gaps through the establishment of properly organized health agencies where there are now no such agencies, and of increasing the adequacy of those which are inadequate.

As a group devoted to the service of humanity, we must become increasingly conscious that we are passing

through a renaissance of preventive medicine and public health, and that almost coincidentally with the birth of this Association, a new epoch began in the history of man's effort to survive the hazards of his environment and the menace of his fellow man. Our knowledge of the causative agents of disease, channels of infection, differential diagnosis, immunization and, even more important, the causes of good health, affords evidence that the human race fights a winning battle against the forces that would destroy it. This knowledge imposes upon us the responsibility of effecting a functional correlation wherever there is common interest and where administrative or organic union is inadvisable or impossible. The need of such correlation applies to all the categories of relationships—to the one governmental agency and another; to one professional group and others; to voluntary and professional associations—for all must, if they deserve survival and support, have the common objective of service to humanity.

Because of the greater importance of the immediate opportunity which the last Congress placed squarely before us as a responsibility, I have purposely refrained from detailed comment upon the affairs of the Association. There is, however, one point in connection with Association affairs which I should like to mention in conclusion.

I am sure you join me in holding for Dr. Kendall Emerson, our Executive Secretary for some years past, the deepest possible gratitude for his fine achievements in carrying the Association successfully through the most trying years since its organization, and that you, with me, have for him the most sincere affection. No human, however, could bear indefinitely the double burden of administering two great associations, especially with the problems of our Association so largely increased.

We are fortunate in having secured Dr. Reginald M. Atwater to continue, on a full-time basis, the fine service of Dr. Emerson. He, too, is a man we may all esteem for his fine attainments as an executive, a leader, and a friend.

Placing the secretaryship on a full-time basis could not have been done at a more opportune time in view of the importance of the work in relation to the matters considered throughout this discussion. I have every confidence that the affairs of the Association will prosper under his administration, and that it will meet its larger responsibilities with increasing effectiveness. In our support of his labors let us keep constantly in mind the statement of our first president, Dr. Stephen Smith, at

the Semicentennial Meeting in 1921:

May I be permitted reverently to suggest that our purpose has the same sentiment as was heard by the shepherds on the plains of Judea at the Nativity? Then the "good will to men" was announced to be the salvation of the soul from sin by divine appointment; while we now learn that salvation from the sins of the body must be effected by man himself, who created them.

Let us apply ourselves to the task with renewed vigor, and thus enable those who will greet the centennial anniversary of this Association to hear from sanitary officials the good news that the death rate of the year 1971 is limited to those afflicted with old age, or to disease or accidents unpreventable and incurable by any agencies known to science.

**Protect Your Home
from Tuberculosis
BUY
CHRISTMAS SEALS**

Buy Christmas Seals

THE girl of the 1860's never heard of Christmas Seals. But she knew about "consumption." It was rampant. Her chance of getting it was three times greater than it is today. Tuberculosis still takes 50 per cent more girls than boys between 15 and 24. To help protect our modern girls against this disease the Christmas Seal must continue its program of education and prevention.—The National, State and Local Tuberculosis Associations of the United States.

Economic Health and Public Health Objectives*

JOSEPHINE ROCHE, LL.D.

*Assistant Secretary of the Treasury, in Charge of Public Health,
Washington, D. C.*

AS we now begin to emerge from our recent so-called period of "emergency," a few lasting lessons have been learned, we hope, by those of us interested primarily in the advancement of human welfare.

One of them, resulting from our coming to grips, as we have, with unprecedented human denials and suffering, is how completely interwoven and interdependent our various responsibilities are in changing the old order. We have long talked about our age of specialization—the field of education, of industry; the field of child welfare, of health; the problem of dependency, delinquency and crime—and now we realize that our various fields are but small lots, separated from each other only by imaginary lines, in one great general field where we must do joint battle for our common cause—conservation of our greatest national asset, our men, women, and children. We are at last conceiving a related program, one bringing into full recognition and participation all the lagging and neglected phases of human welfare. There has become a clearly defined recognition of this interrelationship of interests, of the necessity we are under to combine in a program of social action the best which extensive specialization along many lines can give.

We are realizing too that in the advance toward our common objective we must not permit defeats, even temporary, to occur through differences, however sincere, as to methods and means of reaching our goal. Surely we have had ample and painful proof of the way in which forces of reaction which would maintain the old order of privilege, go along together. They do not divide, and too often have "licked" us in the past because it is an outstanding characteristic of progressive, independent minded persons and groups to be sure their own particular way is best. And while we have debated ways and means, those clinging to the *status quo* of privilege for the few as against progress for the many, have crept up on us and circumvented us. Welding together all the varying points of view and the vital contributions that can come from all who have a common purpose into a solid and united front, is a very real challenge and fundamental responsibility we face today—one I think we can honestly say is being met with increasing effectiveness and intelligence. But we cannot slacken in our watchfulness and efforts to move forward with increasing coöperation and understanding. If eternal vigilance is the price of liberty, even more so is it the price of social progress.

We want to see full utilization of all our existing knowledge and tested methods of improving human conditions. We want to push forward, too,

* Read at the First General Session of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

the borders of that knowledge and learn how further conservation of human resources may take place, realizing as we do the needless and tragic wastes that are all about us.

One of the numerous constructive and important steps in this direction is of particular interest to this conference—the National Health Inventory now being conducted by the U. S. Public Health Service as a Works Progress Administration project, under the direction of Dr. L. R. Thompson and George St. J. Perrott of the Service, and made possible, as are so many valuable and lasting pieces of work today, by the tireless interest in and devotion to human welfare on the part of the Works Progress Administrator, Harry Hopkins.

Many of you are familiar with the plan and scope of the survey, but I would like briefly to discuss it here, not only because it needs your full understanding and interest, but also because of its direct bearing on, and contributions to, your own developing plans and responsibilities under the Social Security Act. The survey may be outlined under 5 heads:

1. An inventory of public health and medical facilities throughout the nation.
2. A survey of the extent and nature of disability from illness (including accidents), chronic diseases, and physical impairments, to be made in cities and rural areas in nineteen states. About 700,000 families are to be enumerated through a house-to-house survey in the 19 states. Some 6,000 persons will be employed in this canvass at its peak. The primary purpose of the survey is to secure, for a known population group, information on cases of illness attended by a physician and to obtain accurate statements as to diagnosis.
3. A measurement of the extent to which the health and medical facilities are actually used in different types of communities by persons suffering from various kinds of disabling illness and other physical or mental impairment.
4. The determination of sickness and mortality rates, according to occupation, based on reports of sick benefit associations.
5. A special survey to determine the inci-

dence of the communicable diseases, the frequency of immunizations, and the completeness of reports to health departments.

The scope and methods for the above parts of the whole project are as follows:

1. An inventory of public health and medical facilities supplementing information now available. These health facilities include public health agencies, both official and unofficial; medical facilities, including the distribution of physicians, hospitals, and institutions; and the number and distribution of public health nurses, nurses in private practice, and nurses employed by visiting nurse associations, public and private. All existing information will be utilized, such as the data already published by the American Medical Association, the American Hospital Association, and other agencies including the American Public Health Association. The new data will be collected only where and when it is needed in order to fill up gaps in the knowledge and inventory of health facilities. This phase of the work will be coördinated with the illness survey but will not involve the employment of relief personnel in securing the information.

2. The extent of disability from disease and accident with special relation to chronic conditions and impairments. In this, the coöperation of the medical profession is necessary in order to supplement the enumeration of surveyed populations and of disability by technical information on the nature of disabling illness among those who have been attended by physicians.

Although recent morbidity studies have thrown light on the problem of chronic diseases and physical impairment, the data are not extensive enough or specific enough to give an adequate picture of the situation; hence it is proposed that in the 19 states sample groups of families in different types of communities should be canvassed for this purpose, utilizing carefully selected enumerators under the direction of trained supervisors.

It may be stated as a basic principle of the study that no phase of the project involves a duplication of already existing material. The study is being undertaken because present information, especially that dealing with

chronic disabling illness, is inadequate.

The survey follows closely the well established policy of the Public Health Service and essentially employs methods which have long been used by the Service. It is a continuation of activities which have been carried on for some time—in certain aspects over a period of nearly 20 years.

The goal of the survey is to develop facts that will eventually provide human beings with greater security against the hazards of disabling illness. Modern preventive medicine has made great strides in increasing our security against early death as evidenced by the fact that the expectancy of life has increased from about 40 years in 1870, to 60 years in 1935. This gain has been largely due to the prevention and control of the communicable diseases. It is now proposed to study the causes of chronic illnesses and disabilities which usually appear after middle age and which are so intimately associated with the economic and social status and habits of the people.

The survey provides national recognition of the fact that the health service of the future will probably be expanded to cover other fields than the control and prevention of the communicable diseases. With the coöperation of the medical profession, the control, prevention, and cure of all the ills of the flesh must be the ultimate goal of the health department.

Few of us realize what the presence of a serious or long-standing chronic illness in a household means as to the ability of the family to maintain itself on a self-supporting basis and procure the needed medical care. In fact, we cannot say from our present store of information how many families or individuals are afflicted with some serious chronic disease or impairment which results in partial or complete economic disability.

The survey will undoubtedly reveal

that inadequate medical care is being received by families in the lower income groups and those on relief rolls. These under-privileged families have the greatest need of adequate care because of the high rate of disabling illness and impairment among them. A recent survey made by the Public Health Service in 10 cities showed that the disabling illness rate was 56 per cent higher among families hardest hit by the depression than it was among their more fortunate neighbors, and it showed too that these "new poor" received only about one-half the volume of physician's care that the comfortable group obtained. The discrepancy would have been even greater except for the large volume of free care received by the poor group.

Free service included service free to the family because paid for by state or local government as well as service given free by the physician. It is becoming widely recognized that physicians and hospitals cannot be expected indefinitely to render service to the indigent without remuneration, and that there must be public responsibility for the medical care of these unfortunates who otherwise must depend upon the charity of physicians. The health survey will provide information as to the amount of disabling illness among these people and the volume of medical services now being received, and will give for the first time an accurate picture of the needs both of relief clients and the large group of the "medically indigent" who are able to subsist but unable to finance a serious illness.

It is not necessary to describe to this conference the intimate and immediate effect on public health objectives of a period of economic depression such as we have been going through. Nowhere is sharp curtailment in expenditure more quickly felt in such times than in the public health field. The experience of

cities in 1934 shows that health budgets were reduced on the average about 20 per cent from the experience in 1931, reductions varying from 1 or 2 per cent to as high as 50 per cent. Where this reduction amounted to 30 per cent or more a practically complete breakdown of the public health protective facilities resulted.

On every side you who were daily and hourly in touch with the general widespread want, insecurity, and suffering translated into individual, concrete terms could bear testimony—and did—as to the appalling human deficit which we were piling up. The acute conditions of these recent years have revealed to us, however, how utterly inadequate provisions for health were even in those years glamorously referred to as the time of amazing prosperity.

In that peak year of our American material greatness, 1929, the people of the United States spent \$3,656,000,000 for all forms of medical care, including those services purchased directly through taxes and other community funds. This is approximately \$30 per capita per year, and in 1929 constituted about 4 per cent of the money income of the country. Certainly this expenditure could not be considered excessive for the population as a whole in view of the national expenditures in 1929 for tobacco, toilet articles, and recreation (\$5,807,000,000) or for automobile use and other travel (\$9,475,000,000). The proportion of the medical dollar which was spent for public health in 1929 was 3.3 cents.

Last week in Albany, at the conference on crime called by Governor Lehman, it was reported that our annual national crime bill is 14 billion dollars, about one-fourth the national income.

Other facts as significant and fundamental as these should be foremost in the mind of every one of us. In this

same year of 1929, at the peak of the stockmarket boom, the average per capita income of all salaried employees at work was only \$1,475. Eighteen million gainfully employed persons, constituting 44 per cent of all those gainfully occupied, exclusive of farmers, had annual earnings of less than \$1,000; 28,000,000, or nearly 70 per cent, earnings of less than \$1,500. Many people lived in straitened circumstances at the height of prosperity; a considerable number lived in chronic want. Throughout the 20's, the number of people dependent upon private and public charity steadily increased. At least one-third of all our people, upon reaching old age, are dependent upon others for support. Less than 10 per cent leave an estate upon death sufficiently large to be probated. These are but a few of the facts showing widespread social inequality reported by the President's Cabinet Committee on Economic Security.

By the end of the 1920's this want, dependency, and insecurity had reached a climax; had attained, one might say, such a high visibility that no one could longer be blind to its existence. We were shocked out of our long habit of complacency about ourselves and our general well-being, so much so that the impact of what we saw drove us to what we might call a defense terminology—we called what we saw an "emergency" situation. The millions of hungry, jobless men, the millions of undernourished children, the break-up of countless homes, and the breakdown of morale of countless citizens—we considered things suddenly emerging upon us out of an unpredictable catastrophe. But now, as the crest of the wave which broke over us diminishes and we see everywhere about us the acuteness of human suffering being lessened, as we see signs of conservation and building replacing waste and destruction, we realize more and more keenly

that a callous ignorance of, or indifference to, public affairs on the part of our citizenship was one of the chief factors in our social disaster, and that it cannot be tolerated in a progressive democracy.

So we come to a second important lesson we have learned, or are learning—that to a far greater extent, and with more vigor and alertness than ever before, we must function as citizens in public affairs, as well as specialists in our chosen work. There can be no progress except as it is the progress of all; no security unless there is general security; no enduring prosperity for any small or privileged group except as prosperity on a constantly widening and deepening base is built. Our own aims and dreams of achievement in specialized fields will come true only as we join with minds and hearts in the battle to make our country the thing our forefathers envisioned it to be, a place of equal opportunity to all and special privilege to none.

Twenty-four centuries ago, in another democracy, that of Athens, one of the greatest statesmen, Pericles, voiced a conception of a people's state which closely parallels our own. Above all, he emphasized the utter uselessness to Greece of citizens who did not participate in public life. His words hold much suggestiveness for us today.

With full appreciation of the heavy and unending tasks this challenge calls us to, we can in all honesty feel that we are on the rising trail, that we can look to an immediate future safeguarded, as the present is not, against certain devastating insecurities which individuals in our complex, highly organized state are powerless to cope with. Unless there is social security for the great mass as well as for the few, then our liberty is little less than mockery. We know that we have written into the law of our land the principle that human welfare, hu-

man conservation, is definitely a charge on government, and that in the time to come men and women shall not be broken in spirit and made a social liability because of their advancing years or inability to get work. The terror of dependent old age and involuntary idleness is to be, we have pledged, to some extent at least, lifted from our citizenship.

The youth of today, by whose minds and hearts and hands tomorrow's future will be shaped, we have declared must not have their most impressionable and important years dominated by inadequacies both physical and spiritual. Nine million children knowing only relief homes have made up 40 per cent of the total relief load these recent years. They have not been having the sort of chance we pride ourselves all American children are entitled to. So we have, as an organized society, pledged ourselves to ways and means by which their fathers may have guarantees of their right to participate, through free organization, in our industrial development, guarantees that decent wages and working conditions may reestablish the American home. We have taken our stand against the needless and preventable loss of life and health costing now in money terms some 2½ billions a year. We have outlined and ratified, as a people, measures to overcome these wastes and to establish through national, state, and local coöperation, policies of conservation in their stead.

We are "on our way"—forward; but the knowledge that we are, must serve only to make us more vigilant to safeguard gains which have been made, and more aggressively determined to continue our advance against waste and special privilege, and to stand up to be counted among the forces seeking to conserve human life and human happiness.

The Social Security Act in Its Relation to Public Health*

C. E. WALLER, M.D., F.A.P.H.A.

Assistant Surgeon General, United States Public Health Service, Washington, D. C.

IN an address made during the early part of his present term, President Roosevelt, in discussing his program for economic recovery, said: "Among our objectives I place the security of the men, women, and children of the Nation first." With a view to devising a sound plan for a program directed toward this objective the President later appointed the Committee on Economic Security to study the social and economic conditions which affect individual security. The Economic Security Bill, which eventually was enacted into law as the Social Security Act, was based upon the recommendations of this committee formulated in the course of its studies over a period of several months.

The general title of the Social Security Act approved by the President on August 14, 1935, sets forth the purpose of the Act as follows:

To provide for the general welfare by establishing a system of federal old-age benefits, and by enabling the several states to make more adequate provision for aged persons, dependent and crippled children, maternal and child welfare, public health, and the administration of their unemployment compensation laws; to establish a Social Security Board; to raise revenue; and for other purposes.

Specifically the Act provides for federal old-age benefits; for grants to the states for old-age assistance, unemploy-

ment compensation administration, aid to dependent children, aid to the blind, and maternal and child welfare; and for public health work, including the authorization of grants to states for aid in the development and maintenance of state and local health services and an annual appropriation to the Public Health Service for additional research activities.

Grants to the states authorized for maternal and child welfare include assistance in the maintenance of maternal and child health services, care of crippled children, child welfare services, and vocational rehabilitation.

For the administration of grants-in-aid features of the Act relating to old-age assistance, unemployment compensation, and aid to dependent children and the blind, the Act created a Social Security Board. The Children's Bureau of the Department of Labor is charged with responsibility for administration of grants for maternal and child health services, care of crippled children, and child welfare services; the Office of Education of the Department of Interior will deal with federal aid for vocational rehabilitation, and the Public Health Service will administer the grants to states for aid in establishing and maintaining state and local health services.

It is to be assumed that every feature of the Social Security Act will have some relation, either directly or indirectly, to the public health. Certainly the greater feeling of economic security

* Read before a Special Session under the auspices of the Health Officers Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

to be experienced by the wage earner and the individual looking forward to old age should contribute in some measure to better mental health; and it seems reasonable to believe that relief from want and deprivation in childhood and in the time of unemployment should lessen, to some extent at least, the hazards of disease resulting from lack of proper nutrition and the lack of means of providing at least some medical care. However, I take it that you are interested at this time chiefly in the provisions of the Act that deal specifically with health activities.

Under the Public Health Work Title of the Act authority is granted for:

1. An annual appropriation of not to exceed \$8,000,000 for the purpose of assisting states, counties, and health districts and other political subdivisions of the states in the establishment and maintenance of adequate health services, including the training of personnel for state and local health work.

2. An annual appropriation of not to exceed \$2,000,000 to the Public Health Service for research activities of the Service and for the expense of coöperation with the states in the administration of the federal funds to be granted for aid in the establishment and maintenance of state and local health services.

' Responsibility for allotment of the proposed appropriation of \$8,000,000 for state and local health services is placed upon the Surgeon General of the Public Health Service. In making the allotments to the states, however, the Surgeon General must take into account certain major factors; namely, the relationship of the population of each state to the total population of the United States as a whole; the financial needs of certain states, or the inability of the states to meet their health problems without financial assistance; and special health problems imposing unusual burdens upon certain states. The weighting and application of these factors in the distribution of the fund will be in the discretion of the Surgeon General, subject to the approval of the

Secretary of the Treasury. It should be noted particularly that the allotments are to be made to the states and that the Public Health Service cannot deal with local authorities either in the distribution of the fund or in the consideration of plans for the work.

The entire appropriation for aid to states each year must be allotted at the beginning of the federal fiscal year. However, the fact that an allotment has been made to each state will not necessarily mean that each state actually will receive the full amount of its *allotment*. The Act provides that *payments* to the states from allotments shall be determined by the Surgeon General, subject to approval by the Secretary of the Treasury, in accordance with regulations previously prescribed by the Surgeon General after consultation with a conference of the State and Territorial Health Authorities. Once funds have been allotted and paid to any state, they must be expended solely for the establishment and maintenance of health services and in accordance with plans presented by the health authority of such state and approved by the Surgeon General.

In anticipation of the enactment of the Social Security Act before the close of the latest session of the Congress, the Surgeon General laid before the Annual Conference of State and Territorial Health Officers with the Public Health Service held in Washington on June 17, 18, and 19, a suggested program which might serve as a basis for regulations to be promulgated by the Surgeon General governing the conditions under which payments from allotments would be made to the states. This program, with some modification in respect of details, was approved by the Conference and recommended to the Surgeon General for adoption.

With respect to general objectives of the program and plans for organization of the work to be carried out by the

states with the financial aid expected under the provisions of the Social Security Act, the report approved by the Conference of State and Territorial Health Officers contained in part the following recommendations:

It is the aim of the Economic Security Act, among other purposes, to stimulate a comprehensive, nation-wide program of public health, financially and technically aided by the federal government, but supported, so far as possible, and administered by states and local communities.

The \$8,000,000 annually appropriated for aid to states will be available for the following purposes:

1. Aid to state and territorial health departments for strengthening the service divisions and in providing adequate facilities especially for the promotion and administrative guidance of full-time city, county, and district health service.

2. Aid through state and territorial health departments for the development of city, county, and district health departments.

3. Training of public health personnel.

However, no state or territory should be eligible for aid unless and until it shall have provided or provides in its proposed plan for certain essentials of health organization hereinafter set forth.

Grants in aid to existing state or local projects should be supplemental to funds now being expended, and in no case should be used to replace existing state or local appropriations to such projects for the purpose of relieving state or local authorities from expenditures now being made.

Although it is recognized that many state and territorial health departments conduct a number of important specialized activities, for the purpose of allocation of funds under this Act, no state or territorial health department should be regarded as properly organized which does not provide as a minimum on a full-time basis the services listed below:

- a. A qualified full-time state or territorial health officer.
- b. Adequate provision for the administrative guidance of local health services.
- c. An acceptable vital statistics service. This should include an approved plan for the registration of births and deaths and the prompt forwarding of information relative thereto to the Public Health Service.
- d. An acceptable state public health laboratory service.
- e. Adequate services for study, promotion,

and supervision of maternal and child health.

- f. Special services for the study, promotion and guidance of local activities for the control of preventable diseases and for health promotion. This should include an approved plan for the collection of reports of notifiable diseases and the prompt forwarding of information relative thereto to the Public Health Service.

- g. Services for study, promotion and supervision of environmental sanitation.

Provided: that exceptions to this requirement may be made where it shall be determined by the Surgeon General that one or more of these services are uneconomical or unprofitable in a given state.

Existing deficiencies in minimum essentials of organization at least temporarily may be supplied through coöperative budgets developed with the use of allocated funds, provided that the amount used in such development of essential services does not exceed 20 per cent of the funds available from federal sources to be allocated to such state or territory. Provided, further, that funds allocated by the Public Health Service may be used in the building up of these essential services beyond the point of minimum requirements, particularly for the stimulation and supervision of local health service in accordance with the provisions hereinafter set forth and acceptable to the Public Health Service.

Subject to these requirements, the U. S. Public Health Service should consider expenditures proposed by a state for any health activity on which the state health agency now expends state funds or is authorized by law to expend such funds; the U. S. Public Health Service should reserve the right, however, to disapprove any proposed project or to decrease any item of proposed expenditure if in its opinion the purposes of the Act would be better attained thereby.

The basis of a satisfactory local health service is a well organized health department, adequately financed, with trained personnel, supported by suitable laws and ordinances, by favorable public opinion, and by all professional groups. To this end financial aid is to be granted, through the state and territorial health departments, toward the development and maintenance of adequate city, county, and district health organizations.

Allotments of funds should be made toward the establishment or maintenance of city, county, or district health services only when the following basic principles of organization and services in a community are met:

1. The public health services of the city, county, or district shall be under the direction of a whole-time health officer.

2. The personnel of the city, county, or district health department should include, in addition to the full-time health officer, such medical assistants, public health nurses, sanitation officers, and clerks as will insure at least a minimum of effective health service commensurate with the population and health problems of the area concerned.

The U. S. Public Health Service in its allocation to states should strive to foster the development of health units having a minimum personnel of one full-time health officer, two nurses, one sanitary officer and one clerk. When a district health unit comprises more than one county or parts of counties there should be at least one public health nurse and one clerk for each county or similar political unit of government embraced in the health district. In areas whose economic status does not justify this desired minimum the U. S. Public Health Service may feel free to modify these standards.

Personnel inclusive of health officers, nurses, sanitation officers, sanitary engineers, and other public health personnel employed under these grants-in-aid should meet the standards of qualifications established and recommended by the Conference of State and Territorial Health Officers.

The success of the Economic Security Act in the field of public health will depend upon the availability and employment of competent and professionally trained personnel. It is therefore recommended that funds be allocated to the states to assist in developing trained personnel for positions to be established for the extension of state, city, county, and district health organizations, and that minimum qualification standards for the necessary personnel be adopted by the Conference of State and Territorial Health Officers to serve as one of the conditions upon which the federal funds provided in this Act shall be allocated to the states for state and local health services.

The Conference at the same time prepared and recommended a standard of technical qualifications for public health personnel; recommended the setting aside of a special sum to be distributed among the states for the training of personnel as a part of the allotment to each state; suggested a procedure for the establishment of regional training centers for short courses to meet im-

mediate personnel needs; and set up a committee to consider and prepare standard record systems and report forms for the use of state and local health authorities.

In formulating qualification standards a special committee of the Conference followed closely the report of the Committee on Professional Education of the American Public Health Association.

In preparation for carrying out the provisions of the Public Health Title of the Act when the first appropriation becomes available, the Public Health Service has drafted and submitted to the Secretary of the Treasury for approval proposed regulations governing the allotments and payments to be made to the states. It is anticipated that these regulations will be passed upon by the Secretary within a few days. While they cannot, for obvious reasons, be discussed in detail at this time, it may be said that the draft submitted to the Secretary is substantially in conformity with the recommendations of the Conference of State and Territorial Health Officers so far as general policies may be concerned. In brief, these proposed regulations set up the amounts of the state aid appropriation to be set aside for allotment on the basis of population, financial need, and special health problems, respectively, through the weighting and application of these factors; provide for the matching of certain portions of the allotments with existing and new state or local appropriations as a condition upon which payments from allotments shall be made; require the submission of plans to be approved by the Surgeon General prior to the certification of the payments; require the submission of budgets to show the extent of state or local participation in support of the work; and call for periodic financial and statistical reports to show the expendi-

tures made from all sources as well as a brief summary of the progress of the work.

While the Public Health Service, realizing the desirability of preserving the independence of the states in matters affecting public health wholly within their boundaries, will not lay down rigid requirements with respect to either organization or qualifications of personnel, it will require that the general plan submitted by each state shall provide for efficient administration and sound expenditure of the funds. The Public Health Service will also recommend to the several states the plans of organization for state and local health services and the standards of qualifications of personnel recommended by the Conference of State and Territorial Health Officers.

THE TRAINING OF PUBLIC HEALTH PERSONNEL UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

Manifestly if public health work is to meet successfully the constantly changing demands there must be, first of all, aims and objectives that are practical, reasonably susceptible of achievement, and productive of results. Moreover, there must be a willingness to adjust principles to meet the newer conceptions of what is required. Obviously it is upon the public health worker, whether he be the state or local health officer or other member of the staff, that the burden of successful effort rests.

There has been a great deal of undesirable and unnecessary unrest among the personnel of health departments. In many organizations, whether state or local, there have been disturbing changes of personnel. In some instances, due to political expediency, competent workers have been unceremoniously dismissed while incompetent individuals have been retained. Only too often the funds for the maintenance of

efficient health services have been curtailed or withdrawn as the first rather than the final step in an economy program. Needless to say, such interference with plans and personnel has created an impression that public health work is a semi-permanent activity of dubious value that may be turned off and on like a controlled stream of water. The time is now at hand for removing permanently the hindrance to an enlightened and progressive public health viewpoint. In no way can this be better done than by assuring adequate salaries, undisturbed tenure of office for competent persons, and sufficient training to insure efficient service. The belief may be expressed that when public health workers become proficient in their professions through proper academic and practical training that commensurate salaries and prolonged tenure of office will follow as a matter of course. A health department should be an integral part of the local government, on an equal footing with school, justice, and police administrations. The opportunity offered for the training of public health personnel under the provisions of the Social Security Act will undoubtedly aid in attaining the objectives just mentioned.

Public health work should be a profession, as clearly defined as that of law, medicine, engineering, pedagogy, or other specialties. Moreover, a public health career should be as attractive, lucrative, and permanent as any other professional field. While the opportunities for financial advancement may not be as promising as elsewhere, there is always the prospect of affording service to humanity, through the prevention of unnecessary illness and premature death.

Recognizing that the training of public health personnel is a pivot around which the health provisions of the Social Security Act revolves, the Conference of State and Territorial Health

Officers, which met with the Public Health Service in June, 1935, devoted a goodly share of its attention to this phase of the subject.

The Conference recommended that \$1,200,000, or 15 per cent of the proposed \$8,000,000 annual appropriation, be set aside for the prompt development of qualified personnel designed to strengthen and enlarge the staffs of state and local health departments. In furthering these objectives it was recommended that the Public Health Service proceed to develop suitable training centers at existing institutions, conveniently located to serve certain groups of states, and that the cost of aiding these institutions where necessary be prorated among the states to be served by the proposed centers. Furthermore, it was suggested that funds be granted to the several state departments of health in accordance with their needs, as certified by the state health officers, for the purpose of paying living stipends, tuition, and traveling expenses of trainees who would be selected by the state health officers for attendance upon courses to be given at the training centers.

It is desired to emphasize that selections of public health trainees are to be made by state departments of health and not by the Public Health Service. Moreover, it is expected that positions will be provided in state and local health departments for those who have satisfactorily completed the course of training. Therefore, it is essential that the nominations of trainees be correlated with the plans and financial resources of each of the state departments of health.

So far as may be practicable it is the intention to utilize existing public health training centers. However, when necessary, the establishment of new facilities for public health training in existing institutions will be encouraged. It is planned to establish

training facilities as they may be needed to meet the demand created by the state departments of health, *i.e.*, the number and kind of trainees will be determined by the state departments of health, and the facilities will be adjusted to the demand for service. In the beginning attention will be given chiefly to the development of facilities for short courses to meet the emergency need.

Provision will also be made for a center in which Negro nurses may secure public health training. While the location and facilities to be provided will depend upon the number of nurses nominated for training, it is expected that a number of state departments of health, especially those having large Negro populations, will take advantage of this opportunity.

To provide for additional field training after instruction at the training center has been completed, funds will be available for augmenting the staff of a local health unit selected by the health officer in each state to serve as a field demonstration station.

The rather sudden and rapid expansion of public health work contemplated under the provisions of the Social Security Act will create an immediate demand for considerably more personnel than is at present available. Therefore, it becomes necessary to consider the length and content of training courses that should be offered. Many of the established schools of public health feel that their paramount duty is toward students taking regular and full courses of instruction. However, in view of the necessity for training a considerable number of workers within a comparatively short space of time the establishment of short courses has received considerable attention. In general it is believed that 2 months of systematic instruction should be regarded as a minimum. An additional month of apprenticeship under a well

trained and experienced health officer, preferably in the state in which the trainee expects to work, should be provided. It should be possible for a student taking a short course to receive credit which can be utilized in securing a certificate or degree when further instruction is taken.

While there may be some difference of opinion regarding the content of short courses for health officers it is believed that biostatistics, epidemiology, environmental sanitation, and administration should be emphasized. In schools serving southern states medical zoölogy should be included. In setting up training schools for nurses the institutions meeting certain requirements in regard to theoretical and practical instruction, according to the standards of the National Organization for Public Health Nursing, will be favored. Courses for sanitarians of the different grades will be organized along the same general lines, the course being worked out on the basis of experience. However, all trainees of whatever grade, will be expected to be well grounded in the principles of public health administration.

Another possibility in connection with the training of public health personnel is that of supplying instruction to persons already employed. Through this policy older employees would be enabled to secure new and up-to-date information as to public health procedures and thereby increase their personal efficiency and value to the organization in which they are employed. It may also be possible to use trainee reserves in local health units while regular employees are attending special short courses.

The prospect of strengthening state and local health administration through the medium of allotments from the Social Security appropriation is an alluring one. By no means the least important contribution to the public

health forces will come through the training of personnel.

SIGNIFICANCE OF PUBLIC HEALTH LEGISLATION IN THE SOCIAL SECURITY ACT

It is evident that the Congress, in considering this legislation, deemed it within the intent of what is known as the "welfare clause" in Paragraph 26, Section VIII, Article I, of the federal Constitution. In this respect the Public Health Title of the Social Security Act differs from most of the existing law relating to the functions of the Public Health Service, which has for its authority the power granted by the Constitution to the Congress to regulate commerce. This is regarded as being particularly worthy of note. For the first time in the history of the public health movement in this country, the Congress has made a declaration of permanent policy under which it assumes in part responsibility for protection of the health of the individual within the state and has made provision for participation of the federal government in the establishment and maintenance of administrative health services for this purpose. The significance of the authorization of an appropriation of \$11,800,000 for aid to the states for health services therefore lies not so much in the amount of federal aid provided for as in the effect of this enunciation of federal policy. It is obvious to everyone that \$11,000,000 or \$12,000,000 granted to the states by the federal government will not alone go very far toward meeting the need for more adequate local health service in this country; we need at least one dollar per capita, per year, or \$126,000,000 from all sources, to provide even the minimum of service required, and more for adequate service. The most important result of the Social Security Act in the field of public health should be the awakening of state and

local authorities all over the country to the need for devoting more attention to the public health and the stimulation of such authorities to the assumption of greater responsibility in making provision for adequate facilities for health protection.

With the exception of that part of the law dealing with crippled children, and possibly the provisions authorizing aid to states for maternal and child health services, the Social Security Act leaves one of our important public health problems as yet among the social security problems in the solution of which no substantial steps have been taken—the problem of medical care for the poor and for the low-income family that can pay something but not the whole cost of medical and hospital service which it requires.

THE MEDICAL CARE PROBLEM

I find myself personally unable to hold with some others to the doctrine that the working out of some solution of this problem is not a part of the public health problem. I have been unable to see the soundness of the distinction some of us have maintained between what we have called “public health work” and responsibility for seeing that adequate medical care is provided for those who cannot afford it. Nor can I see any good reason for assuming that the term “public health” should apply only to preventive measures.

Fifty years ago most of our mortality was caused by the acute communicable diseases; it was but natural, therefore, that our early activities in the protection of the public health were centered largely on the control of communicable illness. But the picture has changed and today we find our problems more and more in the prevention of disability and death from diseases that will not yield to environmental sanitation and immunization. I

venture to predict that the most important activity of the health department of the future will lie in the medical care field, at least in assumption of responsibility for meeting the problem and of leadership in working out the solution.

I am not prepared to advocate at this time that the health department shall actually undertake to render with its own personnel all medical care for the poor. I feel that there is and should be a place for the practising physician in a medical relief program wherever economic limitations will permit the utilization of his services. On the other hand, the provision of adequate medical care for the poor is a public duty, and the private physician can no longer be expected to carry the burden without adequate compensation. But I do not believe we shall have a satisfactory solution of the problem until the health department takes the leadership in working out with the medical profession a plan that will serve the need and at the same time make a place for the services of the private doctor. There can be no doubt of the need for more medical service, nor of the existence of a vast reservoir of potential service not now utilized; what we lack is the mechanism for putting this service to work.

THE RESPONSIBILITY OF STATE AND LOCAL AUTHORITIES

In conclusion, I should like to give special emphasis to just one point that may not be clear in connection with the provisions of the Social Security Act authorizing grants to states for public health work. The Act does not appropriate the funds—it simply authorizes the Congress to appropriate in any one year amounts *not to exceed* the sums set forth in the Act. Therefore the Congress is not bound to appropriate the amounts authorized and may appropriate so much or so little,

within the limitations of the Act, as it chooses to make available. There can be no doubt that in determining from year to year what the appropriations shall be, the Congress will be influenced by evidence of efficient administration and accomplishment or by the lack of it. We shall all be on trial. If our accomplishment should justify it, there is a possibility that the federal government may even increase its participation in the future; if we should fail, we shall not even hold the appropriations now authorized.

In passing on to the states the responsibility for organization of the work and for qualifications of personnel,

in the interest of preserving their independence, the Public Health Service rightly places largely upon them the responsibility for accomplishment and for the demonstration to the Congress that the grants from the federal government are being wisely expended. May I, therefore, urge those of you who will participate in the administration of these funds to see that the highest standards of professional service are maintained, that appointments are not made solely because of political considerations or personal friendship, and that no dollar is wasted. After all, the appropriations will be yours, and likewise the responsibility for preserving them.

Nutrition and Child Health*

A. B. SCHWARTZ, M.D.

Department of Pediatrics, Marquette University Medical School, Milwaukee, Wis.

AS far as the infant is concerned, there may be justification for the idea that nutrition has to do only with foods and food disturbances. Beyond infancy, such a conception of nutrition has neither physiologic basis nor practical usefulness. The White House Conference Report defines nutrition as "a study of the food substances and of the biochemical processes which utilize them." "Good nutrition," continues the Conference Report, "should mean that these biochemical processes are proceeding correctly."

When we speak of good nutrition we imply good health. In order for biochemical processes to function normally, it is necessary that every tissue in the body that has to do with these biochemical processes must function

normally. The teeth must be normal, and so must the saliva, the stomach and its juices must be normal, the heart and lungs, the excretory organs, and the nervous system must be normal. It is equally obvious that brief upsets of any of these and other structures may not recognizably upset nutrition.

Nutrition problems as seen in public health work are problems related to general health and are influenced by factors often remote from physiology alone. They are in fact problems of biology, psychology, and sociology.

Is there a way of measuring nutrition?

The idea of weight as a criterion of health is fallacious. Height and weight tables, despite much scientific protest, continue to play too large a part in child health work. It is reported that the largest return on any investment in the Century of Progress Exposition was that from the "Guess

* Abstract of paper read at a Joint Session of the Child Hygiene and Food and Nutrition Sections of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

Your Weight" scales, and an editorial writer in the *Journal of the American Medical Association* remarks that "normal weight does not necessarily mean good health, nor do deviations from the average or mean always indicate poor health." Physiologic objections to the weight-height table as a measure of good or had nutrition do not need to be restated. Blackfan in his "Approach to the Subject" in the White House Conference publication on Nutrition makes the pointed comment, "The distinction between an activity of processes and the physical state which they produce justifies disregarding the static and dimensional criteria of growth and development."

The nutritional state as popularly measured by the height-weight relationship has attained an undue importance in the parents' mind and in our own daily work. It is high time that we began to teach that we do not measure health with a pair of scales. It is not important to know whether the weight and height of the particular child coincides with the average weight and height of a thousand other children. What is important to know is whether the weight and height of this child is within the limits of health for this individual child.

Weight and height tables of whatever kind, or the recently devised ACH index of Franzen and Palmer are useful as screening methods, roughly selecting those that need further examination. Represented as such, the ACH index seems the more selective method for large groups of children.

A good physical examination is a basic necessity in the study of child health. This, too, is not enough. Personal observation of the child in the home, a knowledge of his environment, an understanding of his attitudes in school and at play are all necessary in the appraisal of the child's health.

It is high time that we begin examining children and distributing information with a conscious realization of individual variations. Equally important as individualized physical examination is the need for individualized instructions by child welfare workers.

If we are going to do nutrition work among children, let us see to it that we do it with a proper understanding that the child's nutrition problems are not only problems of vitamins and mineral salts but also problems of psychology and sociology. Enough people should be trained in child health, in home nursing and in social service to provide a more adequate service. The children of families able to pay for such service should be referred to their private physicians. The welfare station that takes care of this group of children is not only wasting community funds, but cluttering up its own work, and thereby giving less efficient service to those who do need it.

Much waste of a family's income could be eliminated by a proper attention to this problem in a nutrition clinic.

Useless vitaminizing should be part of the child health clinic's concern. The importance of the respective vitamins in child health needs no restatement. Their discovery and application constitute one of the most thrilling chapters in medicine. Eventually, their isolation as crystalline substances will further increase our understanding of their usefulness. Each vitamin has a recognized value sufficiently established to make it an essential implement in any health program. This does not make necessary the indiscriminate prescription of vitamins for conditions in which their usefulness is still in the speculative zone.

Vitamins are important but they are not the whole story. A diet list will not relieve all the defects of nutrition.

Engineering Control of Occupational Diseases*

J. J. BLOOMFIELD, F.A.P.H.A.

Sanitary Engineer, United States Public Health Service, Washington, D. C.

THE control of occupational diseases lies chiefly within the sphere of two types of workers, the physician and the engineer. It is within the province of the physician to diagnose occupational diseases and primarily to recognize the existence of those diseases due to the factory environment. Based on the findings of the physician, the engineer is in a position to learn where control measures are to be initiated. His functions are two-fold: First, he must study the local plant conditions which have been shown to be detrimental to health and by precise quantitative measurements determine the extent of the hazard. Second, once the nature and degree of the hazard have been demonstrated, the engineer must consider ways and means for controlling or minimizing the dangerous condition and for studying the effectiveness of these measures.

It is the purpose of the present contribution to discuss the various engineering methods which may be applied in the evaluation and control of industrial health hazards.

THE STUDY OF THE WORKROOM ENVIRONMENT

Certain preliminary steps of fundamental importance must be undertaken

in order to serve as a guide in the more detailed studies which may be indicated. These consist of the sanitary survey and the occupational analysis of the workroom.¹

The sanitary survey of a workroom consists of noting provisions for ventilation, illumination, fire protection, accident protection, exposure to specific poisons, such as dusts, fumes, vapors, and gases, fatigue, and so on. Thus, the survey serves as a guide in establishing which hazards require further study in the form of actual quantitative determinations.

The occupational analysis permits one to learn of the activities involved and the particular hazards associated with each occupation, and the number of persons in each occupation. Perhaps a typical illustration from actual experience will demonstrate the value of the preliminary survey of an industrial establishment.

Studies of industrial morbidity among iron and steel workers conducted by this office showed that pneumonia, in all forms, occurred in nearly twice the number among these workers that it did among employees of other industries, during a 3 year period of observation.² A 5 year inquiry into the causes of high pneumonia rates among iron and steel workers in a representative mill disclosed the fact that the largest number of cases occurred in certain departments, such as in the blast furnace and

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935.

TABLE I

FREQUENCY OF PNEUMONIA ACCORDING TO OCCUPATION AND IN RELATION TO THE NATURE OF INDUSTRIAL EXPOSURE INVOLVED IN THE BLAST-FURNACE DEPARTMENT, 1924-1928

Sections and Occupations	Nature and Extent of Industrial Exposure ¹					Annual Number of Cases of Pneumonia per 1,000 Men	Number of Cases of Pneumonia		Approximate Number of Years of Life Observed
	Heat With Wide Changes in Temperature	Strenuous Work	Out-door Work in All Kinds of Weather	Gases and Smoke	Dust		Actual	Expected ²

¹ Symbols for extent of exposure:

0 No exposure

* Slight or occasional exposure

** Heavy exposure

² Number expected from the rate per 1,000 men in "all other departments" in Table VII.³ Eight per cent of the men heavily exposed, 23 per cent slightly or occasionally exposed to heat with wide temperature changes. To strenuous work, no one was heavily exposed and only 5 per cent had occasionally to work strenuously. To outdoor work in all kinds of weather, about 8 per cent of the men were heavily exposed, 80 per cent slightly or occasionally exposed. To gases and smoke, about 5 per cent were heavily and 25 per cent slightly or occasionally exposed. About 1 per cent of the men were heavily exposed to dust and about 55 per cent slightly or occasionally exposed.

open-hearth steel mills. When one realizes, however, that these departments contain anywhere from 60 to 100 different occupations, the task of a preventive program is almost a hopeless one, unless definite information is obtained concerning such important items as (1) the number of persons, (2) the activities, (3) the health hazards, and (4) the incidence of pneumonia for each occupation. Such information is available from a preliminary sanitary and occupational survey.

For example, in the study mentioned, it was found that the most important exposures associated with the various occupations were: heat, with wide changes in temperature, gases (sulphur dioxide, hydrogen sulphide and carbon monoxide), dusts, strenuous work, and outdoor labor in all kinds of weather. Table I presents the frequency of pneumonia according to occupation in the blast furnace department, in relation to the nature of the exposures, during

the period of 1924-1928. It is quite obvious that the highest pneumonia rates occurred among those occupations exposed to one or more of the potential hazards cited. The actual number of cases for those occupations not associated with these five exposures (all other sections) was found to be even less than the expected cases of pneumonia for such workers. Such a preliminary survey indicated that, in the blast furnace department, attention should be centered on occupations in the casting and general labor sections, in an effort to determine the degree of exposure to gases, dusts, extreme temperature changes, and so on. Such studies are carried out by the engineer, whose task it is to determine the extent of the occupational exposure to the materials and conditions enumerated. Once these factors have been evaluated, the engineer is in a better position to initiate control measures for the minimization of the hazards demonstrated to be deleterious to health.

The magnitude of the problem confronting the engineer in industrial hygiene is as large as it is varied. According to a recent analysis made by Dublin and Vane,³ there are some 94 groups of industrial poisons in the United States, associated with about 900 different occupations. In the limited space allotted for the present discussion it will only be possible to point out a few of the major problems in this field with which the engineer is concerned.

The subject of the health of workers in dusty trades has been receiving considerable attention from students of industrial hygiene and others interested in the various phases of this problem. When one realizes that the workmen employed in the dusty trades comprise the largest group exposed to any one industrial hazard it is quite apparent that the importance of this problem has not been overestimated. Furthermore, it is by now fairly well established that exposure to certain kinds of dust has increased the mortality rate from respiratory diseases.

As a result of the studies conducted

by this office and other agencies, it has been fairly well established that a knowledge of the properties of a given dust which determine its capacity to produce pulmonary pathology is essential. Numerous investigations of the industrial dust problem indicate that these properties are the chemical and mineralogical composition of the dust, its concentration in the industrial atmosphere, and its particle-size. It is within the province of the engineer to determine these factors in the industrial dust problem. How important these determinations are in such studies is well exemplified by the results of our recent investigation made among anthracite coal miners.⁴

In this particular investigation it was found that the various mine and surface workers were exposed not only to different concentrations of dust but also to dusts of varying composition. For this reason, in the present discussion, data will be given for a group of workers inhaling a dust of the same composition. For example, the engineering study disclosed that workers in the mine haulageways were exposed

FIGURE I

not only to the dust arising from both coal and rock working operations but also to the sand dust used on the rails to obtain traction. A study of the composition of this dust showed it to have a total silica content of 34 per cent, a quartz content of 13 per cent, with 58 per cent of the dust consisting of coal. Due to the relatively low dust concentrations in the haulageways, the mine operators did not suspect a health hazard among the men employed in the gangways.

Figure I shows the percentage of men having anthraco-silicosis under different average dust concentrations and number of years' exposure to such concentrations. When the duration of employment or exposure was less than 25 years, only a negligible proportion of the men developed anthraco-silicosis. There were, in fact, only 3 cases among the 408 men examined whose length of employment was less than 25 years, a percentage of less than 1 for this group as a whole. When the exposure exceeded 25 years, about one-fourth of the men were found to have anthraco-silicosis. The curve of cases mounted rapidly from an exposure of 10 to 20 million dust particles per cu. ft. of air to 80 million particles, at which exposure about one-third of the men were found to have this disease. It is of interest to note that the curve of cases declined slightly under higher dust exposures. Although one cannot state definitely the reason for this tendency, it may be due to the factor of selection.

This single example concerning one of the important problems in industry illustrates the rôle played by the engineer in the field of industrial hygiene. In the present case not only was the study of the degree and nature of the dust exposure valuable in determining the cause and extent of the hazard, but it served as an aid to the solution of the problem; namely, the removal of the dust to a level indicated as safe by

the results of the investigation. The graph also shows the approximate threshold dosage, which may be set tentatively at 10 to 15 million particles per cu. ft. for this type of dust. Only 4 cases of anthraco-silicosis were found among the men exposed to 10-20 million particles and none was found at an exposure of less than 10 million particles. With such information, the engineer is in a position to consider ways and means for the suppression of the dust in the haulageways to the concentration which is indicated as safe.

In the studies of occupational diseases due to the inhalation of certain toxic dusts, such as lead and radium, the engineer has also played an invaluable rôle. In a recent study of lead poisoning among storage battery workers, conducted by the Public Health Service,⁵ it was of importance to determine the relationship between the amount of lead dust inhaled by the men and the incidence and severity of plumbism. Such a study is valuable in that it may indicate the maximum amount of lead which may be inhaled with impunity. Table II shows the fundamental correlation between the lead in the air and the rate of plumbism in the major departments of the plant in which our study was made.

TABLE II

LEAD EXPOSURE AND MAXIMUM MONTHLY RATE OF INITIAL COMPENSATION CASES FOR PLUMBISM

Department	Mg. of Lead per 10 cu. m. of Air	Maximum Monthly Rate (per 100)
Mixing	120.0	44.0
Pasting	50.0	12.0
Burning	5.7	4.4
Casting	1.2	0.18

It is evident that a close correlation exists between the lead exposure in different departments and the risk of developing a case of lead poisoning. Of considerable interest is the fact that a more detailed analysis of the clinical and dust findings indicated that 1.5 mg. of lead dust per 10 cu. m. of air, except for prolonged exposure, is the

limit of safety under the conditions encountered in this study. This important finding is of great value to the engineer, since it gives him a basis upon which to develop protective devices in the way of exhaust ventilation, respiratory protection, and so on.

Utilizing the same technic employed in the study of the dust problem, the writer conducted a study in 1928 on the health hazards associated with chromium plating.⁶ A study of the amount of chromic acid inhaled by these workers, along with physical examinations, showed that ulceration and perforation of the nasal septum was usually associated with an exposure in excess of 1 mg. of chromic acid in 10 cu. m. of air. These results are shown in detail in Table III. It is observed that a fairly good correlation was found to exist between the intensity of exposure to chromic acid mist and the amount of damage to the nasal mucosa,

that part of the respiratory tract usually affected by such exposure. As a result of this finding, it was possible to design chromium plating tanks provided with a certain type and degree of exhaust ventilation, which keeps the air at the worker's breathing level less than 1 mg. in 10 cu. m. and perhaps completely free from chromic acid. In a later portion of this discussion it will be shown exactly how this control problem was handled.

Studies of the industrial environment of the type indicated may be said to serve a three-fold purpose: First, they enable one to determine the extent of the hazard. This is accomplished by ascertaining occupational exposures to toxic materials or conditions. Second, if clinical studies are made, the findings may indicate the permissible amounts of toxic materials tolerated with safety. Third, quantitative studies of the work-room environment are valuable in the

control of a hazard. This is performed by testing the efficiency of any devices which may have been introduced for the minimization of the hazard.

In closing this portion of the discussion it is well to point out that the engineering problems in industrial hygiene will increase in number in the very near future. New processes and chemicals are constantly coming into use and many well known toxic substances are finding new applications in industry. Our knowledge of the action of these substances on the body is being augmented by the work of toxicologists and by field studies of the type presented in this paper.

THE CONTROL OF INDUSTRIAL HEALTH HAZARDS

No set rules may be established for mechanical protection to control an industrial poison. Specific conditions will determine the type of protection. In general, there are 5 methods which may be attempted: (1) substitution of a non-toxic material, (2) isolation of the harmful process, (3) wet methods, in the case of some dusty processes, (4) exhaust ventilation, and (5) respiratory protection.

One example of the substitution of a non-toxic material is the possible use of metallic or other type of artificial abrasive for sand, in the sandblasting process, in operations in which it is not essential to use sand (a substance high in quartz content).⁷ An excellent illustration of isolation is the mechanical enclosure of a dust-creating process by the modern sandblast barrel used in the cleaning of small objects. It is apparent from Table IV that a tremendous reduction in dust has been effected by the substitution of wet for dry methods in the case of both drilling and rock loading.

In most dusty processes, however, the most effective means of dust elimination are by the use of properly de-

TABLE IV
CONTRASTING "WET" AND "DRY" METHODS OF
ROCK DRILLING AND LOADING

Loading	10	636	32

signed exhaust ventilation systems. Since in many instances it is a difficult, costly, and at times unnecessary procedure to remove all the dust in the vicinity of a worker, it would be helpful to determine the minimum amount of a certain dust which the worker can apparently tolerate with impunity. Such information can be made available by the type of studies carried out by the Public Health Service (already mentioned).

For example, in the anthracite coal study,⁴ it was found that miners exposed to less than 50 million particles of coal dust per cu. ft., with less than 5 per cent quartz in the dust, apparently suffered no disability even after many years of work. In the case of workers in haulageways, who were shown to be inhaling a dust with a higher silica content, the safe limit was placed at 10-15 million particles. In certain of the mines under investigation, control measures were already in force, showing that dust may be eliminated to a certain extent and oftentimes to a safe concentration. Table V shows the results of an engineering study of the control measures practised in some of the mines, and clearly depicts the effective reduction of dust in many of the occupations.

Another example is indicated in the results of a study now in progress in connection with mercurialism among workers in the hatters' fur cutting industry. Table VI shows the exposure to mercury dust and vapor of some of the workers in this industry under controlled and uncontrolled working con-

TABLE V

SUMMARY OF RESULTS CONTRASTING THE DUST EXPOSURE OF MINE WORKERS UNDER CONTROLLED AND UNCONTROLLED WORKING CONDITIONS

Operation	Dust Concentration in Millions of Particles per cu. ft. of Air		Remarks
	Controlled	Uncontrolled	
Firing charge	40	834	Unless at least 15 minutes elapsed after firing a charge, miners found to be exposed to high dust concentrations.
Loading coal or rock	32	636	By wetting the loaded material the dust count is reduced as shown.
Loading coal	4-26	291-1,138 *	Mechanical loading decreases the dust exposure as indicated.
Drilling	33	568	Wet drilling is effective in reducing the dust concentration. Further reduction would necessitate exhaust ventilation.
Hauling coal in mines	1.2	17	Wetting coal and empty cars reduces dust in haulageways.
Preparation of coal	24	380	Wet breakers reduce dust counts as shown.

* The lower result is associated with the hand loading of wet coal while the higher average is based on the hand loading of dry coal.

ditions, and that where some measure of control is practised (segregation or local exhaust ventilation), a material reduction in the exposure has been effected. It is our belief that in the case of blowers such reduction may be effected by mechanical enclosure and local exhaust ventilation, and, with shippers, by a general system of ventilation sufficient to change the air in the storeroom frequently enough to bring the mercury concentration to a lower level. Unfortunately, in the present investigation, it has been impossible to find a plant in which an attempt has been made to reduce the exposure for these two occupations.

TABLE VI

EXPOSURE OF HATTERS' FUR WORKERS TO MERCURY DUST AND VAPOR UNDER CONTROLLED AND UNCONTROLLED CONDITIONS

Occupation	Total Mercury Exposure in mg. per 10 cu. m.		Method of Control
	Uncontrolled	Controlled	
Blowers	4.6	...	None practised
Shippers	7.2	...	" "
Cutters	4.0	1.8	Local exhaust ventilation
Sorters	3.8	1.7	"
Brushers	3.1	1.2	"
Drummers	2.5	0.6	Segregation
Clippers	1.5	0.7	"

While the chromium plating study was being conducted, exhaust ventila-

tion methods for the removal of chromic acid mist were also investigated. Figure II shows the relation between the degree of air velocity at the exhaust ducts and the amount of chromic acid in the air.⁶ It is evident from this study that in order to keep the chromic acid content in the air to an amount less than 1 mg. in 10 cu. m. (the minimum amount found to cause no damage to the nasal septum), at least 1,500 feet per minute of air movement at the face of the duct is necessary, especially at the higher electric current densities commonly encountered in electroplating.

Perhaps one additional illustration of the rôle played by the engineer in the control of industrial hazards may

FIG. II—Relation between air velocity of local exhaust system and amount of chromic acid in air for different current densities

be mentioned at this time, to show the varied and important problems confronting him. In the study conducted with health hazards involved in cleaning castings by means of abrasive blasting,⁷ it was found that the only practical safeguard was to provide the worker with a mask or helmet of the positive pressure type. In studying the efficiency of such devices it was found that a relationship existed between the amount of air supplied to the helmet and the concentration of dust inside the helmet during blasting. In an attempt to determine the optimum air volume to be supplied to such protective devices, it was necessary to obtain dust samples from inside the helmet while varying the air volume, at the same time maintaining the dust concentration in the sandblast room (outside the helmet) constant. Figure III shows the results of such a study and clearly indicates that the positive supply of 6 cu. ft. of dust-free air per minute will protect a worker under the operating conditions now in practice in sandblast rooms. The ultimate criterion of protection, however, is the result of dust determinations of the air within the helmet, that

is, the air actually breathed by the worker and not the volume of air supplied.

From some of the examples cited in this paper it would seem logical to take appropriate measures for their control. That the problem of industrial hygiene is of considerable magnitude is evinced by the fact that we now know that the industrial population experiences high morbidity and mortality rates, partly as a direct result of the working environment, and in addition the number of persons involved is rather large. According to the U. S. Census figures for 1930,⁸ in the manufacturing, mechanical and mining industries alone there are some 15 million persons gainfully employed, so that industrial hygienists are at once faced with the task of providing adequate health services for a large number of workers engaged in occupations that are known to entail an exposure, in many instances, to deleterious materials and conditions.

One is also confronted with the fact that, in this country, the majority of establishments are very small, too small in fact to conduct individual programs of industrial hygiene. From a study recently made by the writer in a typical industrial area,⁹ and from the Census data of 1930, it is known that approximately 90 per cent of the industrial plants in this country employ less than 100 persons. The consensus of opinion among students of this subject is that the needs of industrial hygiene may best be cared for by local health departments. In fact, many of the state departments of health are now recognizing the necessity of a preventive program in industry and are considering ways and means for establishing such work as an integral part of their organizations.

It is not the purpose of the present paper to delve into the reasons for the necessity of industrial hygiene work in health departments, except to indicate

that once such a program is initiated, the engineer's rôle in it will be an important one, since the task of prevention will largely lie in his hands. It is probably apparent by now from the brief discussion given herein that in order for an engineer to carry on such work he will have to be thoroughly trained in industrial hygiene and be familiar with industrial processes. Such a person should be well grounded from both a theoretical and practical viewpoint in the fields of microscopy, gas chemistry, physiology and mechanics of ventilation, industrial sanitation, illumination, and, most important of all, he should have a broad public health viewpoint. It is apparent that neither a sanitary, mechanical, nor chemical engineer, *per se*, exactly fulfils these requirements. But, there is no reason why an individual with basic engineering training cannot in time be metamorphosed into an industrial hygiene engineer.

In closing, it is well to emphasize one

point; namely, that occupational diseases are in a large measure preventable and the degree of prevention exercised by a community will be reflected in the general health status of that community.

Scorpion Deadlier than Black Widow Spider

MORE lives have been lost in Arizona from the sting of scorpions than from the bite or sting of any other venomous insects or reptiles according to the records of the Arizona State Board of Health. The records disclose 35 deaths from poisonous insects and reptiles in the past 6½ years, of which 25 were caused by the sting of the scorpion.

This record has caused the State Board of Health to declare the scorpion as the greatest death menace

in the state among the insects and reptiles, and far more dangerous to human life than is the black widow spider about which so much has been written recently. . . .

Considering the high mortality associated with insect bites in Arizona, it is hoped by the Board that in the near future some biological house will establish research work to determine the feasibility of providing an antiserum for these serious accidents.—Arizona State Board of Health.

Montreal, Canada*

IT is obvious that in order to consider mental hygiene in its relationship to the public health organization of a province, it is necessary to set down, in a brief but comprehensive manner, what is meant by mental hygiene and also what is the provincial responsibility for public health services.

To begin with the latter, we may say that, despite a consistent and insistent demand from those interested in public health for greater interest in and participation by the federal government in the field of public health, there is no disposition to free the province of its primary responsibility for the care of the public health.

In times past, the province made the health laws and regulations, and then passed to the local administrative authorities the responsibility for their enforcement. This has, in general, resulted in the creation of reasonably adequate public health departments in the larger centers of population, the residents of which were willing and able to finance such departments. City health departments are, to a very large extent, autonomous units.

With the demand for public health service in the towns and rural areas

which had, in fact, little or no service, the provinces came to accept in varying degrees an increasing measure of responsibility for financial assistance, advisory services, and supervision. Today, most of our rural health units are, in practice, decentralized units of a provincial service, with the province supplying practically all the services in such fields as sanitary engineering and tuberculosis control. In other words, the provincial health department no longer confines itself to law enforcement, and supervisory and advisory service, but is actually an operating agency in those fields of public health which, for one reason or another, cannot be fitted to advantage into the local public health organization, except perhaps in the largest centers of population.

This point is elaborated because we are coming to accept mental hygiene as one of the services which should be organized on a provincial basis, along lines very similar to what has been found most effective in tuberculosis, cancer and venereal disease control by certain of the provinces. In no other way does it seem possible to bring to all the people of the province that part of the mental hygiene service which must be provided, or at least directed, by a specially qualified staff. Few local areas could finance the service,

* Read at a Special Session on Mental Hygiene of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

and even if they could, there is not enough staff available, nor is there the need for such staff, to work on a full-time basis, in local areas outside the cities.

Mental hygiene is an essential part of any health service for the reason that personal health depends upon a combination of both physical and mental fitness in the one individual. If we accept the main purpose of public health as that of increasing human happiness through the prevention of disease and the promotion of efficiency and effectiveness during a longer span of years, by developing to the full the potentialities of the individual, it follows that mental hygiene must be a part of public health.

Mental disease, mental disorders, and the host of great and small defects in personality constitute a greater deterrent to individual happiness and socially acceptable lives than do the corresponding abnormal physical states. True it is, as has been suggested, that the physical and mental are closely related, and that the cause of the symptoms of what may appear to be solely either a psychological or a physiological problem may lie in one or the other, or in a combination of physical and mental. Both physical and mental must be dealt with if either is to be treated adequately, for man is not merely a wonderfully complicated physical machine.

Every worker who comes in contact with human beings requires a knowledge of mental hygiene. To deal successfully with people, you must know people, which is another way of saying that you must understand human behavior. Not only is it necessary to have an understanding of the behavior of other people; it is infinitely more important to be able to recognize the basis for your own feelings and actions under various conditions.

Mental disease and mental disa-

bilities are so common that they cry out for preventive measures. Many of those who would do nothing justify their negative attitude by stating that not enough is known to permit of any worthwhile preventive effort. Surely this is not so, for can we not accept, at least, the importance of environment and the attitudes of parents or teachers with regard to the mental health of the child, and set in action some planned constructive work in the home and the schools? Surely we are satisfied that the treatment of the parent or the teacher is one very important part of the treatment of the problem child. Tuberculosis is being fought successfully despite the lack of specific means for the prevention and cure of the disease, largely through an attack on the physical environment.

It is desirable to consider some of the factors which are holding back the development of mental hygiene. The first that comes to mind is the public attitude toward mental disorders, an attitude indeed that is not limited to the public, for many physicians seem as reluctant as is the public to recognize or accept the reality of mental disease. A diagnosis that is qualified as "mental" is apt to be regarded by the patient's family as a social stigma.

A majority of children cannot achieve to the extent that their parents hope for and, unfortunately, in some cases demand. Parents who accept as a matter of course the differences which exist in the physical equipment of children may be and often are resentful of any suggestion that their child has been endowed with less intelligence than some other child. The result of this attitude on the part of the parents is that the child is frequently driven to tasks which are beyond his capacity. Every child should be assigned tasks which are sufficiently difficult to call upon his powers, but continued and repeated failures create in him a firm conviction

of his inferiority. Achievement and recognition, personal satisfaction and social approbation are necessary experiences for the child and the adult, to encourage each to persist in the learning process.

Prejudice and ignorance must be fought by enlightenment through education. Mental disease was not accepted as arising out of natural causes until a very long time after the supernatural was forgotten as a cause of physical disorders. The public and the professional attitude toward mental disease is travelling the same, road years later, that had been trod with regard to tuberculosis, venereal disease, and cancer.

There was a time, not so many years ago, when we spoke of a child welfare program, of a campaign against tuberculosis, or some other specific item of public health service, as if such movement were and could be separate and distinct. Later we learned that fundamentally all these supposedly different items were in reality much the same, with particular emphasis placed here and there. This must be true, because behind every health program, no matter what name is attached to it, there must be the same basic principles of general health.

There is no reason why this mistake should be duplicated as regards mental hygiene. Any suggestion that the solution of the mental health problem is to be found in the creation of a separate division or department, with the establishment of a new group of clinics, is doomed to failure. Mental hygiene will be effective in proportion to the extent to which it is integrated into all the public health services which touch the lives of the people.

Because of its relationship to other provincial departments, notably education, justice, and public welfare, the question arises as to whether mental hygiene should be organized as a part

of the public health department, or as a separate department of government, closely linked with others requiring mental hygiene in their services, notably departments of health and welfare. In any particular situation, we recognize that organization is based on the personnel available.

Mental ill health may bring the individual to a mental hospital as a patient, to the courts as a delinquent, or to a welfare agency as a social problem. This is because of a faulty system of diagnosis and our existing organization, for we know that such cases should be considered in terms of the personality problems presented and should receive the treatment indicated. Essentially, mental health and mental disorders constitute a medical problem and, therefore, mental hygiene should be organized as a part of the public health service. We believe this to be so in our teaching situation, and so we include mental hygiene instruction in the curriculum of our university department of public health and preventive medicine for the various professional schools. Personal experience dictates the desirability of such an arrangement for many reasons, not the least important of which is the effect of the arrangement upon the attitudes of the personnel of the department in all the teaching.

This should in no way minimize the effort to bring mental hygiene into the educational system, the courts, and the public welfare services. It may be said that one of the major responsibilities of the mental hygiene director in the public health service will be to extend his field in order that he may give direction and help to leaders in other departments and professional fields.

In stating the program for a mental hygiene division in the provincial health service, it is possible to enumerate a vast number of items and to present arguments which would justify their

inclusion. In the future, they will likely all be included, but at our present stage of development, it seems wise to adopt a more limited and circumscribed program, because it is better to be specific to begin with, to take one step at a time. Furthermore, as the amount of money will always be limited, it is important to expend what sum is available upon those activities which will give the greatest return through doing the greatest good for the greatest number.

The modern public health movement came into being during the latter part of the 18th century as an expression of humanitarianism. It was not long before the principle came to be accepted that care of the public health was not only Christian but was good business, and soon it was proclaimed that public health pays.

When we say that the first item on our mental hygiene program must be the provision of adequate care for those who, through no fault of their own, are in need of institutional treatment, we might be tempted to add, in a somewhat apologetic tone, that "humanity demands this," whereas the truth is that it is always "good business" for any community to take care of its sick, whether the disorder be physical or mental.

Mental hygiene has a further difficult task. There are individuals who are born with those varying degrees of low intelligence which demand special educational facilities if each individual is to be trained so as to be, within the limitations of each, a self-supporting, socially acceptable citizen.

The special institutions for treatment and training are a part of the mental hygiene service just as the sanatoria and other institutions are part and parcel of the tuberculosis control program. Institutions are mentioned first because the provinces had accepted responsibility for institutional care and

provided institutions long before mental hygiene was even thought of. Even though the institutions may not be adequate, it is around them that we may hope to develop the provincial mental hygiene program.

Next on the program comes public education. The reason for this is obvious. First of all, the public must be informed as to the gravity and extent of the problem. In other words, public interest must be aroused through an understanding of the situation as it exists and so be prepared to support, financially and otherwise, the mental hygiene program.

The real object of arousing interest is to seize the opportunity of presenting a plan for meeting the need. It is fair to say that mental hygiene has suffered seriously because certain irresponsible persons have led a section of the public to believe that mental hygiene is some sort of 'magic system' which can furnish a formula for solving all the personal and social problems of mankind.

It is essential that public instruction be fairly conservative, and that it express and interpret to the public the generally accepted opinion of those who are qualified to lead in this particular branch of science. At the same time, attention will be given to combating the old superstitions, which still prevail, regarding mental afflictions. This alone will require much time and effort because old ideas die hard.

Past experience would seem to justify a feeling that while there is a very definite place for health education directed toward one specific objective, a considerable part of the continuous instruction of the public in mental hygiene, by means of the printed word particularly, should be as a part of the whole health teaching. Unless it is so integrated, the mass of the public will fail to accept that mental hygiene instruction is part of the whole, and

so will be perpetuated the false idea that mind and body are separate and unrelated.

The instruction of the public in mental hygiene should come under the division of health education of the provincial department of public health. The machinery which already exists can thus be used. The provincial baby book can and should include consideration of the development of the whole child, mentally as well as physically. Health teaching which has to do with personal health as distinct from the control of the physical environment cannot deal adequately with the particular subject under consideration unless it include a study of the mental life of the individual.

Once public interest has been aroused, there will come a demand for information. As has been suggested, the division of health education in the health department can be used to meet much of this demand. In the health department is found also another medium for the education of the public. The public health nurse has proved to be the most powerful force in the continuous dissemination of health information to the public.

In speaking so highly of the public health nurse, it is not with the idea of disparaging the importance of other public health workers as health teachers. Because of the number of public health nurses, their close association with the families through home visiting, and their already established place in the field, they are, in effect, the health teachers of the community.

If the public health nurse, or anyone else, is to teach mental hygiene, she herself must have a fairly thorough knowledge of the subject. Staff education is one of the most important items in the provincial mental hygiene program. Staff education should begin with members of the provincial department itself, and extend gradually to

staffs of health, social, and educational agencies throughout the province. This is essential to bring existing staffs up to date in their equipment for teaching. Continuous staff instruction in all fields is recognized as necessary, but we cannot hope that new appointees will come prepared in mental hygiene until there is adequate instruction and experience during training in medical schools, schools of nursing, schools of public health and social work, and also in normal schools.

Just as intelligent students have made use of knowledge regarding personal hygiene for their own benefit as well as that of their clients, so the same intelligent students will find in mental hygiene a great personal asset to assist in solving the problems of life which all must face. It would be fair to say that all students should have mental hygiene training.

If we are to have sound instruction, then we must have competent teachers, and here is one of the most difficult needs to be met, because of the lack which exists and the time it takes to develop teachers.

In the provincial organization are found the staffs of the various provincial mental hospitals. It is no reflection upon the members of these staffs to say that, because of a tremendous pressure of work, they are apt to develop a somewhat narrow institutional point of view. It seems desirable, both for the staff and the public, that there be organized mobile mental hygiene clinics, staffed from the mental hospitals, to provide service. This would serve also to broaden the field of interest and experience of the institutional staffs by bringing them into contact with the non-institutional type of case; it would provide for them an opportunity to learn, through clinical experience, the significance of behavior symptoms in the child, and to come in intimate association with the workers

from community organizations, many of whose problems are essentially concerned with the mental health of their clients.

While recognizing the importance of the mental hygiene clinic, which should not be disguised under another name for fear of using the word "mental," and looking upon the clinic as an essential unit in the mental hygiene program, it is not to be understood that all those who require mental hygiene service are to pass through a special clinic. Indeed, the only hope of bringing mental hygiene to the masses is through the medium of the general practitioner of medicine, the pediatricist, the well baby clinic, and the public health and social worker. The mental hygiene clinic should serve as a center for the diagnosis of difficult cases, referred by physicians, health and welfare agencies, schools, and courts, after which treatment will be prescribed to be carried out, in most cases by the referring individual or agency. Cases presenting unusual problems may be carried by the clinic staff.

The clinics should be centers from which would radiate, not only community leadership in mental hygiene, but also sound teaching and guidance. The clinic may also be used as an outpatient department of the hospital to supervise discharged and boarded-out cases.

So far, it will be noted that the program suggested for the provincial health department is the acceptance and inclusion of well tried and proved pieces of work in the mental health field. It is very questionable if official agencies should go any farther. It would seem better to leave to the voluntary health agency the responsibility for pioneer work in mental hygiene, and for the official department to absorb new items just as soon as the soundness and practicability of these are established, but not before.

Those who believe that parent education as regards its content and technic is sufficiently established to warrant its acceptance as an integral part of mental hygiene service will expect to have it included. Those of us who would like to see more consideration given to the subject before expressing approval of content and technic would prefer to leave parent education to the voluntary agency for the time being.

It is difficult to visualize public health progress without the leadership, stimulation, and criticism of the voluntary agency. The nonofficial should be complementary to the official. This is particularly true in a comparatively new field which seems so vast in its potentialities that it creates a feeling of helplessness in the minds of some.

The size of the problem should not daunt us for, in proportion to the size, results will be attained. What is justified is a spirit of caution which brings us to pause and to endeavor to ascertain what is to be done first of all, and what are the second and third steps.

We cannot wait forever to make sure that there will not be mistakes, but we can allow the voluntary agency to conduct the studies and demonstrations from which the official department may hope to learn the most effective means to attain its objectives.

It is for this reason that the official authority should encourage and support the activities of the voluntary mental hygiene organization in carrying out those functions which can be better dealt with by the voluntary agency.

To sum up, what I have said is this—Because we deal with individuals, mental hygiene cannot be divorced from physical hygiene; mental hygiene appears to be one of the public health activities which, at least outside of the larger centers of population, will have to be conducted on a provincial basis; the logical location of mental

hygiene in university teaching or in public health service is as a part of public health, given a full appreciation of the necessity for intimate association with other professional services; the program for the present should be limited to those items which experience has shown to be of value and which are administratively possible, namely, institutions for the treatment of mental disorders and for the training of mental defectives; there must be a program of public education and a definite provision for staff education, with promo-

tion of adequate instruction in professional schools; there must be organized mental hygiene clinics, staffed from the mental hospitals, to provide service and also to offer facilities for the clinical experience required to prepare the teachers needed for carrying out the educational program; for the time being, the program may be limited, and the voluntary mental hygiene agency encouraged to pioneer in this field, with the official department gradually absorbing tried and proved pieces of work.

Armistice Day to Thanksgiving

Still the Greatest Mother

Physical Preparation for School Admission*

RICHARD A. BOLT, M.D., DR.P.H., F.A.P.H.A.
Director of Cleveland Child Health Association, Cleveland, Ohio

YEAR after year we continue routine physical examinations of children on school entrance. We find practically the same defects in about the same percentage of cases. We record the findings more or less accurately and completely. For various reasons we find it difficult to secure prompt and effective correction. Hampered by his defects it takes the child a year or two to adjust himself to the new order of things. This is decidedly harmful to the child as well as expensive to the school.

We know that children with depleted nutrition, with defects of sight and hearing, with dead or dying teeth, with enlarged and infected tonsils, cannot take full advantage of the educational procedures which are offered. School physicians and nurses are fully aware of this, and teachers soon recognize the relationship between poor physical condition and the ability of the child to measure up to standard in the daily program.

School medical inspection was among the first public health measures to be applied to children. As early as 1842 France issued a decree for school inspection by physicians. In the United States the first law relative to medical inspection was passed in Connecticut in 1899.

Since then we have accumulated a great deal of experience in developing routine medical inspection and in providing a follow-up by public health nurses; yet it must be confessed that in many places less real progress has been made in the early correction of defects and the inculcation of health habits than in any other phase of child health. Why should this continue?

The study of physical defects among school children in New York City, conducted by the Research Division of the American Child Health Association, showed clearly that a considerable proportion of the defects discovered during the course of routine medical examinations were not corrected. A number of pertinent questions were raised:

1. To what extent have school health staffs been remiss in following up the case and in impressing parents with its importance?
2. Is the lack of response on the part of parents due to apathy or neglect?
3. To what extent is lack of corrective facilities, within the financial means of parents, to blame?
4. Is it possible that the character of the examination in the first place has been responsible for unduly encumbering the records with matters which are not as serious as they appear? Is this one of the reasons why parents fail to respond? ¹

The failure to obtain results was due largely to the method of recording the defects, to a conflict of opinion which prevented continued follow-up, and to the fact that the parents did not coöperate with the school authorities in carrying out the recommendations.

* Read at a Joint Session of the American Association of School Physicians and the Child Hygiene Section of the American Public Health Association, at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

To this must be added the inability of many parents to pay full medical fees.

In a survey conducted by the National Organization for Public Health Nursing² an appraisal was made of the quality of work performed by public health nurses of 57 agencies in 28 communities throughout the United States. In order of quality this survey rated the nursing services as follows:

1. Prenatal care
2. Care of the sick
3. Postpartum and neonatal care
4. Health supervision of infants
5. Disease prevention including—
 - a. Tuberculosis control
 - b. Communicable disease control
 - c. Syphilis and gonorrhea control
6. Health supervision of preschool children
7. Health supervision of school children

It is significant that school health supervision should fall at the very bottom of the list. Nursing follow-up for school children undoubtedly has a good deal to do with the response of parents in having defects corrected.

Neither of these surveys, it seems to me, touches the mainspring of the difficulty. When the child enters school over 50 per cent of the opportunity to prevent certain communicable diseases is over. If suitable immunization measures were carried out in the preschool period there would be fewer cases of infectious disease arising in the schools. Many of the defects from which the child suffers in school have been acquired before school entrance and have remained unnoticed and uncorrected for such a long time that the parents have overlooked their importance. It is only in the school environment itself that the defects become noticeable. There they impede the progress of the child.

It is well known that the babies and infants up to 2 years of age, on the whole, have received exceptionally good care. This is the result of effective public health and preventive pediatric measures which have been continued

in spite of the depression. The great majority of children arriving at the age of 2 years have been under medical and nursing supervision and are in good condition. It is during the period from 2 to 6 that these children get out from under organized social control, and that the parents neglect to carry out measures necessary to prevent defects, or to have them corrected when they occur.

If preschool children were examined thoroughly by competent medical personnel and proper follow-up were instituted, there is no question that a great deal of the load of medical inspection during the first years of school life could be lifted. The children would gain immeasurably in having the defects corrected before school entrance; the school would be in a much better position to adjust the children earlier to its curriculum.

We have definite knowledge of the nature and extent of defects from which preschool children suffer. In many instances we are able to prevent or correct them. We have adequate professional skill to make the corrections. I am convinced the difficulty is not so much the lack of knowledge and proper technics to prevent many of the defects of childhood, or to correct them when they have occurred, as the lack of a properly coördinated system of child welfare to carry the excellent results which have been obtained in infancy over into the preschool and school years. If this could be accomplished we not only would help the children to better health and earlier school adjustment but an enormous amount of money would be saved which now is expended in attempts to get corrections carried out through the schools. The schools then would be in a position to devote themselves more to the health education aspects of health supervision.

The gap may be filled either by extending the work from the infant

welfare centers to cover the preschool child or by pushing back the school health work to join with the infant welfare. A continuous health record of the child from infancy through school life would be of great value.

The problem, therefore, resolves itself not into technical—medical, dental, and nursing—procedures; but into a program of community organization along socio-medical lines. Up to the present we have attempted to reach the preschool child through family physicians, general health work, specialized services in day nurseries and nursery schools, and sporadic efforts of preschool drives. Undoubtedly this has called to the attention of parents the condition of preschool children and has stimulated a certain number to have corrections carried out before school entrance; but it has been carried out in such a haphazard manner that it has reached only a small proportion of the preschool population. If we are to secure results for older children comparable to those in the infant welfare field, we must develop our program for the preschool group.

It is true theoretically that each family should have its own family physician and that the physician should follow the child right on through school. When it comes to a practical application of corrections, however, we find that not more than 10 or 15 per cent of the families can afford private physicians' services for preventive and corrective work.

Abundant experience has demonstrated that the most practical method of reaching large numbers of children at minimum cost is through well organized health centers. Another possibility, as has been suggested, is an extension downward of the school medical service. The kindergarten is still a feature of a number of the public school systems in America; but in many places it has remained bound to methods which have become antiquated. A number of kindergartens throughout the country, however, are transforming themselves gradually into what might well be called nursery schools.

England has found it possible through nursery schools to secure the correction of a great many of the defects of preschool children. If the kindergarten system of America extends its influence gradually downward, there is great opportunity for the medical service to concentrate on this period and thus secure the correction of defects at a much earlier time.

The excellent results secured by the health care of children in the best conditioned day nurseries and nursery schools give promise that a wider extension of preschool preparation for school will bring about desired results from the standpoint of parents, children, and schools.

Milk

YOU don't have to be a calf to enjoy milk, for there is no substitute for this indispensable food in the human diet. Use it, therefore, in liberal amounts in your daily diets, whether you want to slenderize or become more

ponderous, or merely want a protective food that will help to maintain the vigor and stamina of a comely and well-formed body.—James A. Tobey, Dr.P.H., Radio Talk, Milwaukee Annual Meeting.

Part the School Nurse Plays in the School Health Education Program*

ELMA ROOD, R.N.

*Associate in Charge of Health Education, Tennessee Valley Authority,
Knoxville, Tenn.*

A WELL KNOWN leader in public health work once gave this advice to his associates: "Whenever you are asked to outline a tentative program, set up your plan as ideally as possible, and then if you have to, cut it and modify it according to the conditions in which you must work," which is just another way of saying "Hitch your wagon to a star." If we put this advice into practice in outlining a program for the school nurse, we shall consider in this paper how the *best* school nurse in the most favorable school situation may be able to contribute most to the aims and purposes of general education and to the school health education program in particular.

Of course the term "best" is one which is subject to a great variety of interpretations depending largely upon the viewpoint of the person doing the judging. No two people in the world may agree on the requirements for "best." Perhaps no two people would agree on what is "best" as applied to a school nurse. Most people would be influenced indirectly in giving an opinion by the many and well known controversial questions bearing on this subject. This topic does not call for

a discussion of these unsettled problems; however, no opinion of the way in which the school nurse may do her best work can possibly be expressed without touching upon some important and controversial issues.

There are two major factors out of the many that condition the work of the school, which influence the contribution that the school nurse can make to the health education program. The first of these factors is the nurse herself, her personality, preparation, and experience. The second factor is the school, its leadership, philosophy, scope, and the vision of the teaching staff.

First let us consider the nurse and some personality traits that will be likely to contribute greatly to her services. Excellent health—physical, mental, and social—and an abundance of energy and good nature help her to be a constant teaching example. She likes people and is able to work harmoniously with them. She especially likes and enjoys children, and her attitude on this point is apt to influence the whole school health program. Mental alertness, initiative, courage, stick-to-it-iveness, and a moderate amount of aggressiveness are all qualities which help her to find and develop latent possibilities in the school field. Needless to say, enthusiasm for and belief in her work

* Read at a Joint Session of the American Association of School Physicians and the Public Health Education Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

color her personality and influence all of her contacts.

The preparation of this school nurse for her work is likewise of great importance. She has a good background in general education, especially in the biological sciences. She has had excellent basic health training in which she has gained an understanding of the growth and development of normal children and of methods of conserving and protecting this development. She has had a course in community health in which the major emphasis was placed upon the educational aspects of the public health field rather than upon the clinical. She has a thorough knowledge of and ability to apply principles that govern the teaching and learning processes, and these principles are in accord with the most enlightened ideas on education. She understands and appreciates the teacher's work and influence with children and with parents, and in addition she has ability to inform herself on the content of the curriculum, and the extra-curricular activities which are found generally now in the public schools. This gives her a valuable background for advising on ways to integrate health into the child's day. Contacts with normal children have been obtained in a nursery school, summer play school, or camp, or possibly in teaching experience, and this is an invaluable background for community work. These contacts have modified the approach and attitude so often developed through caring for sick children. She has also had experience in the generalized public health field and this has given her a very good idea of the whole community program of which school health is a special and important phase.

In addition to this preparation the nurse is constantly studying to keep abreast of a rapidly developing field. Whenever she has realized a weak spot in her preparation, she has reinforced

this point with a summer course or a special line of experience.

The preparation and background of this nurse is thus equal to or greater than that of the teachers with whom she works, so that she is fully acceptable to them in the capacity of consultant and adviser. This relationship is of tremendous importance and can hardly be overestimated for its effects upon the program.

Now let us see what factors there are within the school itself that favor the maximum contribution of the school nurse. We must recall again that "best" is an unknown quality when applied to the school also, but that research in education and its outcomes in terms of growth and development of children, seem to indicate certain trends in general education that are increasingly acceptable to experienced leaders in this field, and that should be applicable to health education since this represents a very closely interrelated phase of all education.

The first factor in the school that exerts an influence upon the work of the school nurse is found in the school administrator. As the educational leader he determines quite largely the philosophy that shall guide the learning process, and because he appreciates that his staff should have a clear-cut understanding of this educational philosophy, early in the school year some basic principles are evolved and interpreted such as, for instance:

Each child to be encouraged to do his best and to have such experiences as will help him to do this; each child to have opportunities to exercise originality, initiative, and responsibility in deciding questions or problems that arise in his own life; each child as a member of a social group to have a part in initiating, planning, executing, and judging in coöperation with others; each child to meet the problems of life daily in the classroom,

and so to be ready for the broader and more responsible life of the community in which he must take an increasingly active part.

Such a philosophy welcomes health as a quality which is associated with many experiences of living. It becomes a part of this philosophy that each child shall be intelligent, voluntarily coöperative and, as far as possible, self-directing on every health procedure. To accomplish these aims requires the highest type of education.

The scope of the school program influences directly the breadth of the work of the school nurse. This school is extending its influence in two directions, downward in the interest of the young children who represent the future school population, and upward and outward to the adult members of the community. Therefore it no longer represents an institution only for children, but leads out into the growth and development of the whole community. This type of community program is an open door to the kind of health education that will be a challenge to the school nurse.

We have named last among the factors that influence the work of the nurse, the vision of the teaching staff. It is a question whether this factor does not deserve the leading place from the standpoint of its potentialities. The teacher with vision sees each child as a person—whom she must know very well if she is to contribute her maximum to his development. She constantly tries to broaden the child's experiences and so pulls in those activities that will help him most to grow. She finds and welcomes situations that require personal and group decisions since these give the child practice in intelligent thinking and judging. She knows that environments sometimes change completely under a child's fingers, and that the attitudes of a whole community may be touched by a child's interests and

feelings. She recognizes that health is something that functions in the classroom every hour of the day, that it follows a child into his home and out into the community, and that she must be alert to find the learning opportunities in this broad experience and to make them alive and meaningful.

With such vision what better ally can the school nurse have than the classroom teacher!

Now that we have our setting for this school nurse let us see how she plays her part in a community health education program, in which the common barriers of age and subject are removed so that health can effectually penetrate into public consciousness as one determiner of effective citizenship.

Recognizing that she is engaged in the most potentially far-reaching and constructive phase of the public health program of the community, she has established early and close contacts with the organized health department, not only as a means of instituting measures for the protection of the school, but to gather suggestions on basic problems which may be incorporated into the learning of children.

In her official reports to the health department she is constantly interpreting health as an aspect or modifier of social and economic problems, rather than as a subject, and as a quality so tied to many interests in the community that she does not expect nor desire that every educational effort bearing on health should be so labeled. In discussing results to be sought, she illustrates concretely that by far the most valuable outcomes in the form of feelings, desires, and attitudes, are often of an intangible nature, not subject to rating by the ordinary type of appraisal form, or capable of being totalled on an adding machine.

She keeps the health department informed regularly on health conditions and progress, and obtains advice on

necessary technical steps to be taken. She counsels on ways in which services to be rendered by doctors and nurses may be of the maximum educational value. She serves as the go-between for the school and the health department in making use of community resources in the interest of children, and in carrying out special directions in times of emergency. She works closely with the official health department on plans for reaching the preschool group, taking an active part in such adult courses as are built around the problems of the young child. She also plans with the teachers to make the preschool work as far as possible a part of the social training of school children.

She assists in the preparation of educational material for use in the Parent-Teacher or other organizations on such subjects as bear on child health and protection, and takes part in incorporating this knowledge into the understanding of the community.

She is constantly interpreting to adult groups the needs of children and what the school is doing throughout the entire day to meet these needs, and through these contacts she finds and develops lay participation in all health services rendered to the school.

Her contact with the teachers is close, friendly, and cordial, and a spirit of helpfulness pervades all services rendered. She is personally interested in the health of each member of the teaching staff and sometimes talks over with them their everyday health problems. She is constantly alert to see dangers or hazards, whether physical, mental, or social, as these may affect any one in the school, and quick to bring these to the understanding attention of the school administrator or teacher. She works closely with all departments of the school in bringing about the most wholesome environment, emphasizing the possible educational value of all problems to the pupils.

In all contacts with children she aims to be an example of health, and she plans ahead to make all these contacts as meaningful as possible.

In her relationship with parents she serves as an adviser, and constantly interprets the needs of and services rendered to children at different stages and phases of development. Believing that parents usually receive and act more readily upon advice which they seek, she fosters and develops a parents' consultation service at the school where constructive advice on child problems may readily be obtained.

At the beginning of each year the attention of the school is called to the value of an early inventory of health needs as a basis for a constructive program for the year. The nurse assists the school in arranging for health examinations of children, and plans definitely to have this procedure understood by teachers, pupils, and parents.

On the basis of the health inventory the nurse interprets the constructive work that needs to be done, especially calling attention to the importance of having the understanding and coöperation of the child whenever possible and advisable.

When follow-up work is begun the nurse supplements and reinforces the teacher's knowledge of the problem, by giving her pertinent information on home and community conditions affecting that specific problem. She also keeps the school informed on current scientific discoveries significant to an understanding of child problems, and on source materials of value to the teachers or for use by the pupils in special studies. She frequently passes over to the teacher the knowledge she has gained from her first-hand field experience with local conditions.

The school nurse is interested in every phase of community work, and is alert to discover and commend associations which are built with any phase of

health. On such subjects as require some technical training such as home care of the sick, or first aid, she takes an active part in instruction, in the school to assist the regular teacher to carry it on more effectually after the demonstration is over, and in the community, to develop ability to conserve and build health in the home.

Activities mentioned thus far are concerned primarily with well children. In every school there are those who need special provisions either for physical reasons or because of some mental or social difficulty. To solve the problems of such children often requires the coöperation of many agencies and the nurse is ready to make her contribution to any constructive program outlined for an exceptional child. She follows up such recommendations as come within her field, and helps to secure understanding coöperation in the interest of the child's welfare.

The nurse contributes all data possible on the health history and status of each pupil, as a part of the cumulative record which shows all phases of his growth and development and which accompanies the child throughout his school life. As these histories grow, she prepares material in the form of graphs or charts to help the school better to see its health needs, its progress, and the problems on which special emphasis may be indicated.

As the school grows in its awareness that health is associated with all phases of its program, the nurse becomes increasingly an adviser on the health aspects of such activities as the school lunch, swimming pool, picnics, field trips, excursions, hikes, and contributes to the educational phases of these whenever possible.

From the illustrations which have been given it is seen that this school nurse is primarily an educator with a special background in the field of health, one who serves not only as a

guide to teachers, but as a teacher of parents; one who successfully coördinates school health with the public health work of the community, and merges her contribution into the coöperative program aiming to raise the level of child health and intelligence; one who does her part in making the school become the focus for the health educational work of the entire community.

The outlining of this program may stimulate questions as to its practicability, soundness, and economy—such questions, as, "Where could a school nurse be obtained to carry on such a program?" "Will school boards afford to employ such a person?" "Is it possible to carry such a program in a generalized service?" "Is it as worth while to provide a special health service for children as it is to provide a special service for workers in industry?" "Would the school physician, if there is one, welcome such a person in the school?" "Would it pay the community in hard dollars and cents to have this service as a part of the educational system?"

Some nurses may feel that this program is entirely too far away from present practices and standards in school nursing. Others may wish to start at once to prepare for just such a service, confident that opportunities open to the person who is well prepared. It is likely that this ideal is within reach of many nurses at present in the field who have a clear vision of its possibilities and determination to secure the necessary preparation, and experience.

Judging by the way in which other civic enterprises have grown because a vision has been translated into action, it would be reasonable to predict that such school nurses will be developed, as individuals catch the vision of the potentialities in this field, and realize the truth and tremendous significance

of the statement made at the White House Conference to the effect that "civilization moves forward on the feet of little children." Training facilities always materialize in proportion to the demands of the field. So far the demands for this type of service have come mainly from school administrators, many of whom realize the needs but have not succeeded in establishing such a program for lack of adequately trained personnel. There needs to be built a greater appreciation on the part of public health nurses that the education of the school child as a citizen

in the making, is building not only for present, but for future generations, and that by this means only 'will we solve many of the public health problems which now absorb so much of the time and energy of health workers with so little in permanent returns, that we must change our program from one which is largely corrective and palliative to one which is positive and constructive.

The school nurse who prepares herself to take part in such a program will be a contributor to the most advanced steps being taken in the public health field.

Swope Appeals for Health Fund

WITH more than one-third of the public health work in the United States supported by contributions to community chests and other private services, only \$1 per capita from both public and private funds is being spent for public health work in the nation, it was pointed out by Gerard Swope, chairman of the 1935 Mobilization for Human Needs.

Mr. Swope based his figures on a report submitted by the National Health Council, whose agencies are coöperating with the Mobilization. He pointed out that sound public health work required an expenditure of from \$2.50 to \$3 per capita annually.

Mr. Swope, who is president of the General Electric Company, made it clear that about one-third to one-half of the budget appropriated from tax money for public health went to support nursing services and that this was greatly increased by money provided by private health agencies for nursing service.

Exclusive of private-duty nurses,

there are in the United States about 20,000 public health and bedside nurses, of whom 40 per cent are paid for by private agencies, Mr. Swope declared, asserting that there were only one-sixth as many public health nurses in the United States as there should be. . . .

Much has already been done to reduce preventable diseases and epidemics and to prolong life, but much remains to be done in the fight to banish disease. Money can do it; money pays for nursing service, hospital and clinic treatment, public sanitation and food protection, and other measures for making better community health.

In the realm of public health there is, this year, great need for the private health agencies supported by money from community chests and other private sources.

To acquaint the public with the true health situation in this country, a campaign has been launched this fall under the sponsorship of the National Health Council, to hold in more than 400 cities of the United States town meetings to discuss matters of community health. In each city the meeting will be preceded by a community-wide inquiry into community health conditions.

Frequency of Immunizing Procedures of Various Kinds in 9,000 Families Observed for 12 Months, 1928-1931

SELWYN D. COLLINS, PH.D., F.A.P.H.A.

Office of Statistical Investigations, U. S. Public Health Service, Washington, D.C.

IN connection with a study of illness and medical care in a group of nearly 40,000 persons, made by the U. S. Public Health Service in coöperation with the Committee on the Costs of Medical Care, information about the various immunizing procedures was recorded. The data were collected through periodic calls to the homes by visiting nurses for a sufficient time to obtain a 12 month record of illness and medical care. All immunizing procedures reported as occurring during the year were recorded and for four diseases information was obtained about the history of artificial immunization prior to the study.

The 8,758 white families surveyed lived in 130 localities in 18 states and represented all geographic sections of the United States. Every size of community was included, from metropolitan districts to small industrial and agricultural towns and rural unincorporated areas. The observed group was fairly similar to the general population with respect to age and sex composition, percentage native born, and percentage married. With respect to income, the distribution was reasonably similar to the estimated distribution of the general population of the United States at the time of the survey. More details about the canvassed families are given in preceding reports.¹⁻⁷

Figure I shows the proportion of persons of specific ages who had been artificially immunized against smallpox, diphtheria, scarlet fever, and typhoid. These curves are cumulative in nature because they consider immunization* at any time in the individual's life. If the frequency of immunizations has

FIGURE I—Proportions of persons of specific ages who have ever been artificially immunized against certain diseases—8,758 white families, including 39,185 individuals in 130 localities in 18 states canvassed between 1928 and 1931.

In the absence of changes in past years in the frequency of the immunizing procedures, the curves would rise continuously; the use of diphtheria and scarlet fever immunization among children has increased in recent years and more children than adults give histories of such procedures.

* "Immunization" is used in this paper to mean the usual procedure for producing artificial immunity to a particular disease, such as toxin-antitoxin for diphtheria. All cases receiving such service are designated as "immunizations" whether or not the process actually produced immunity in the individual, except that histories of smallpox vaccinations are exclusive of unsuccessful vaccinations.

not changed in past years, the curves may be thought of as roughly corresponding to an accumulation of persons who have received artificial immunizations in a population kept under observation from birth to middle life. However, in the case of diphtheria, at least, the frequency of immunizations has changed; persons above 25 years at the time of the survey had passed the age of greatest susceptibility to the disease before the use of diphtheria toxin-antitoxin became widespread, and few persons of these ages have ever been artificially immunized. The same is true of scarlet fever, but there are so few immunizations at any age that the curve does not show the change so well.

In infancy and the preschool ages a higher percentage of the children had been artificially immunized against diphtheria than against smallpox. This finding is in agreement with that of the White House Conference report on preventive procedures in preschool children.⁸ In this country, however, a great many children are vaccinated for the first time when they enter school, and above 6 years the proportions vaccinated against smallpox greatly exceed those artificially immunized against diphtheria.

Smallpox vaccinations reach a maximum level of about 66 per cent by 16 years of age, after which there are relatively few primary vaccinations. Diphtheria immunizations reach a maximum of 43 per cent at 9 years; the reasons for the decline thereafter have already been discussed. Typhoid immunizations reach 10 per cent by about 17 years of age, with a second maximum of 12 per cent at 30 to 45 years which probably reflects the compulsory immunization of males in the military services during the World War. Scarlet fever immunizations reach a maximum of 4 per cent at about 13 years of age.

The curves in Figure I cannot be taken as representing active immunity at the time of the survey, particularly in the adult ages, because: (1) Many of the immunizations were done in childhood and never repeated; of the persons 20–24 years of age, only 19 per cent had been vaccinated against smallpox within 7 years, and at 35–44 years only 11 per cent had been vaccinated within that time. (2) Schick and Dick tests indicate that a large percentage of adults have developed immunity to diphtheria and scarlet fever without any artificial procedure or recognized attack of the disease. (3) The curves represent histories of artificial immunizing procedures and do not include histories of cases of the disease. In the older ages, histories of typhoid fever cases are about as frequent as histories of artificial immunization; among persons 35–44 years, 8 per cent gave a history of a case, and 12 per cent gave a history of an artificial immunizing procedure without a case; above 45 years, about 10 per cent gave a history of a case. In smallpox, only about 5 per cent of adults gave a history of the disease as compared with 66 per cent who had been vaccinated but had not had the disease. In diphtheria and scarlet fever the histories of recognized attacks are small as compared with the number who show im-

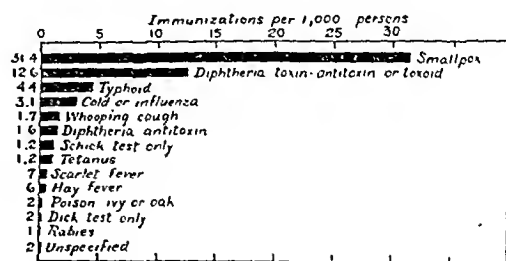

FIGURE II—Annual artificial immunizations against various diseases per 1,000 population under observation—8,758 white families canvassed periodically for 12 consecutive months, 1928–1931. (Rates based on 38,544 full-time person-years of life.)

munity by the Schick and Dick tests, but are not small as compared with artificial immunizations. At 13 to 15 years of age 13 per cent of the children gave a history of scarlet fever attacks as compared with 4 per cent with a history of an artificial immunizing procedure. At 9 years when the history of diphtheria toxin-antitoxin or toxoid was at the maximum of 43 per cent, 4 per cent of the children gave a history of recognized attacks of diphtheria. Among adults, about 7 per cent gave a history of diphtheria.

Figure I represents average percentages for the whole group of surveyed persons. In smallpox there are large differences in vaccinal status between the cities and rural areas. In cities of over 100,000 population, about 86 per cent of adults have been vaccinated as compared with 44 per cent of adults living in the open country. The proportions for towns under 5,000 and for cities of 5,000 to 100,000 population fall logically between these limits. Variations in different geographic sections were not so large.

Typhoid immunizations are more common in the rural open country and are least frequent in cities of over 100,000. The greatest variation, however, is geographic; among persons 15-19 years of age living in the surveyed southern states, 31 per cent had been inoculated against typhoid fever, as against 3 to 5 per cent in the other three sections into which the surveyed states were classified.

Urban-rural and geographic differences were not so striking in the case of immunizations against diphtheria and scarlet fever.

The only significant variations as between the sexes occur in typhoid inoculations among adults; the considerably higher frequency among males is presumably the result of compulsory immunization of men in the military services during the World War and since

that time in training camps and the like.*

Data for the 12 month period during which periodic visits were being made are presumably more accurate than the histories covering the whole past life. Figure II shows for this period the frequency of artificial immunizations of various kinds per 1,000 persons under observation. Schick and Dick tests made without prior or succeeding immunization during the year and diphtheria antitoxin administered to contacts are also included. Of the total of 2,279 immunizing procedures, 1,209, or 53 per cent (31 per 1,000 persons under observation), were smallpox vaccinations and another 487, or 21 per cent, were diphtheria immunizations. Typhoid immunizations are third in frequency with inoculations of cold vaccine not far behind. All procedures purporting to immunize against any disease are included; this study deals with the frequency of their use and not with their efficacy.

The cases of antitetanic immunization amounted to only 1.2 per 1,000 persons under observation, or 1.7 per cent of all accidents that were reported. The use of antitetanic immunization was largely confined to injuries by cutting and piercing instruments, 6.8 per cent of such injuries being followed by antitetanic vaccination.

Hay fever immunizations amounted to 0.6 per 1,000 persons under observation, or 11 per cent of the 226 cases of hay fever or asthma that were reported. Of the 76 cases reported as hay fever, 25 per cent had some immunizing inoculations during the year, but only 4 per cent of the cases reported as asthma had such inoculations. The percentage of hay fever cases receiving immunizing extracts seems large; it is probable

* More data on the variation of vaccinations and immunizations in cities of different sizes and in geographic areas will be included in forthcoming articles in the *Public Health Reports*.

FIGURE III—Annual artificial immunizations against certain diseases per 1,000 persons of specific ages—8,758 white families canvassed periodically for 12 consecutive months, 1928-1931.

that many mild cases of the disease that received no medical care of any kind were not reported.

Figure III shows, for the immunizations that occur more frequently, the rates for persons of specific ages. The data are plotted in 5 year classes to 25 years—an age grouping which shows essentially the same curves as would narrower age classes. Diphtheria immunizations during the study year were more frequent under 5 years than at any other age. Smallpox vaccinations, however, reach a peak at 5-9 years, the frequency being about the same under 5 as at 10-14 years. Typhoid immunizations are much more frequent from 10 to 20 years than at any other age. Scarlet fever, whooping cough, and tetanus immunizations are also confined largely to children. Cold vaccine has a small peak in childhood but the rates are higher in the older

ages. Hay fever immunizations show peaks of approximately equal size in childhood and about 40 years of age; although the numbers are small, the curve is probably fairly correct since these two peaks correspond roughly in age to peaks in the incidence of hay fever as reported in these families.⁶ The percentage of hay fever cases reported as taking immunizing treatments is twice as high for persons under 20 years as for adults over 20 years of age. In the case of tetanus also, the per cent of cutting or piercing accidents that were followed by antitetanic immunization was much higher for children than for adults.

SUMMARY

1. Between 60 and 70 per cent of adults have been vaccinated against smallpox at some time in their lives.
2. The present rate of artificial

diphtheria immunizations will eventually result in about half of the adult population with a history of such a procedure.

3. In the preschool ages a smaller percentage of children are vaccinated against smallpox than are immunized against diphtheria.

4. Immunizations against typhoid are more frequent in the South than in other sections of the country.

The General Reader

SCIENTIFICALLY and philosophically trained writers apparently have no idea how hard their books and articles are for the general reader; how much is included that few can appreciate; how many statements are dark and unintelligible to those for whom the book is ostensibly designed. An encyclopaedia or dictionary would seem to be compiled especially for the benefit of the public who are urged to buy it. But the seeker for knowledge who happens to have his curiosity aroused

in regard to the polarization of light will find the article in the *Encyclopaedia Britannica* beginning: "A stream of light coming directly from a natural source has no relation to space except that concerned in its direction of propagation, round which its properties are alike on all sides." Like the lovers in Dante's *Commedia*, the simple inquirer is likely to read no farther that day.—James Harvey Robinson, *The Humanizing of Knowledge*, 1924.

The Known and Unknown of *Bacillus Pertussis* Vaccine*

LOUIS SAUER, M.D., PH.D.

Northwestern University Medical School and the Evanston Hospital, Evanston, Ill.

DANISH State Serum Institute investigators and clinicians have made valuable contributions on *B. pertussis* vaccine since 1916. Miller¹ says:

The strains are kept on Bordet-Gengou medium until inoculated on the "vaccine medium" (3 parts nutrient agar (calf), 2 parts potato-glycerin agar, and 2 parts defibrinated horse blood). The 3 day growth is washed into 1 per cent formalin in physiological sodium chloride. After formalization for 1 week the suspension is centrifuged, resuspended in 0.5 per cent phenol in physiological sodium chloride and standardized to 10,000 million bacteria per c.c.

For nearly 20 years a standard technic has been in use—the total dosage of 2.2 c.c. is divided into 3 injections (0.5, 0.7 and 1.0 c.c.), given at intervals of 3 or 4 days. Madsen,^{2,3} found this ineffective as a curative agent; given as a prophylactic, 1 to 3 months before exposure, it failed to prevent the disease in 364 nonimmunes. The course was more frequently mild, however, and the percentage of deaths was lower when injections were completed a few weeks before symptoms appeared. Discussing F. McDonald's⁴ summary on *B. pertussis* vaccine, R. Smith⁵ cautions against hasty con-

clusions on pertussis immunization. He says:

Pertussis is such a dread disease that physicians and parents easily take "the will for the deed" so far as proof in relation to prevention is concerned. Enthusiasm has waxed and waned many times. . . . One is certainly justified in using vaccine in an attempt to produce immunity against whooping cough, but one must be honest with himself and with his patients in acknowledging that proof of its protective efficacy is lacking. One must guard against drawing conclusions from a few cases, from clinical impressions, or from uncontrolled statistical reports.

When whooping cough occurs during the first few years of life, its course is often influenced by age, previous health, nutritional state, stability of the nervous system, hygienic care (aseptic nursing), climate and season. In the vaccinated and nonvaccinated the duration and severity often vary greatly. In a crucial study of immunization only nonimmunes between 8 months and 3 years of age should be used. Children should be excluded if they ever had any persistent cough. The very young may not yet possess the power to elaborate immunity from injected antigen, regardless of its potency and dosage; children over 3 may require a larger dosage of antigen, or may already be immune. Because the communicability index for pertussis is about 75 per cent, appreciably more than 25 per cent of the vaccinated should escape the disease

* Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

when they are definitely exposed to infection. Exposure to infection is more likely to be early, intimate, repeated and prolonged when it occurs within the family. The best controls are, therefore, the nonimmune (nonvaccinated) siblings. Exposure occurs more frequently outside, but doubt may exist when vaccinated nonimmunes escape such transient exposures. Did the patient disseminate bacilli at the time of contact? did the vaccinated child aspirate bacilli? or, was the child immune before vaccination? Diagnosis should be verified by cough plates, repeated white cell and differential white cell blood counts. Of importance is the duration of the cough before exposure of the injected child occurs—also the time interval between vaccination and exposure. Because specific serologic tests are not an index of immunity, and without a reliable skin test,⁶ the ultimate test of immunity is exposure to infection.

Between 1928 and 1932, 394 selected young nonimmunes, average age about 14 months, were injected with an especially prepared *B. pertussis* vaccine.^{7, 8} Each child was injected with a total of 7 to 8 c.c. (approximately 70 to 80,000 million bacteria). Thirty intimate (familial) exposures to the disease in siblings have occurred; and 169 of the vaccinated children have been exposed (?) a total of 360 times in 7 years. No child injected with this Evanston vaccine has contracted typical whooping cough. A frail girl of 2 years, injected soon after recovery from measles, developed a very mild cough (1 cough plate positive, blood findings repeatedly normal) within 3 months after she had been injected with a total of 7 c.c.; her brother (control) was convalescing from typical pertussis at the time. In 1933, Macdonald and Macdonald⁹ reported important inoculation and exposure experiments on humans.

Two commercial laboratories were authorized by Northwestern University Medical School to make this vaccine according to detailed specifications. Freshly isolated, hemolytic strains are sent to them monthly; fresh, defibrinated human blood is used in the Bordet medium; the 3 day growth is scraped off; it is not washed; 0.5 per cent phenol in physiologic sodium chloride is used as preservative and diluent; the sterile product is standardized to contain approximately 10,000 million bacteria per c.c.; it is refrigerated until transported. Jobber, druggist, and physician are cautioned to keep it cold. Table I is a summary of vaccinations with approved commercial vaccines since 1932.

Thirty-three physicians in 19 states have reported a total of 2,945 vaccinations with approved commercial vaccines. The average age of their patients was well over 3 years. Seven children of 3 physicians, and a nurse, were willfully, intimately, and repeatedly exposed to the disease without contracting it. Only a few of the physicians ascertained the instances of exposure, but all reported their failures. A total of 130 known exposures and 21 failures were reported. Most failures occurred in children well over 3 years of age.

The prompt decrease in the incidence of typhoid fever in the Army and Navy, coincident with compulsory antityphoid vaccination in 1912, is accepted as evidence of effective specific immunization. Although typhoid vaccine has been perfected since then, the dosage augmented, and general hygienic measures have improved, typhoid fever still occurs in some of those exposed after vaccination. An authority recently estimated such failures at about 10 per cent. At first, toxin-antitoxin immunization against diphtheria failed to protect about 30 per cent of the injected children. Soon after scarlet

fever immunization was introduced, the number of injections was increased to 5, and the strength of the toxin appreciably increased. With the hope of decreasing the percentage of failures in pertussis immunization, children over 3 years will probably require a total of 10 c.c. or more of the approved commercial vaccine. One, 2, 2 c.c. would then be given in each arm, in 3 consecutive weeks.

Little is known about the factors which may cause failure—the antigen may be impotent when injected, or the individual may not possess the power to develop immunity. Little is known about the stability of the fraction which confers immunity. Endotoxin, prepared according to Besredka's method as described by Bordet¹⁰ was found to contain living *B. pertussis*. Mishulow, Mowry, and Scott¹¹ obtained a toxic filtrate from bacilli grown on horse-blood chocolate-agar with 1 per cent horse-serum beef-heart broth added. They produced the Schwartzman phenomenon with it. Gundel, Keller, and Schlüter⁶ prepared an endotoxin which was very toxic for rabbits and mice; skin tests with dilutions of it showed no specificity; nor was its necrotic action neutralized by the addition of convalescent pertussis serum. Regarding Krueger's¹² endo-antigen, McDonald says: "If the filtrate is water-clear, is one certain that 'cell metabolites' are the only masses filtered out?" Miller's recent complement fixation tests on rabbits, within a few weeks after undenatured endo-antigen was injected, seem to compare favorably with parallel tests on rabbits injected with the Danish vaccine. The relative impotency of the vaccine might be attributed, at least in part, to denaturation effected by the 1 per cent formalin. Truschina, Pechletzka and Murawjewa¹³ maintain that their bouillon culture filtrate purified by Huntoon's method, contains

soluble toxin which possesses specific antigenic properties. Dilutions of it produced positive skin tests more frequently in the nonimmune than in the immune.

No one has shown that immunization is possible with vaccine made from old stock strains, grown without blood. Leslie and Gardner¹⁴ maintain that "Phase I" strains yield the best antigen. Until it is known with certainty whether some strains yield more potent antigen than others, it is advisable to use recently isolated, hemolytic strains. They may probably be used as long as they fulfil the requirements of Leslie and Gardner's Phase I strains. It is of economic importance to learn whether other bloods, e.g. sheep, in the culture medium for general use by health departments, orphanages and foundling homes, will yield a safe and potent vaccine. The Michigan State Health Department vaccine, made with sheep's blood, is washed, that of the New York City Health Department is not washed. The work of Kendrick and Eldering¹⁵ and that of Park and Mishulow should determine, within a few years, whether safe and potent vaccine can be prepared without human blood.

The Helber counting chamber, with the vaccine diluted with Callison's fluid, probably yields more constant checks than the Wright or Harrison methods. Uniformity of the vaccine is important, but methods applicable for washed vaccines (Hopkins's tube) yield different counts when compared with unwashed vaccines of identical opacity. The Nephelometer has advantages after an accurate standard has been established, but the latter should not change color in the course of time. The Danish method of carefully matching the density of each new lot of vaccine with a well guarded standard tube of vaccine is simple, quick, and relatively accurate. It is our method of choice.

TABLE I
SUMMARY OF VACCINATIONS WITH 8 C.C. OF APPROVED COMMERCIAL VACCINE

	Number of Injections	Known Exposures	Failures	Age	Interval Between Injection and Exposure	Per Cent Protection
Private Patients (1932 to Sept. 1, 1935)	458	Familial 13 Casual 27	Gilroy Gilroy Kelly Mathews Pick	4 yrs. 7 yrs. 3 yrs. 4 yrs. 6 yrs.	6 mos. 6 mos. 2 yrs. 1 yr. 20 mos.	87.5
Evanston Health Department (1934 to Sept. 1, 1935)	604	Familial 14 Casual 50	Johnson Keefer Spencer Spencer	9 mos. 3 yrs. 2½ yrs. 4 yrs.	8 mos. 8 mos. 5 mos. 5 mos.	93.4
2 Orphanages	242	23	Trush	9 mos.	8 mos.	95.0
Total	1,304	127	10	Av. 3½ yrs.	Av. 8 mos.	Av. 92.0

Although some children may develop immunity within a shorter period of time, our records show that most children require somewhat more than 3 months for complete immunization. Lymphocytosis, quite like that of pertussis, often occurs within a month after vaccine injection. To give the 3 bilateral injections at shorter intervals (e.g., the 8 c.c. completed within a week) might hasten the immunity response. Work along this line is in progress.

Because whooping cough is a disease of early life, and as most of the deaths occur during the first 2 years, it is desirable to immunize as early as possible. Four hundred ("Cradle") infants, less than 6 weeks of age, have been injected with a total of 6 c.c. of the approved commercial vaccines. Since December, 1934, 168 have been given a total of 8 c.c. They withstand the injections remarkably well. There have been 9 subsequent exposures. Four of the children escaped, the other 5 contracted mild pertussis. It therefore seems that the best age is between the 6th and 8th month of life.

Warmth accelerates chemical change. Interrupted refrigeration, as during transit, a month on the druggist's shelf, or a few weeks in the physician's bag, acts deleteriously. Mishulow, Oldenbusch, and Scholl¹⁶ elicited comple-

ment-fixation reactions with the serum of rabbits, injected with *B. pertussis* vaccine that had been stored for several years at 8 to 10° C. Uninterrupted refrigeration of biological products is a desideratum.

Physicians inquire about the best sequence for immunization procedures and the importance of spacing. Fishbein¹⁷ says:

Perhaps the best plan would be to allow 4 months to intervene between successive immunization procedures. Because whooping cough causes more deaths in children under 2 years of age than diphtheria, measles, and scarlet fever combined, it is prudent to immunize first against whooping cough—preferably during the second half year of life. Four months later a single alum toxoid injection against diphtheria may be given. Four or more months after, when the Schick test is done, preferably in the spring or autumn, the smallpox vaccination may be done.

Very little is known about the effect of other diseases on the immunity response from injected pertussis vaccine. Two failures occurred in children who were injected with the approved vaccine soon after recovery from measles; another occurred in a girl of 6 who was injected soon after recovery from mumps; 20 months later she contracted typical pertussis. Her injected brother, who did not have mumps, escaped pertussis, although intimately exposed to her for weeks.

SUMMARY

Bacillus pertussis vaccine; like typhoid vaccine, is an immunizing, not a curative, agent. A time interval of several months is required for immunization to be complete. About 10 per cent of the children injected with a total of 8 c.c. of the approved commercial vaccine contracted pertussis when subsequently exposed to infection. Some of the factors which might interfere with the immunity response are controllable.

Observations Upon the Methods of Transmission of Amebiasis*

CHARLES F. CRAIG, M.D., F.A.P.H.A., COLONEL
U. S. ARMY, RETIRED. D. S. M.

*Director, Department of Tropical Medicine and Professor of Tropical Medicine,
Medical School, Tulane University, New Orleans, La.*

SINCE the widespread outbreak of amebic dysentery, originating in certain hotels of Chicago in 1934, the subject of amebiasis has attracted much attention in the United States and, because of the particular method of transmission in this epidemic, the impression has gained ground in certain quarters that we must revise our theories and our interpretation of facts regarding the transmission of this parasite, due to new and important data which were observed both epidemiologically and clinically during this outbreak.

As a matter of fact, in the opinion of the writer, no new essential epidemiological or clinical data have been secured as a result of the study of the Chicago epidemic, beyond the demonstration that cross-connections between water used for domestic purposes and polluted water supplies or sewers may act as very important sources of infection. While the Chicago epidemic was spectacular in its severity and the number of cases of amebic dysentery that resulted, the fact that water may be a transmitting agent is neither new nor has it been underestimated by students of amebiasis in

the past. However, some authorities, because of the epidemic mentioned, have recently endeavored to prove that water is the usual transmitting agent of this parasite and that other methods of transmission, especially that by food handlers, are negligible.

Water polluted with material containing *Endameba histolytica* has been recognized as an important method of transmission of amebiasis ever since the discovery of the etiological relationship of this parasite to amebic dysentery. Almost every writer and investigator has called attention to polluted water as a common method of transmission where the disposal of fecal material was not under sanitary control, so that the mere fact that water may transmit this infection was well known even before the discovery of the relationship of the cysts of *E. histolytica* to transmission. After the discovery of the cysts it was demonstrated by several investigators that these may live in water for a period varying from days to weeks, depending upon the amount of fecal pollution and conditions of temperature.

The writer has repeatedly urged the importance of a polluted water supply in the production of localized epidemics of amebic dysentery and has called attention to our experience in the

* Presented to the Pan American Medical Association, Sixth Annual Cruise, July, 1935.

Philippines during the Philippine Insurrection, as an example. During the time that our troops were engaged in active operations in the field amebic dysentery was very prevalent, occurring in veritable epidemics, and it was the consensus of all who studied these outbreaks that they were due to the drinking of polluted water from wells, springs, water courses, and local tanks, for when the troops returned to their permanent camps where there was a carefully guarded water supply and sanitary precautions regarding food handling were enforced, amebic dysentery soon ceased to be a factor of importance in the health records. That these local epidemics were not due to bacillary dysentery was conclusively demonstrated by laboratory observations, for bacillary dysentery was also prevalent among the troops in certain regions, and the distinction between the two forms was insisted upon by the authorities and made in the army laboratories.

Many years ago the writer and others called attention to the fact that under certain conditions, as the pollution of a water supply used by a large number of individuals, epidemics of amebic dysentery may occur, and while the possibility of such occurrence has been denied by certain protozoölogists upon the basis of purely biological inductions, the fact remains that such epidemics have occurred and will continue to do so when conditions favoring them are present. The Chicago epidemic of 1934 and the still later outbreaks in that city caused by drinking polluted water, described by Bundesen (1935), are merely the most recent examples of the epidemic occurrence of amebic dysentery when conditions are favorable.

The writer has no desire to minimize the importance of water as a transmitting agent of amebiasis, but in this

contribution it is desired to protest against a growing tendency to over-emphasize the importance of water and to minimize what should be regarded as a much more constant method of transmission, *i.e.*, the food handler who is excreting cysts of *E. histolytica* and who is careless in the observance of personal hygiene.

It is generally conceded that the most important methods of transmission of amebiasis are through a polluted water supply; by means of infected food handlers; through vegetables contaminated by polluted water or sewage; and by the droppings of flies or other insects that have fed upon material containing the cysts of this organism. Of these methods it is certain that the most important are transmission by polluted water and by infected food handlers and it is the relative importance of these two methods that will now be discussed.

There can be no doubt that where cross-connections exist between a domestic water supply and one unfit for domestic use because of sewage pollution, or cross-connections between a domestic supply and a sewer, there is always present a potential danger of infection with *E. histolytica* and that mass infection, severe in type, may occur in this manner. It is also true, that despite laws to the contrary such cross-connections exist in the older hotels and public buildings throughout the United States; but the fact that epidemics of amebic dysentery similar to the Chicago epidemic were unheard of before, is certainly proof that such cross-connections have not in the past been of very great importance in the transmission of amebiasis. To claim that this method of transmission is the most important one is not warranted by the evidence, for with the exception of that furnished by the Chicago epidemic, there is none which would indi-

cate that in a well sanitized city with a filtered water supply such a method of transmission is at all common or of great importance.

Under certain unusual conditions where raw polluted water is admitted to domestic supplies or where a large number of people drink a polluted water, as in the instances cited by Bundesen (1935), water may become a very important transmitting agent of amebiasis, but under usual conditions an unprejudiced student of the subject must admit that in cities and towns having a filtered water supply this method of transmission is not of prime importance.

It is in rural rather than in urban localities that water is probably a very common method of transmission. In such regions water for domestic use is usually obtained from wells or springs, and soil pollution with fecal material is of frequent occurrence. It is obvious that if such material containing cysts of *E. histolytica* is washed into the water supply it will result in the transmission of amebiasis by the water so contaminated, and no one can doubt that under such conditions this method of transmission is most important. However, even under these conditions one frequently finds that the person who prepares the food for the family is a carrier of the parasite, so that it is often impossible to evaluate the relative importance of transmission by water or through the handling of food by the infected individual.

Until quite recently all students of amebiasis have been convinced that the usual method of transmission of *E. histolytica* from man to man is by the infected food handler. The Chicago experience has led some authorities to doubt that this method of transmission is of frequent occurrence and some experimental work has been published which the authors believe demonstrates that transmission by food handlers is

the exception rather than the rule. Spector and Buky (1934) found that cysts of *E. histolytica* perished within 10 minutes when dried upon volunteers' hands grossly soiled with feces containing them, and these investigators conclude that the results of their experiments demonstrate that transmission by food handlers is not a very important source of infection. However, it should be remembered that even as short a period as 10 minutes is amply sufficient for a food handler to contaminate food if it is handled directly after the carrier leaves the toilet as very frequently happens, and Andrews (1934) has demonstrated that the cysts of this ameba may remain under the finger nails of unwashed hands in a viable condition for periods varying from 5 to 45 minutes and concludes that

The short survival period of *E. histolytica* cysts on the surface of fingers is no serious impediment to the acceptance of the proposition that food handlers may play a rôle of considerable importance in the dissemination of amebiasis.

This very conservative conclusion of Andrews is justified and, in the opinion of the writer, more than justified by epidemiologic and experimental evidence, for anyone who has had an extended experience with the epidemiology of amebiasis knows that transmission by food handlers is the usual method of transmission where there is a properly constructed public water supply.

Another contribution that has been used as an argument against the importance of food handlers in the transmission of this infection is that by Spector, Foster, and Glover (1935). These observers examined the hands of 74 carriers of *E. histolytica* immediately after passing their feces in the usual manner and found that 5, or 6.8 per cent, were positive for the cysts of this parasite. The hands were not washed

before the examinations were made. They conclude that the small percentage of the carriers whose hands were found positive for the cysts after defecation shows that contamination of food by food handlers who are carriers of this ameba must occur infrequently.

In the opinion of the writer the results of the observations of Spector, Foster, and Glover demonstrate the exact opposite of their conclusions. When it is remembered that in these 74 carriers only one examination after defecation was made and yet 6.8 per cent showed the cysts of *E. histolytica* upon their fingers, one is justified in believing that had from 4 to 6 such examinations been made, after as many defecations, a considerably larger number would have shown the presence of cysts upon their hands, so that their conclusion is not justified because of the small number of examinations that were made.

Furthermore, the fact that as many as 5, or 6.8 per cent, did show contamination of the hands by the cysts is sufficient proof of the importance of the infected food handler in the transmission of the disease. Certainly if in a survey of that number of infected food handlers 6.8 per cent of them, after a single defecation, showed contamination of their hands with cysts, it should be considered conclusive proof of the danger of the transmission of amebiasis by this class of individuals. It is obvious that the conclusion of these investigators that contamination of food by infected food handlers occurs infrequently is not justified, but that their results speak eloquently in favor of the importance of the food handler in the transmission of amebiasis.

The distribution of amebiasis among urban populations, as shown in numerous surveys made by competent observers, demonstrates that contamination of food by food handlers is the chief method of transmission of this

infection in such communities, and it has invariably been found that the incidence of infection in such populations is much higher among the ignorant and poor than among the more intelligent classes of the community. That this higher incidence cannot be due to transmission by water has been shown by the fact that the domestic water supply is the same for all classes and cross-connections in plumbing or other sources of water pollution, aside from contamination through food handlers, have not been demonstrated. In fact, the more prosperous classes in any urban community are much more apt to be exposed to infection from water pollution because of the greater frequency with which they eat in restaurants and hotels, where cross-connections in plumbing or back siphonage from a polluted into a safe water supply are much more apt to be present.

The higher incidence of infection with *E. histolytica* among the poor and less intelligent population of a city is believed by the writer to be almost entirely due to the contamination of the food prepared by someone in the household who is a carrier of this parasite. This is shown by numerous instances of familial infection in which a careful study has demonstrated beyond question the source of the infection.

Indeed, in these familial infections with *E. histolytica* we possess the indisputable proof of the importance of the food handler in the transmission of amebiasis, and such familial infections, although much more numerous among the lower classes of our urban populations, are by no means confined to such classes, for the writer has records of many families among the well-to-do and educated in which several members were infected from cooks who were carriers of *E. histolytica*, and where any possible source of water transmission except that furnished by

the food handler could be absolutely eliminated.

As an illustration of this type of familial infection the following may be cited:

The family of a high-ranking officer of the United States Army, consisting of 8 members, and residing in an army post just outside Washington, D. C., was examined by the writer for infection with *E. histolytica* owing to the fact that the officer had consulted him regarding attacks of slight diarrhea which had occurred at irregular intervals for about a year. Examination in his case disclosed an infection with this parasite and examinations of the remaining 7 members of his family resulted in showing that 4 others had a latent infection with this ameba, i.e., 62.5 per cent of the family showed infection. The cook in this family was a Filipino boy who had worked for them for over a year and an examination showed that he was a carrier of *E. histolytica*. The water used for all purposes was from an impounded and filtered supply furnished the entire post, and the plumbing in the dwelling occupied by the family was in perfect condition with no possibility of pollution by cross-connections or back siphonage. No other cases of amebic diarrhea or dysentery were reported in the post during the time that these examinations were made. The treatment of the infected members of the family and the cook resulted in the disappearance of the infection, and no further infections occurred in this family, although they were all examined at regular intervals over a period of 1 year.

Another instance, personally observed by the writer, in which water directly contaminated by a carrier was the source of infection may be cited:

In an office where 5 individuals were employed there developed in 1 an acute attack of amebic dysentery, and an examination of the other employees demonstrated infection with *E. histolytica* in 2 others, proving that 3, or 60 per cent, of the personnel were infected with this parasite. A study of the local situation resulted in demonstrating that 1 of the infected individuals cared for the water cooler, cleaning it each morning and handling the ice with which it was supplied. The 2 others who were infected were in the habit of drinking large quantities of water from this cooler each day, while the 2 members of the office personnel who escaped

infection never drank water from the cooler but from the faucet of the general water supply of the building in which the office was located. Several hundred people were employed in this building and there was no case of amebic diarrhea or dysentery reported during the time that these infections occurred.

These clear-cut examples of contamination of food and water by handling should alone be sufficient to demonstrate the great danger of the transmission of amebiasis by infected food handlers, but such examples in the experience of the writer can be multiplied many times. As he has stated elsewhere (1935)—

The contamination of food and drink by food handlers, who are passing the cysts of *E. histolytica*, the so-called "carriers," is undoubtedly the most common and most important method of transmission in many localities and certainly so in towns and cities having an impounded water supply and where sanitation is otherwise excellent. Food handlers in our hotels, restaurants, lunch counters, roadside refreshment stands, and other places where food is handled and sold, are the chief sources of amebic infection in well sanitized towns and cities in the United States, and it may be stated that the contamination of food and drink handled by infected food handlers is practically a certainty unless the greatest care is taken regarding personal hygiene and the cleanliness of the hands of those who handle the food. One has only to watch the average salad maker in the average hotel or restaurant to understand how uncooked food may become infected, for each separate leaf of lettuce and each slice of tomato or other vegetable or fruit is actually handled in arranging the salad and making it appear attractive. Cooks and mess attendants, salad makers, bread boys, and even waiters, are often very efficient transmitters of amebiasis.

In conclusion, it may be stated that the evidence available demonstrates that water as a method of transmission of amebiasis ranks second in importance to contamination of food by food handlers who are carriers of *E. histolytica*; that both methods of transmission should be most carefully

guarded against and controlled, if possible; but that efforts to minimize the danger of transmission by food handlers are to be deplored and will result in increasing the already high incidence of an important disease producing parasite of man.

Safe Toys

. . . In the last year alone 15,400 children under 15 years of age died as the result of accidents, and 13,500 more young men and women 15 to 24 years of age were killed by accidents—a total of 29,000. And that, more or less, is what happens year after year. . . .

The country has told us over and over again that in 30 years we have killed and injured more people by using fireworks to celebrate the acquisition of our independence than were killed in acquiring that independence in the Revolutionary War. . . .

A study is being made by the American Museum of Safety, with the coöperation of the National Society for the Prevention of Blindness and other public health agencies. The study was financed by the fireworks manufacturers, themselves, who are at last beginning to realize the gravity of the situation. . . . There are in hand reports of more than a score of persons who were killed and more than 6,000 who were injured as a result of the celebration of the past Fourth of July with fireworks, firearms and bonfires.

You may ask, why bring these unpleasant facts to an audience of school teachers? The answer is that school teachers probably have a greater opportunity than any other group to

influence safe conduct among school children. . . .

School teachers have not only a responsibility for the prevention of accidents on school property, but have an extraordinary opportunity to help children acquire safe habits without at the same time losing the zest for life and adventure. . . .

The records of the National Society for the Prevention of Blindness tell the story of scores of children who lose the sight of one or both eyes each year as the result of shots from air rifles, gifts from fond parents. . . .

We are getting the coöperation not only of the fireworks manufacturers, but of toy manufacturers, in our efforts to make playthings less hazardous, but the time is still far off when we may assume that a toy is safe for a child because its manufacturer or the merchant who sells it says it is. . . .

How to bring safety education to the parents and guardians of these children is the task of all of us—the National Safety Council, the National Society for the Prevention of Blindness, the many other public health agencies in the country, and the public schools as well. . . .—From address by Lewis H. Carris at a meeting of the Child Education Section of the National Safety Congress, Louisville, Ky., Oct. 14, 1935.

Need for Health Instruction in Cleanliness

HUGH GRANT ROWELL, M.D., AND JAMES A. TOBEY,
DR.P.H., F.A.P.H.A. (*Life Member*)

*Professor of Health Education, Teachers College, Columbia University, New York,
N. Y.; President, Westchester Tuberculosis and Public Health
Association, Inc., White Plains, N. Y.*

IT is no exaggeration to state that, broadly interpreted, modern civilization depends for its existence upon cleanliness. Progressive communities have recognized this fact and have provided their citizens with pure water supplies and safe methods of sewage and waste disposal. As a consequence of these ventures in municipal housecleaning, the former high incidence of certain water-borne and filth-borne diseases has been greatly reduced. Typhoid fever, for example, caused nearly 36 deaths per 100,000 population in the United States in 1900, whereas in 1928 it was responsible for less than 5 deaths per 100,000, and in 1934 23 of our largest cities had no deaths at all from this once ubiquitous scourge.

Diseases due to lack of cleanliness have been reduced, but by no means eradicated. This is because environmental sanitation, no matter how highly developed, is only one of the many factors in health protection. Personal hygiene, as applied to all life situations, is as important in disease prevention as is public sanitation, but for one reason or another individual hygiene in this country seems to be much less advanced than is community hygiene.

responsibility that lies in the laps of our educational authorities. The school takes the child in his impressionable years, gives him knowledge, and teaches him the alphabet of life. It endeavors to inculcate in him proper habits of living, including the way to health through good nutrition and general hygiene. Sometimes, but not always, it furnishes him with an environment that is conducive to good health.

When the school performs these functions adequately and satisfactorily, its influence extends far beyond its own confines, for the school child carries the message of good health into the home. The pupil who has learned that a quart of pure milk a day will give him healthful growth, that this milk ought to be pasteurized, that he must wash his hands before each meal and after leaving the toilet, and that soap has a definitely useful purpose, will contribute these and other necessary hygienic precepts to the entire family, the members of which will be benefitted thereby.

In its health instruction, the school operates best by action rather than by words. Thus, lectures and discourses are much less valuable and effective in teaching good health practices than are actual performances by the children

THE RÔLE OF THE SCHOOL

The correction of this situation is a

themselves and by their teachers. A student may learn and recite glibly that moving air at a temperature of 68° F. is most desirable for health, and yet, as frequently happens, the temperature of his own classroom may be maintained routinely at the enervating figure of 74° F.

Similarly, the child may be instructed to wash his hands with soap and water after using the toilet and before lunch, but the school may have neglected to provide soap and towels, and even water, or at least hot water, for this laudable purpose. He may be told that cleanliness is next to godliness, but may have inadequate facilities for bathing at home and none at school, even after participating in athletics and other desirable physical exercise. Physical education is part of the curriculum in most modern schools, but many of them fail to furnish shower baths to remove the perspiration and grime that usually accumulate when children indulge in organized exercise and play.

FACILITIES FOR CLEANLINESS IN SCHOOLS

Extensive surveys of handwashing equipment in schools have revealed that in the majority of our educational institutions the necessary combinations of hot water, soap, and individual towels, conveniently located and in sufficient quantities, are seldom available. Thus, in 1928 it was found from an investigation of 404 schools located in 22 states and the Dominion of Canada, that in only 53.2 per cent of the buildings was hot water supplied, in 80 per cent was some form of soap furnished, and in 84.1 per cent were towels available.

When, moreover, complete and adequate hand-washing facilities were considered, only 32 per cent of these schools could comply with the American Child Health Association's reason-

able standards of one lavatory to every 80 pupils, equipped with all three of the necessities for proper ablutions. Only 19.3 per cent of these same schools conformed to the more stringent school health requirements of the Massachusetts Institute of Technology, specifying at least one well equipped lavatory for every 40 pupils, while only 5.7 per cent of them were within the Wood-Rowell standards of at least one lavatory, with hot water, soap, and towels conveniently located, to every 20 pupils.¹

Another investigation conducted a few years later in 145 schools in 15 states showed that about 99 per cent furnished water, but only about 74 per cent provided hot water; that only 57 per cent supplied soap for general hand-washing; that only about 70 per cent had drying equipment; and, finally, that a mere 31 per cent had all three of these necessary facilities together.²

Not only was there a distressing lack of cleanliness equipment in two-thirds of these schools, but in most cases the supplies provided were insufficient for the best results, or were not available throughout the year. The average expenditure for soap per child was estimated to be only about half what it should have been in order to permit each pupil to wash his hands twice a day, a reasonable minimum and far less than any average adult would find acceptable.

The quality of the soap employed in these schools, whether cake, powdered, liquid, or flake, frequently was not well adapted for its purpose or the device was out of order, or out of soap. The efficiency of soap is influenced by the chemical nature of the water available, and also by the purity and composition of the soap itself. A poor grade of soap which has low solubility in a particular water supply, greatly increases the time element required for handwashing and reduces

the efficiency of the process. Poor soaps may also cause irritation of the skin. For these reasons, soap obtained for personal cleanliness in schools should be pure, in the commercial sense, and carefully selected with regard to local conditions. The school janitor is not always an expert with respect to the chemical nature of water and the choice of soap needed to cope with the local supply. The selection of proper soaps has not been brought adequately to the attention of school authorities. Price is only one factor, since cheap soaps, or wrongly selected ones are often the most costly. The traveller in Europe becomes most emphatic on this point following experience with native soaps there.

PURITY STANDARDS OF SOAP

Since the purpose of hand-washing is hygienic as well as esthetic, and since the process, by removing dangerous microorganisms along with dirt, should be a real factor in preventing the spread of communicable diseases, the purity standards of the soaps used in school lavatories are of considerable significance. School administrators should, therefore, have a clear understanding of the germicidal powers of various soaps.

When the human body is involved, the criteria of effectiveness of cleansing agents must be their success in removing dirt, odors, and bacteria; their efficiency in destroying or nullifying the toxic effects of these microorganisms; and, finally, the condition of the human body, chiefly the skin, when the cleansing process has been brought to a successful conclusion.

Chemically, soaps are combinations of strong alkalis, such as sodium and potassium, with weak acids, mainly the fatty acids. They are alkaline products of varying alkalinity, the sodium soaps being generally known as "hard," and the potassium soaps as "soft." A

"pure" soap in the commercial sense is one made from high quality fat and possessed of a relatively small amount of free alkali which is an irritant to tender skins and may also cause trouble when the average skin is exposed to it over a long period.

The germicidal properties of soaps have been scientifically studied by a number of competent investigators. It has been demonstrated that pure soaps are highly germicidal against such dangerous organisms as streptococci, pneumococci, meningococci, influenza bacilli, and *Spirocheta pallida*.³ In other words, ablution with pure soaps aids in reducing the hazards of possible transmission of various respiratory diseases, and of syphilis, if the germs causing these maladies happen to be present on the hands. Soap has likewise been found to be a valuable prophylactic in Vincent's angina.⁴

The use of hot water with soap adds to its germicidal efficacy, part of the effect being due to the heat. Of course, however, the bactericidal action of soap is selective, since the use of pure soap is of little value against such highly resistant organisms as the typhoid bacillus and the staphylococcus, although certain types of specially prepared laboratory soaps will destroy even these bacteria. In this connection it is well to remember that a medicinal odor adds nothing to the cleansing or germicidal value of soap.

In a recently published review of the germicidal value of pure soap, a well known dermatologist reaches the conclusion: "Soaps are potent factors in preventing the spread of disease not only on account of their germicidal action on the common organisms . . . but also because no antiseptic can replace cleanliness."⁵ This authority also points out that soap is the most practical disinfectant for everyday life, to be supplemented when the occasion arises by surgical antiseptics prescribed

by physicians, and he also states that pure soap is superior to other types of soap in its germicidal powers.

THE DUTY OF EDUCATIONAL AUTHORITIES

From these facts it is obvious that hand-washing in schools, in industry, and in the home is a prophylactic measure of real hygienic significance. It is the important duty of all school physicians and nurses to recommend most strongly that adequate sanitary facilities and equipment for this purpose be installed where they are lacking, and it is the duty of educational authorities to provide ample means for the carrying out of this salutary practice. If they fail to do so, the parent, as the voter and tax payer, should be heard from. The function of the teacher, as the individual who is primarily responsible for health education in the classroom, is to insist that hand-washing with hot water and pure soap be a routine procedure by all pupils, especially after leaving the toilet and before eating.

The more extensive application of these and other hygienic principles among the 26 million school children of this country will result in a gratifying decline in the incidence of certain types of disease, commonest causes of absenteeism, and by its favorable effect upon school health and upon public health generally, will help to promote a more vigorous and salubrious American citizenry. In these days, when homes must frequently put up with deprivations and economies of relief or wrecked budgets, the school must be able to offer a proper balance in cleanliness, as in other health practices, for the ideals and ideas of growing Americans.

A Study of *B. coli mutabile* from an Outbreak of Diarrhea in the New-born*

ANNA DEAN DULANEY, PH.D., AND I. D. MICHELSON, M.D.

Medical School, University of Tennessee, Memphis, Tenn.

DURING the winter of 1933-1934 a succession of cases of a hitherto unrecognized diarrhea occurred among the new-born in the Memphis General Hospital. Forty-seven per cent of the infants affected died.

The disease made its appearance on the 5th to the 9th day of life, and there was no relation to sex, race, prenatal history, or state of nutrition. Since the outbreak occurred during the height of the economic depression, the lack of correlation with the nutritional state is worthy of notice.

The onset of illness was characterized by an elevation of temperature or marked loss of weight occurring within 24 hours. This was followed by a diarrhea which increased in intensity until the stools numbered 10 to 20 per day. The stools were watery, yellowish or yellowish green of color and, surprisingly, free from blood, pus, or mucus.

Vomiting usually followed the feedings, the vomitus consisting of curds of yellowish, partially digested food. Dehydration, septicemia, otitis media, and alkalosis were complicating factors. In cases ending fatally, the infants became cyanotic, respiration was rapid

and shallow, and the eyes were sunken.

The physical findings were essentially negative. No medication seemed effective, and in 4 to 9 days the babies either died or gradually improved.

At necropsy the positive findings were dehydration, acute cloudy swelling of the visceral organs, otitis media, and, in several cases, bronchopneumonia. The intestinal tract was negative on gross and microscopic examination.

Extensive bacteriological studies were carried out in the hope of determining the causative agent. Cultures were made from feces, urine, blood; and nose, throat, and ear discharges of the sick babies. Five autopsies were performed and blood, exudates, and swabs from the visceral organs were inoculated to suitable media. The feedings were repeatedly cultured, as were swabs from the nipples of the bottles in order to detect food or hand contaminations. The throat and fecal flora of the mothers and attending nurses were studied. With the possible exception of the fecal cultures the findings were varied and inconsistent, and permitted no conclusions as to a specific causative agent.

Blood cultures from 10 of the babies yielded *B. coli*, *Staphylococcus albus*,

* Read before the Laboratory Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

and pneumococci, with *B. coli* as the organism of highest incidence. The possibilities of terminal invasion and skin contamination were recognized. *B. coli* and *Staphylococcus albus* were obtained from the urine cultures; *B. coli*, streptococci, staphylococci, pneumococci from nose and throat swabbings; and staphylococci, *B. coli* and pneumococci from cultures from the ear. *B. coli* was the most common organism found in middle ear infections. The most significant bacteriologic findings at autopsy were the frequent isolations of *B. coli*, and these results will be discussed later.

Repeated culturing of the yellowish watery stools consistently yielded slow lactose fermenting bacilli which proved to be *B. coli mutabile* in a high percentage of cases, and the study of these cultures instigated this report.

METHOD OF EXAMINATION OF FECES AND FINDINGS

The specimens of feces from all babies were obtained by introducing a sterile proctoscope and swabbing the rectum. The swabs were immediately washed off in tubes containing 2 c.c. of sterile physiological saline. Smears were stained by Gram's method. As a rule, the smears showed a mixture of organisms—*B. bifidus*, enterococci, Gram-negative bacilli, etc. The stools of normal breast fed babies contained *B. bifidus* as the predominating organism, over 90 per cent of the organisms were of this type, while the stools of healthy babies artificially fed showed a high proportion of Gram-negative bacilli. Regardless of the type of feeding, the stools of babies suffering from diarrhea gave a high percentage of Gram-negative bacilli, with Gram-positive organisms present in small numbers. The Gram-negative bacilli in the diarrheal stools were single or paired, with rounded ends.

Serial dilutions of the initial fecal

suspensions were made so that the last tube was water clear. The three highest dilutions were spread on dry Endo's plates, by bent glass rods. Fecal suspensions from sick babies were also inoculated on blood, and plain agar plates, brain medium, and nutrient broth. All cultures were made in duplicate and grown under aerobic and anaerobic conditions.

The Endo's plates showed the most interesting and significant results. Three chief types of colonies were observed—typical *B. coli* colonies, flat and metallic; small pin-point colonies which proved to be enterococci; and colorless colonies characteristic of the typhoid-dysentery group. The colorless colonies, which when present outnumbered the other types on all Endo's plates, were opalescent, regular in outline, raised, typically smooth, and measured 1 to 2 mm. in diameter. When transplanted to Russell's double sugar a paratyphoid reaction was obtained with active production of acid and gas in the butt and no change in the slant. After 2-3 days at room temperature, secondary colonies appeared on the slant; these were raised, yellowish, circumscribed elevations in the midst of the mass growth. When dilute suspensions of 24 hour cultures on Russell's double sugar were spread on Endo's plates, only colorless non-lactose fermenting colonies were obtained. Within 48 to 72 hours a number of these originally colorless colonies developed red metallic papillæ. We then recognized the organism as *B. coli mutabile* and were able to demonstrate the cycle of colony form described by Neisser (1906)¹ and Massini (1907).²

Transplants were made to Russell's double sugar and plain agar, and stored while we made the examinations of feces of healthy and diseased adults. Specimens of stools were collected on sterile swabs, a saline suspension was

made, and spread on Endo's plates. These plates were observed for non-lactose fermenting colonies and subcultures were made.

INCIDENCE

The stools of 27 sick babies were cultured and in 18 (67 per cent) *B. coli mutabile* organisms were present in large numbers. As shown in Table I, we also cultured the stools of 41

ganism. Of 43 parturition patients 9 (21 per cent) showed slow lactose fermenting bacilli, 3 (5 per cent) of which were *B. coli mutabile*.

It is seen that slow lactose fermenting Gram-negative bacilli are increased in pathologic conditions in which diarrhea is a part of the picture, an observation frequently reported. While 32 per cent of sick adults showed such organisms in their stools, the inci-

TABLE I

SHOWING THE INCIDENCE OF *B. COLI MUTABILE* IN THE STOOLS OF 186 DISEASED AND NORMAL BABIES AND ADULTS

Group	Number	Slow Lactose Fermenting Gram-negative Bacilli	<i>B. coli mutabile</i> Present	Negative for Both
Sick babies	27	18 (67%)	18 (67%)	9 (33%)
Normal babies	41	5 (12%)	5 (12%)	36 (88%)
Normal adults	47	5 (10%)	1 (2%)	42 (90%)
Sick adults	28	9 (32%)	2 (7%)	19 (68%)
Parturition	43	9 (21%)	3 (7%)	34 (79%)

normal babies and of 118 healthy and diseased adults to ascertain the frequency of this organism and other slow lactose fermenters in normal and pathological conditions of the gastrointestinal tract. Of 21 normal babies, studied at the time of the epidemic, we isolated *B. coli mutabile* from the stools of 5 (24 per cent). Six months later, when the outbreak of diarrhea had entirely subsided, we examined the stools of 20 other normal babies and did not find this organism in any specimen. Five (10 per cent) of the stools from 47 normal individuals were positive for slow lactose fermenting Gram-negative bacilli, and 1 (2 per cent) proved to be *B. coli mutabile*. Examination of the stools of 28 adults suffering from diseases in which diarrhea may be an outstanding symptom (typhoid fever, dysentery, food poisoning) yielded 9 strains of slow lactose fermenting Gram-negative bacilli, 2 (7 per cent) of which fulfilled the cyclic criteria of this "mutabile" or-

dence of slow lactose fermenting Gram-negative bacilli in the stools of babies suffering with diarrhea increased to more than twice this figure. All of these organisms proved to be *B. coli mutabile*. Kriebel³ has reviewed the literature on this question and described such organisms which she isolated from food handlers and persons suffering from diarrhea and vomiting of unknown origin. We made no attempt to classify these miscellaneous slow lactose fermenting bacilli and only studied the organisms which were typical *B. coli mutabile*. The incidence of these unidentified slow lactose fermenting Gram-negative bacilli was increased in the parturition group.

Autopsy cultures yielded a variety of organisms. *B. coli mutabile* was found in 3 of the 5 cases; in 2 this organism was recovered from the heart blood, spleen, ileum, jejunum, colon, and middle ears. In each case in which a pure culture of *B. coli muta-*

bile was obtained from one ear, cultures from the other ear showed a mixed flora.

While we are reluctant to assign a fixed etiological rôle to this organism, the high percentage of isolations from the stools of infants showing diarrhea, the low incidence in stools of normal babies and normal and sick adults is regarded as highly significant. Additional evidence is offered by the absence of gross and microscopic changes in the intestinal tract and the isolation of this organism from secondary foci of infection at autopsy. Finally, the cultural and serological relationship found to exist among these organisms affords the best bacteriologic evidence of their possible etiological rôle.

OBSERVATIONS ON *B. COLI* MUTABILE IN RELATION TO LACTOSE

Suspensions from the edge of the colorless mother colony when spread on Endo's plates gave rise to 100 per cent colorless colonies. Within 3 days, approximately one-fourth of these colonies had developed red metallic papillæ, and after 10 days all showed this phenomenon. In most cases, the earliest papillæ appeared near the center of the colony. Papillæ usually developed 1 to 2 days earlier at incubator than at room temperature, but the final number was not different.

When a saline suspension of these metallic papillæ was spread on Endo's agar, both red and white colonies developed. The red typical *B. coli* type predominated; as a rule, less than a third of the colonies were colorless. The white colony showed the S characteristics; the red colony was flat and granular and suggestive of the R type. The lactose fermenting colon-like colony bred true while the colorless non-lactose fermenting colony reproduced the mutabile cycle.

It was thus possible to obtain a

red strain which was stable and a white strain which was unstable in that it continued to give rise to some red descendants. We have designated the lactose fermenting organisms as "red" and the non-lactose fermenting organisms as "white," unless otherwise indicated. All efforts to obtain a stable white strain have failed. We tried repeated platings of both young and old colonies—reasoning that very young colonies might be expected to yield only white descendants before red variants had been given off in response to the lactose stimulation, and that variation in old colonies would not occur after active cell division had ceased, but all white colonies, young or old, have continued to yield red papillæ on Endo's plates and apparently all non-lactose fermenting cells are able to give rise to lactose fermenting descendants under the stimulus provided by the lactose. We also tried plating after storage on plain agar, but so far have obtained no stable non-lactose fermenting cultures.

Transplanting of the white strain to Russell's double sugar medium at intervals of 1 or 2 days maintained the paratyphoid-like reaction. If transplantation were delayed for 10 to 14 days, until numerous secondary colonies had developed, a typical colon reaction was produced on the Russell's agar.

Serial passage of the white strain in lactose broth speeded up the rate of lactose utilization. Four to 7 days were initially required for production of acid and gas in 1 per cent lactose broth, but after 7 to 10 passages at 24 hour intervals, it occurred in 48 hours. This is in accordance with the findings of Jones,⁴ Kennedy,⁵ Kriebel,³ and others on atypical colon bacilli.

The utilization of lactose was also influenced by the type of culture container. Kennedy⁵ states that his slow lactose fermenting organisms broke down lactose more rapidly when grown

in toxin flasks, and we found this to be true. For example, 1 per cent lactose broth of pH 7.4 with bromthymol-blue as an indicator was distributed in 40 c.c. amounts in the following types of containers: 1,000, 250, 125, and 50 c.c. flasks, and a large test tube 200 x 25 mm. A regulation test tube, 120 x 18 mm., containing 20 c.c. of broth served as a control.

All containers received the same inoculum of white organisms prepared by scraping off a single non-lactose fermenting colony from an Endo's plate inoculated 15 hours previously, and suspending the growth in sterile saline. Whereas the indicator showed an acid reaction greater than pH 6.1 in the 3 larger containers by the end of 48 hours, the 50 c.c. flask and the 2 tubes were still neutral. After 72 hours the organisms growing in the 50 c.c. flask had produced sufficient acid to change the color of the broth to yellow while the 2 tubes remained unchanged until 96 hours had elapsed.

When samples from the various sized containers were withdrawn at intervals and spread on Endo's plates the findings varied. The original inoculum and 24 hour samples from all containers yielded only non-lactose fermenting colonies and produced a typical paratyphoid reaction on Russell's double sugar. After 72 hours, samples from the tubes still gave only non-lactose fermenting colonies while Endo's plates inoculated from all 3 flasks showed both red and white colonies. A typical colon reaction was produced on Russell's double sugar. Thus the utilization of lactose was shown to be a result of dissociation; of the production of a sufficient number of red variants to break down lactose, rather than an acquired or latent use of this sugar by the white organisms. It is doubtful if the white forms can ever utilize lactose, but under the stimulus provided by this

sugar lactose splitting descendants are produced with the resultant acid and gas.

Jones *et al.*,⁴ offer data to show that apparently slow fermentation of lactose by certain strains of *B. coli* is in reality due to production of sufficient ammonia in the early hours of growth to neutralize the acid formed from the beginning. Nungester and Anderson⁶ have described a series of variants derived from a colon-like bacillus. Some of these variants produced non-lactose fermenting colonies on Andrade's indicator agar but when grown in lactose broth reversion to lactose fermenting forms took place. Kriebel³ also states that cultivation of Gram-negative non-lactose fermenting intestinal bacilli in 5 per cent lactose solution stimulated dissociation into lactose fermenting variants.

This dissociation of white to red was correlated with the utilization of lactose. Nutrient broth of pH 7.4 was prepared and 300 c.c. placed in each of 2 flasks of 500 c.c. capacity. Ten per cent lactose solution which has been separately sterilized was added to the broth to give a final concentration of 1 per cent. A single non-lactose fermenting colony from an Endo's plate which had been inoculated with the Garrett strain 15 hours previously was suspended in saline and 1 flask of broth inoculated. The other flask received a comparable inoculum of a lactose fermenting colony of the Garrett strain taken from an Endo-plate inoculated with the red form at the same time. Samples were taken immediately after inoculation; part was diluted and used for streaking of dry Endo's plates, the remainder for the quantitative determination of lactose. This procedure was repeated after 8, 19½, 25, 31, 41, 48, and 96 hours' incubation. All plates from the flask containing the culture of white organisms up to the 31 hour period:

yielded only white or non-lactose fermenting colonies. The plates inoculated with dilutions of the 31 hour sample were the first to show lactose fermenting organisms. Twelve per cent of these colonies were red metallic colon-like. The plates inoculated with dilutions of the sample taken after 41 hours' incubation gave approximately an equal number of red and white colonies while the plates from the 48 hour sample showed a 75 per cent red and 25 per cent white distribution. After 96 hours, 90 per cent of the colonies were red.

TABLE II

EFFECT OF LACTOSE ON DEVELOPMENT OF RED FORMS

<i>Hours After Inoculation</i>	<i>Percentage of Colonies on Endo's Plates</i>	
	<i>White</i>	<i>Red</i>
0	100	0
8	100	0
19½	100	0
25	100	0
31	88	12
41	50	50
48	25	75
96	10	90

The plates from the flasks inoculated with the red form consistently yielded only red lactose fermenting colonies. Details of the utilization of lactose are not included here, but while the red form actively broke down lactose from the beginning, the white form did not show definite evidence of using this sugar until 31 hours had elapsed. In other words, utilization of lactose is coincident with the appearance of red variants and lactose apparently has a stimulating effect on the production of such forms, a conclusion reached by early workers. Lewis⁷ has recently disputed this conclusion and maintains that variation occurs under any condition suitable for growth. In support of this statement he offers data obtained from plating out cultures

grown in various media. He was always able to demonstrate some variant cells, recognized on the basis of size, in colonies grown on any medium by means of densely seeded agar plates. According to him, sugars and alcohols serve as selective agents but do not specifically incite variation. We cannot agree with this since we have not been able to demonstrate the development of lactose fermenting organisms in plain broth or broth containing other sugars than lactose.

When flasks of the same size and containing equal amounts of 1 per cent lactose, 1 per cent dextrose, and plain broths received the same inoculum of white organisms and were grown under the same conditions, dissociation to the red form occurred only in the presence of lactose. Endo's plates streaked from samples of the dextrose and plain broth at intervals over a 5 day period initially gave rise to only white colonies. These in time showed lactose fermenting papillæ. With the exception of one culture in 1 per cent sucrose broth, Nungester⁶ was not able to effect reversion of his non-lactose fermenting variant to the lactose fermenting form in any medium other than lactose broth.

Daily transfer for 10 days in 1 per cent dextrose, maltose, saccharose, mannite, broths did not alter the picture when these cultures were subcultured to Endo's plates.

It was also found that the time of coming into contact with the stimulating effect of lactose did not greatly influence the end results. Equal quantities of a suspension of Garrett white organisms were introduced into 2 flasks, one containing 100 c.c. of plain broth and the other 100 c.c. of 1 per cent lactose broth. Conditions of growth were the same. After 24 hours samples from both flasks gave rise only to non-lactose fermenting colonies. After 48 hours the plating from the

lactose broth culture showed that dissociation had taken place and approximately 20 per cent of the colonies were red. The sample from the plain broth yielded only non-lactose fermenting colonies. After the 48 hour sample had been withdrawn from the plain broth culture, sufficient 10 per cent lactose was added to give a final concentration of 1 per cent and the flasks returned to the incubator. After an additional incubation period of 48 hours Endo's plates were spread with samples from the two flasks. A comparable distribution of red and white forms appeared—approximately 90 per cent of the colonies on both plates were of the red lactose fermenting variety. We had thought that late contact with the lactose might not incite variation.

CULTURAL REACTION

Nungester⁶ points out that any conclusions regarding fermentation of carbohydrates in liquid mediums by variants of a series must take into consideration the possibilities of variation occurring during the period of observation. He found that certain of his variants differed in their ability to use sugars (maltose and lactose) when grown in liquid and solid mediums containing the same concentration of these carbohydrates. Platings from the culture grown in lactose broth gave rise to a mixture of non-lactose and lactose fermenting colonies.

As previously stated, we repeatedly demonstrated that fermentation of lactose by the white forms of our *B. coli mutabile* strains was brought about by the lactose fermenting forms which developed in response to the stimulus afforded by the sugar.

We also found that apparently slow fermentations of salicin and raffinose were in reality dissociation phenomena with the production of organisms capable of utilizing these

sugars in a highly specific fashion.

Rapid fermentation of sugars was never accompanied by any dissociative process. All strains of *B. coli mutabile*—both white and red—produced acid and gas within 18 hours when grown in broths containing the following sugars in 1 per cent concentration—dextrose, maltose, mannite, saccharose, xylose, arabinose, sorbite, rhamnose, levulose. Equally active fermentation was demonstrated on sodium-sulphite-fuchsin agar (3 per cent) containing the same concentration of these sugars—only red metallic colonies forming. Apparently all organisms readily attacked these sugars.

All strains of *B. coli mutabile*—both lactose red and white—failed to break down inosite, melizitose, cellobiose and adonite after 14 days incubation.

Dulcitol, salicin, and raffinose were irregularly fermented. All strains except 1 (Shea white) fermented dulcitol within 5 days; all strains—both red and white—fermented salicin within 5 days. All 18 red forms produced acid and gas in raffinose broth in 3 to 4 days, but 8 corresponding white forms (Shea, Whitney, Lee, Russell, Byrd, Phillips, Garrett, Rimmer) failed to produce any change in this medium even after 14 to 20 days incubation.

These inconsistent results led us to study the reactions of 2 of our strains, Rimmer and Garrett, toward these sugars under conditions of liquid and solid media. Nutrient broth and sodium-sulphite-fuchsin agar (3 per cent) containing 1 per cent amounts of dulcitol, salicin, and raffinose were prepared. These media were inoculated at the same time with suspensions of Rimmer, red and white, and Garrett, red and white. The inoculums were prepared by scraping off isolated colonies from Endo's plates, inoculated the previous day, and suspending the

TABLE III

Strain	Dulcitol		Salicin		Raffinose	
	Broth	Agar	Broth	Agar	Broth	Agar
Garrett White	A.G.-4 da.	Colorless colonies in all cases. No metallic papillæ. Sub-cultures from broth yielded only colorless colonies.	*A.G.-3 da.	Originally colorless colonies all of which gave rise to metallic papillæ in 4 days	Neg.-20 da.	Only colorless colonies; no metallic papillæ
Garrett Red	A.G.-3 da.		*A.G.-3 da.		*A.G.-4 da.	Colorless colonies with metallic papillæ 2 days
Rimmer White	A.G.-3 da.		*A.G.-3 da.		Neg.-20 da.	Only colorless colonies; no metallic papillæ
Rimmer Red	A.G.-3 da.		*A.G.-3 da.		*A.G.-5 da.	Colorless colonies with metallic papillæ 4 days

* Sub-cultures to agar produced both white and red colonies.

growth in a small amount of saline. A summary of these results is given in Table III.

Dulcitol agar plates inoculated with these four organisms, Garrett, white and red, Rimmer, white and red, showed only colorless colonies. Even after 5 days there was no change in the general appearance nor had metallic papillæ developed. Dulcitol broth, however, was fermented by all 4 organisms in 3 to 4 days but when these cultures were spread on dulcitol agar plates only colorless non-dulcitol fermenting colonies developed. Apparently, dulcitol affords an example of true slow fermentation.

Salicin agar plates inoculated with the 4 organisms originally yielded only colorless colonies. After 4 days all colonies were studded with metallic papillæ. The salicin broth was broken

down in 3 days and when these cultures were spread on salicin sodium-sulphite-fuchsin agar, both white and red colonies appeared. Here we have an example of true dissociation with salicin red forms developing in liquid and solid medium in response to the stimulus afforded by the sugar.

In the case of raffinose we demonstrated a third type of reaction. Raffinose broth was not fermented by either Garrett, white, or Rimmer, white, even after 20 days, but both Garrett, red, and Rimmer, red, formed acid and gas in 4 to 5 days. When these red cultures were spread on raffinose agar both white and red colonies were demonstrated. Inoculation of the raffinose agar plates from the original inoculum produced colorless colonies. After 2 days Garrett red colonies showed many metallic

papillæ and after 4 days the Rimmer red colonies had also developed metallic papillæ. In this case we have an example of specialized fermentation of raffinose by the lactose red organisms due to the production of raffinose red descendants.

We plan to extend these studies to other strains. It is possible that we may be able to demonstrate dissociation to dulcitate, and since some of the white forms did ferment raffinose we would expect to obtain both white and red colonies on raffinose agar upon sub-culture.

In no case was the reaction of these organisms toward lactose altered. Salicin, red and white, and raffinose, red and white, organisms when sub-cultured to Endo's plates produced colonies characteristic of the original type. In other words, variation to lactose was not altered by contact with other sugars.

It seems possible that such a dissociation phenomenon may often occur and that slow fermentation of sugars should be investigated from this standpoint. It is not unlikely that certain difficulties in classification of some of these intestinal organisms could thus be eliminated.

An acidity developing in 2 to 4 days with the production of curds characterized the growth of all strains in litmus milk; no peptonization occurred.

Indol was formed in Dunham's peptone broth by the red and white forms of all strains.

Nitrates were reduced to nitrites and ammonia formed in nitrate broth. The methyl red reaction was positive, the Voges-Proskauer reaction negative.

Gelatin was not liquefied after 14 days.

AGGLUTINATION TESTS

Agglutination tests were carried out with the sera of 43 patients—5 sick babies, 13 healthy babies, 13 mothers, 10 sick adults, and 2 normal adults. For antigens we used heat killed saline suspensions of *B. coli mutabile*, Rimmer and Garrett, and *B. coli communior* from feces. We also immunized rabbits with the white and red forms of 9 strains of *B. coli mutabile* and tested their sera for agglutinins for homologous and related strains of *B. coli mutabile*, *B. coli communior*, *B. typhosus*, *B. paratyphosus* A and B. The results are summarized in Tables IV and V.

It is obvious that agglutinations on sera of babies do not offer proof of the etiological rôle of this organism. A higher percentage of the sera of sick babies than of well babies agglutinated this organism but our series is too small for conclusions. Fothergill⁸ was only able to offer serological evidence of pathogenicity in 2 cases of his series of babies suffering from diarrhea the stools of whom yielded atypical paratyphoid-like organisms. In view of the age of the infants it must be remembered that any agglutinins may not have been formed in

TABLE IV

RESULTS OF AGGLUTINATION TESTS ON SERA OF 43 PATIENTS WITH *B. COLI MUTABILE* ANTIGEN (RIMMER)

Highest Dilution of Serum Showing Agglutination

Group	Number	Neg.	1:20	1:40	1:80	1:160	1:320
Sick babies	5	3	1	..	1

Mothers .	13	1	..	1	5	6	..
Sick adults	10	2	..	2	3	3	1
Normal adults	2	1	1

response to an infection but may have been passively acquired from the mother.

Rabbits were immunized by introducing the antigen into the marginal ear veins. By giving the rabbits 2 series of 5 injections at 1 day intervals with an intervening rest period of 5 days we were able to produce high titers of agglutinins. We can offer no exact results—it may be stated that some of our strains were highly toxic to rabbits when injected in the fresh state and we used heated cultures for most inoculations.

While rabbits were immunized with 9 cultures and the sera tested with heat killed antigens prepared from all strains, no attempt is made to present the complete results because of the involved charts necessary.

A striking serological relationship was demonstrated among all strains of *B. coli mutabile* isolated from sick babies. The sera of rabbits immunized with any one strain agglutinated all antigens to approximately the same titer. No marked antigenic differences between the white and red organisms were apparent. In most cases the red organisms were agglutinated to higher titers than the white—even by white sera. This happened after every effort had been made to prepare red antigens in a manner

that would eliminate any tendency toward spontaneous clumping because of the granular character of growth.

No close antigenic relationship existed between our *B. coli mutabile* strains and *B. coli communior* isolated from feces during routine examination. Likewise there was no marked cross-agglutination with typhoid or paratyphoid organisms.

Table V presents a summary of some of our serological tests.

SUMMARY

1. *B. coli mutabile* was isolated from the stools of 67 per cent of new-born babies suffering from an unrecognized type of diarrhea.

2. Stable lactose fermenting and unstable non-lactose fermenting (in that lactose fermenting descendants continued to be given off) could be derived from all cultures.

3. Dissociation to the lactose fermenting form occurred under stimulation of contact with lactose. Lactose exerted a specific effect since no other condition of growth produced the same result.

4. Utilization of salicin and raffinose was shown to be similar to that of lactose and depended upon the development of variants capable of fermenting these sugars.

5. Biologically the organisms are closely related to *B. coli communior*, but no close antigenic relationship was demonstrated.

6. All strains of *B. coli mutabile* isolated from sick babies were found to form a homologous group when tested with sera of rabbits immunized with red and white forms.

7. Substantial proof that *B. coli mutabile*

Oh Enema!

*Un petit clystere insinuatif, préparatif
et remollient pour amollir, humecter, et
refraîcher les entrailles de Monsieur.*
—Molière

IT is said that the enema habit was introduced into England from France early in the nineteenth century. I have searched my library of English health books which goes back to 1589 and find the first references, with the exception of one author, in 1807 and in 1828. The exception is Francis Bacon, Lord Verulam (1550-1626), in whose writings I have found three references to the "clyster" which was the English word for enema in his time and is, you will note, practically the same word as used by Molière. But Lord Bacon was unusually erudite and there is no doubt that the enema was more popular at that time in France than in England. Sir John Sinclair (1807) notes that, on page 284 of the

Manual of Health, "there is an amusing story connected with the subject of lavements, regarding the lively and amiable Duchess of Burgundy who was the Rosalind of the court of Louis XIV and who was accustomed to take them previous to her going to the theater."

Unfortunately I have never been able to find that Manual of Health. But the word lavement which is the modern French for enema has had an unfortunate influence on our practice. In the Anglo Saxon tradition a washing demands soap and so to the ancient clyster or glyster soap was added, as it never had been before, and colons suffered in consequence. Doctor Hurst believes this evil practice still to be limited to the British Isles. Alas we know better.—J. Rosslyn Earp, Dr.P.H., *New Mexico Health Officer*, Aug., 1935.

THE SIXTY-FOURTH ANNUAL MEETING

THE 64th Annual Convention of our Association is a thing of the past. The meeting in Milwaukee will go down as one of record. The attendance was next to the largest which we have ever had and the largest by far since the registration fee has been charged.

Of the arrangements made for our comfort and the efficiency with which they were carried out, it is impossible to speak too highly. The Milwaukee Auditorium, although not so new as some others, and perhaps not quite so big, is most admirably fitted for a large meeting, with an abundance of halls in which the acoustics are excellent.

The service was the best that we remember. Each room was supplied with one "monitor" and often two. In every meeting room there were lanterns, an officer to turn the lights on and off and another to operate the projection apparatus, so that it was a matter of a minute at most to go from lantern slides to text and back again. For the first time admission to the halls depended on the official badge and these monitors gave great assistance in protecting the sessions from the idle curious.

The Auditorium is abundantly provided with rest rooms and toilets, and there was also a good restaurant for simple meals, so that one could spend the entire day without returning to the hotel which was headquarters—some two blocks away. All meetings were held in the Auditorium and all breakfasts, luncheon meetings, dinners, and banquets at the Hotel Schroeder.

Our meeting was preceded by The Health Education Institute which has come to be an established feature. The attendance was 128. The general subject taught this year was "Health Education Applicable to Smaller Communities."

For the first meeting day, Monday, the 7th, there was a large attendance, running to 1,600 by noon. Our total attendance was 2,041. The programs, of

which we believed we had a full supply, were exhausted on the second day of the meeting. In spite of the abundant provisions made by the Local Committee, all registrations for all the inspection trips were in excess of the facilities. The banquets, luncheons, and dinners were all over-subscribed. The meeting rooms were full and on some occasions the session had to be adjourned while larger halls were made ready for the audience. All of this was true in spite of the fact that the arrangements were better than we have ever had before.

Among the unusual features was a tea at the Schroeder Hotel given by the Local Committee on Sunday, October 6th, which was tremendously attended. A Tyrolean orchestra was provided, with excellent singers, in costume. Special Tyrolean dances beautifully done and most entertaining were given. The guests sat at tables and feasted. In addition, at 6:00 o'clock in the evening the Local Committee gave a dinner ostensibly for the Governing Council, but all members of the Association who were present were invited. Again we had delightful music and special dancing by local artists.

On Monday evening, the first General Session was held. The welcome was given by Daniel W. Hoan, who has been Mayor of Milwaukee for some 20 years, and who has made of Milwaukee one of the safest and most prosperous cities in the United States. Address of the President of the Association, Dr. E. L. Bishop, followed. A most unusual and delightful feature was the presence of the Honorable Josephine Roche, Assistant Secretary of the Treasury, in charge of public health, who gave an excellent address. The Sedgwick Memorial Medal was awarded to Dr. Haven Emerson of New York, the presentation being made by Dr. William H. Park, a former recipient of the medal. The meeting ended with the usual reception and dance.

On Tuesday night a banquet at which approximately 900 people were seated was provided through the courtesy of the Krim Ko Company of Chicago. A most witty toastmaster, Judge John C. Karel, introduced those sitting at the head table, one by one, speaking to the Mexicans in Spanish, the French-Canadians in French, the Poles in Polish, and to Americans in Americanese. The occasion ended with the singing of well known German songs in which the entire audience joined.

On Wednesday night the annual banquet was attended by more than 600 persons. Dr. Walter H. Brown was inducted into office as President, and gave a scholarly address. A pleasing incident was the presentation by the State and Provincial Health Authorities of North America of an Honorary Life Membership to the retiring President, Dr. Bishop. Dr. C. A. Harper, Health Officer of Wisconsin, the oldest state health officer in this country in years of service, made the presentation in the name of that society.

The exhibits, both commercial and scientific, were unusually large and well prepared. Among the scientific exhibits, citations of merit were awarded to the Marquette University School of Medicine, the University of Wisconsin and State Board of Health of Wisconsin, Laboratory of Hygiene, the Commonwealth Fund of New York, the Wisconsin Anti-Tuberculosis Association, the Milwaukee County Chapter of the American Red Cross, and the American Medical Association of Chicago, Ill. The exhibition halls were at practically all times well filled, and one was forced to the conclusion from the attendance at the meetings in general, the number and size of the commercial exhibits, and the interest shown in them by the public, that conditions throughout the country are better than for several years.

Among the distinguished visitors was Dr. Einar Rietz, Health Officer of Stockholm, Sweden, who addressed a dinner session of the Health Officers. From Mexico we had a single representative—Dr. Angel de la Garza Brito. Our sister republic on the North was better represented than usual. From several provinces we had 17 distinguished men headed by Dr. R. E. Wodehouse, Deputy Minister of Health. From Ottawa came also Dr. Norman Harris, Director of Hygiene of the Federal Department of Health, Mr. Lancaster of the Food and Drugs Department and Mr. Tracy of the Bureau of Vital Statistics. Montreal was represented by its distinguished Health Officer, Dr. Boucher and his Sanitary Engineer, Mr. Cousineau. The Connaught Laboratories sent Dr. Defries, accompanied by Professor Don Fraser. McGill University was represented by Dr. Grant Fleming, Professor of Hygiene.

Dr. Gordon Jackson, the successor of Dr. Hastings, for many years a member and past president of the Association, came from Toronto. The Ontario Department of Health was represented by Dr. John T. Phair. From far Quebec Dr. E. Langevin of the Provincial Department of Health came. We regret that a number of familiar faces were missing.

The Metropolitan Life Insurance Co. sent its representatives, Mr. Burnette and Miss Alice Aherne from Ottawa.

We must express the most sincere appreciation for the coöperation given to us by the local and state authorities as well as by all other agencies. An excellent performance must be recorded on the part of the press and the radio—national, state, and local.

We offer our most sincere thanks to Dr. John P. Koehler, Chairman of the Local Committee, to whose untiring efforts and efficiency the success of the meeting has been largely due. His unfailing courtesy and foresight made the way smooth and pleasant for all of those in attendance. Milwaukee will long be remembered for its bounteous hospitality.

TRIALS OF THE HEALTH OFFICER

A RECENT occurrence in California gives an idea of what health officers may meet with in carrying out their duties. In the spring of 1935, a bakery which sold and distributed bread in San Francisco put out a whole wheat product, on the wrapper of which were the words "Relieves Constipation Nature's Own Way." Newspaper advertisements carried the same phraseology.

The Director of Public Health of San Francisco believed that this was a violation of a section of the Pure Food and Drug Law of the city and county, as well as of a similar section of the Pure Food and Drug Act of the State of California. A conference of those concerned in the baking industry, at which there was also a representative from the State Board of Food and Drug Inspection, was called and held at the Department of Public Health. Free discussion took place. The baking plant involved agreed to remove the phrase "Relieves Constipation Nature's Own Way" from its advertising and also from the bread wrappers. An executive order was issued by the Director of Public Health prohibiting the sale and distribution of bread and other bakery products so labelled as to indicate that the use of such products would relieve constipation and that the said products possessed laxative properties.

Soon after, the bakery in question revived its advertising campaign, con-

fining itself to bill-boards and newspapers. The phrase "Avoid Constipation the Natural Way" was substituted for the older one. The Department of Public Health held that the meaning was practically the same.

The advertising agency employed by the bakery challenged the legality of the executive order issued by the Director of Public Health, and the matter was referred to the City Attorney, with the following result:

The city attorney holds that the Director of Public Health cannot prohibit the distribution of this bread by virtue of an executive order; and any order of the Director of Public Health must be predicated upon the provisions of an ordinance enacted by the legislative branch of the city government, to wit, the Board of Supervisors. The second part of the opinion of the city attorney relates to the validity of the label now used by this Baking Company, namely, the use of the phrase "Avoid Constipation the Natural Way." In the opinion of the city attorney the use of the expression "Avoid Constipation the Natural Way" is of such a generic type as to fall within the category of trade exhortation or invitation rather than positive declaration as would be assigned to statements as "cure" or "relieve" constipation.

The bread in question is a whole-wheat bread containing, besides the natural ingredients, honey and an ingredient—so-called secret formula—claimed to impart to the bread its alleged virtue in relieving constipation. A report from a private laboratory concerning this ingredient is couched in the following language: "A concentrated plant product which has cathartic properties, and when used in specified amount in bread has a mild laxative effect without harmful or unpleasant after effects. Sample as submitted contains no toxic or harmful constituents when used in proper amount."

The Department of Public Health of the city and county of San Francisco is not convinced, and still holds the opinion that such bread is not necessary in the American dietary, and, further, that the advertising used in this sales campaign will have a prejudicial effect upon the consumption of bread.

THE OPEN FORUM

REGINALD M. ATWATER, M.D.

Executive Secretary, American Public Health Association

"TWENTY-FIVE YEARS OF LIFE CONSERVATION"

THIS publication from the Metropolitan Life Insurance Company is unique in its field. It is a record of the organized welfare work of the company on the occasion of the 25th anniversary of the establishment of this Welfare Division but it has much wider significance. It illustrates well the great possibilities of conserving human life inherent in the institution of life insurance. This record also presents striking evidence, as the foreword points out, of the important interrelations which must exist among all groups working to protect health and to extend life. In recognizing the contribution of the public health profession toward these achievements there is an added word of recognition which organized public health owes to the pioneering leadership of the late Dr. Lee K. Frankel and his associates who have so ably furthered the development of many activities both within and without the company itself. As a means of interpreting the life-saving facts of medical science and passing them on to the public in words they can understand, this record is very significant.

In these 25 years—

... the people of America have experienced war, pestilence, flood, drought, unprecedented extremes of heat and cold and a valley of deep depression. Yet, in this quarter century more than eight years—3,000 days—have been added to the average life span of the general population and this "vast gift of days" has gone chiefly to the young.

I know of no better condensed summary of the progress of public health

during this period than that in this publication, which is well illustrated with understandable graphs of tuberculosis, typhoid fever, diphtheria and infant mortality. It would be an excellent text book for educational classes, for it shows what applied science can do in the extension of life. The place of this Association and its committees is well described. It is worthy of note, as the 15th birthday of our Committee on Administrative Practice is being celebrated, that the original grant for the purposes of this committee came from the Metropolitan, which has made grants each year since for the purposes of the Association. Those wishing to secure copies should write Dr. Donald B. Armstrong at One Madison Avenue, New York City.

WHITE ELEPHANTS

NOT a few health agencies have turned the present difficult economic situation to their own great profit by securing gifts of properties suitable for their purposes from persons and estates which regarded these possessions as great burdens. It has been most gratifying to note with what an enthusiastic welcome the idea of a gift has been received by some of the prospective donors who, tired of the mounting tax bills, and eager for some solution, find that a gift to such an agency provides a splendid chance to help public health and get out from under a difficult problem. From the standpoint of the agency it is often possible so to arrange the ownership of the property as to provide for tax-free

use and in this manner to free funds previously used for rent on quarters perhaps much less suitable for the purpose of the organization.

Sometimes it is possible to find a residence of the type popular some years since which is well located and capable of arrangement to accommodate a health center. It is surprising how the use of a few partitions and redecorating can transform one of these buildings into a place suitable both for health department offices and clinic purposes. Not infrequently the whole atmosphere of a department can be raised through such a new provision of space and the health department sometimes profits greatly by separation from certain other governmental agencies which still are known for their partisan political activities.

In other places it has been possible to provide through such gifts of residence property a community center where most of the health and welfare offices may be consolidated. The testimony of some who have tried it indicates that it does a health department staff no harm to see their colleagues in welfare and character-building agencies at frequent intervals. Such a plan serves to emphasize the essential community of interest between officials of the city or county and the executives of health and welfare associations, the visiting nurse group, the Red Cross, the Boy Scouts, and similar agencies. Often the coöperation of service clubs, community chests, etc., can be readily obtained to make it a community unit of large significance.

This type of project has been accomplished in numerous communities from California to New York. It might be achieved in a good many other places if this idea could strike fire in the mind of somebody who would take advantage of this difficult time and perhaps be responsible for opening a new door for health service in his locality.

HEALTH ADMINISTRATION IN NEW YORK STATE

THERE has come to my desk a recently published outline of the administrative procedure in the New York State Department of Health, published in connection with the Extension Course in Public Health given by the department and of which Dr. Don M. Griswold is in charge. Those interested in the description of the routine in this outstanding state department will find each division explained as to its objective and methods. There are illuminating diagrams of the division of responsibilities among the large state staff and their relationships with the 796 local health officers serving 1,222 health districts. Dr. Griswold advises that he is interested in an interchange of information with other departments on this subject. This outline should prove valuable to other administrators and to those teaching public health administration.

IF AND WHEN

SO many questions are in the minds of health officers and others these days about the terms on which grants will be made to states for maternal and child welfare under the Social Security Act that it seems desirable to call attention to an enlightening document on the subject. "Grants to States for Maternal and Child Welfare under the Social Security Act" has been published by the Department of Labor for the Children's Bureau. This publication, which is obtainable from the Superintendent of Documents at 10 cents, describes the provisions of parts 1, 2, and 3 of Title V of the act on Maternal and Child Health Services, Services for Crippled Children, and Child Welfare Services. The anticipated apportionment of funds to the several states is described and the special allowances to each state for ratio of rural population to total rural population will be in-

teresting in view of the special rural provisions of the bill.

RURAL APPRAISAL FORM

DURING the past year there have been more systematic appraisals of rural health services than ever before, due largely to the new Rural Health Conservation Contest sponsored by the United States Chamber of Commerce in coöperation with this Association. Repeatedly it has been evident that the *Rural Appraisal Form* as published in 1932 has been useful and stimulating to health officers in objectifying their own work and for purposes of comparison with other records. Many of those who have used these forms have pointed out what seemed desirable directions for improving the appraisal schedule and careful note has been made of these suggestions.

Now preparations are under way for the revision in 1936 of this schedule and the time is ripe for those who have ideas on this important subject to send them in. I am sure that by this type of coöperation we all can profit through a more adequate appraisal form for years to come. Send in your suggestions. They will be carefully considered by the committee. I can loan you a copy of the *Rural Appraisal Form* if you wish.

PUBLIC HEALTH AND RACE PROGRESS

THE following editorial is reprinted by permission of the Editor of the *New York Times*, from the issue of Friday, September 27, 1935. It is an answer to one type of critic familiar to the health officer:

"PROTECTING THE UNFIT"

The president of Colgate University is worried. "Nothing could threaten the race," he tells us, "as seriously as social legislation. It is begging the unfit to be more unfit and inviting the fit to join the ranks of the unfit." The sins of the philanthropists are equaled only by those of the doctors, who have "done everything they could to keep

the unfit" and to curb "nature's natural checks." He wants us to weed out the feeble-minded, and he fears that even old-age insurance "removes one of the points of pressure which has kept many persons up to the strife and struggle of life."

A curious aroma of nineteenth-century evolutionism floats over these strictures. Perhaps if Dr. Cutten studied the matter a little further he would be less disturbed. What are the crimes that doctors and social legislation have committed? One of their greatest achievements has been a material reduction in the infant mortality rate. In New York City, for example, there was a steady reduction from 113 per 1,000 births in 1910 to 53 per 1,000 in 1933. How has this been achieved? Through increasing precautions to insure a clean, safe milk supply. By increasing knowledge of hygiene, the provision of visiting nurses, medical supervision and advice for expectant and nursing mothers. By increasing knowledge of how to combat specific diseases. There is no evidence whatever that any of these measures have weakened the stock.

What has been done by social legislation in industry? First, there is factory inspection, to insure sanitary conditions, air and light, fireproof buildings. Next there are measures limiting excessive hours of work, night work for many women, child labor. Do these measures increase the number of unfit? Finally, there are the measures, long known to Europe, now just being introduced here, to provide unemployment insurance, old-age insurance and unemployment relief. Of these the first two hardly do more than mitigate somewhat the evils and insecurities that at some time or other affect the majority of us. Only the last can be said to be a measure to "protect the unfit," and then only if it is continued indefinitely. There is no evidence to show that the great majority of the present unemployed are any more "unfit" than the majority of the employed. And if Dr. Cutten is doubtful over old-age pensions—to people over 65—because it "removes one of the points of pressure which has kept many persons up to the strife and struggle of life," he ought surely to be even more doubtful about allowing vigorous young men to inherit enough wealth so that they do not have to work at any time.

"Nature," Dr. Cutten tells us, "provides immunity to certain diseases by eliminating all those who contract the diseases. Now we have a protected race rather than a resistant race." But the creation of protections is almost a definition of civilization

itself. If we were to carry Dr. Cutten's argument to its logical conclusion, we should abandon our present efforts for assuring an uncontaminated water supply, which has done so much to eliminate typhoid and cholera, and give up such fancy services as food inspection, drainage and sewage disposal. As soon as we heard of an epidemic we should, on the contrary, expose everybody to it to make sure that the unfit were eliminated. Perhaps even that would not do much good. Dr. Cutten may be discouraged to learn that

geneticists have calculated that even if all the feeble-minded of this generation could be sterilized it would reduce the feeble-minded of the next generation by only one-tenth to at most a fifth.

EPIGRAM

"There is more true motherhood in giving children toxoid than in embroidering their petticoats these days."
--Elizabeth Cook.

BOOKS AND REPORTS

The Principles and Practice of Medicine—Originally written by the late Sir William Osler, M.D. Revision by Thomas McCrae, M.D. New York: Appleton-Century, 1935. 1196 pp. Price, \$8.50.

Few books have ever enjoyed such popularity as this, the preface to the first edition of which is dated January 1, 1892. It has been copyrighted 18 times. Since the death of Sir William Osler the revisions have been prepared by Dr. Thomas McCrae, and the present 12th edition has a peculiar and sad significance in the death of Dr. McCrae on June 30 of this year, just after the book appeared.

This edition has been completely reset and a new type adopted which is not only considered easier to read, but allows more words to the page. The preface points out changes and additions in practically every part of the book, but especially in the discussion of diagnosis and treatment. Some new sections have been added and others materially altered. A list of these given in the preface makes for easy comparison.

It would require a great amount of boldness to criticise a work which has been so thoroughly reviewed in every part of the English speaking world and has remained a standard for so many years.

We have always felt that proper treatment of contagious diseases, with isolation and scientific disposal of the discharges of the body played a great part in prevention. It goes therefore without saying that those engaged in public health work should have a sound knowledge of disease and the handling of cases. We know of no book which

can be recommended more fully for this purpose than the one before us. The printing and make-up are excellent.

MAZŸCK P. RAVENEL

New and Supplementary Facts and Figures About Tuberculosis—By Jessamine S. Whitney. New York: National Tuberculosis Association, 1935. 46 pp. Price, \$.50.

The present edition is issued so as to make available revised and more recent data, and additional matter.

As the title implies, the booklet is confined mainly to statistics; there is no text, except for introductory comment in the section on tuberculin tests. The 36 tables fall, in the main, into the following classes:

(a) Mortality from tuberculosis, and its variation with age, race, sex, form of disease, time and place (22 tables);

(b) Tuberculous infection: seven tables showing the results of tuberculin tests, in various age groups, by sex, as reported by various observers in the scientific literature;

(c) Miscellaneous data concerning hospital beds, stage of disease on admission to sanatoria, volume of tuberculosis nursing service, and seal sale receipts.

Anyone interested in tuberculosis will want to have a copy of this useful publication constantly at hand. The question might be discussed whether its usefulness might not be enhanced by the addition of graphs for some of the age and time series. For example, the interpretation of Table 5, showing percentage decreases in the tuberculosis rate by age-sex since 1922, would be aided greatly by a graph.

A. W. HEDRICH

Children's Dentistry in Honolulu: Report of Palama Settlement Dental Clinic for School Children, 1934—By *Mervyn I. Conner, D.D.S., Dental Director*. 24 pp.

Dental service at Palama Settlement, Honolulu, is reported for 1934 by Mervyn I. Conner, D.D.S., Dental Director.

Forty-nine per cent of the pupils in the first 5 grades were deemed eligible by the dental hygienists for clinic service. The fees paid by the children amount to 4 or 5 per cent of the cost of the service. The clinic is supported by the "Strong Foundation." The service clinic in coöperation with the public school staff of dental hygienists succeeded in securing dental care for 85 per cent of the pupils attending the first 5 grades. The remaining 15 per cent were not cared for but are accounted for in the report. This is probably as complete a service as can be obtained at reasonable expense and is entirely satisfactory from the public health viewpoint. The clinic cared for 7,444 at an annual cost of \$4.71 per pupil in 1934.

Since 1920, this institution has steadily progressed in service to the community. May it continue.

HARRIS R. C. WILSON

Survey of the Ohio State Department of Health, 1935.

A survey of the Ohio State Department of Health has recently been completed, as part of the Ohio Government Survey, initiated by the Governor, Martin L. Davey.

The report on the Department of Health was prepared by the following committee: Dr. J. A. Doull, Western Reserve University, *chairman*; Howard Whipple Green, Cleveland Health Council, *secretary*; George Gascoigne, consulting engineer, Cleveland; Miss Marion G. Howell, Dean School of Nursing, Western Reserve University,

Cleveland; and Dr. A. Graeme Mitchell, University of Cincinnati. The Committee was assisted by Miss Pearl McIver, U. S. Public Health Service, who surveyed the Nursing Division; A. W. Hedrich, Sc.D., Johns Hopkins University, who surveyed the Vital Statistics Division; and Mr. A. A. Keiser, of the National Cash Register Co.

A historical sketch outlines the creation of the Board of Health in 1886, and the gradual development of administrative divisions; the reorganization in 1917 into a State Department of Health, headed by a Public Health Council and a Health Commissioner selected by them to serve a five-year term; and another re-organization in 1921, whereby the Health Commissioner was replaced by a Director of Health, appointed by, and serving at the pleasure of, the Governor. In the same re-organization, vital statistics functions were transferred from the office of the Secretary of State to the Department of Health. The Commissionership has changed hands frequently in recent decades, but the Assistant Commissioner has been in office nearly forty years.

There are, at present, six Divisions of the Department: Administration, Communicable Disease (including Bureaus of Venereal Disease, Tuberculosis, and Blindness Prevention), Vital Statistics, Laboratories, Hygiene (including Bureaus of Occupational Disease, Child Hygiene, Maternity Hospitals, and Dental Hygiene), and Sanitary Engineering.

As has occurred in other states, the Department suffered a severe reduction in appropriations, illustrated by the following comparison of expenditures in 1930, the peak year, and in 1934:

Year	Total Subsidies to			
	Expenditures	Local Depts.	Personnel Services	Maintenance
1930	\$630,560	\$251,098	\$276,561	\$102,901
1934	378,048	150,000	178,486	49,561

It is seen that the total expenditures declined by 40 per cent, subsidies to local health departments the same proportion, personnel services 35 per cent, and maintenance, 52 per cent. Personnel was cut from 137 persons to 92: the nursing staff was cut from 14 persons to 3; and there were dropped 8 stenographers, 5 chemists, and 4 physicians, along with other personnel.

The Committee found that, on the whole, the Department was efficiently and economically conducted. For example, the laboratory cost of performing the conventional double test for syphilis was approximately 21 cents; at commercial rates the cost would have exceeded the entire budget of the Health Department. The central office expense for registering births and deaths (not including county fees to local registrars) was about 15 cents per certificate, compared with a cost of registering animals in appropriate registries of \$1 to \$3 for hogs and sheep, to as high as \$4 to \$20 for horses. Accordingly, whereas further cuts in budget aggregating five millions were recommended by committees for other departments of the government, the Committee on Public Health felt obliged to recommend increases for the Department of Health proper, as follows: salaries and wages, \$16,260; maintenance, \$1,851. It was, however, recommended that subsidies to local departments be reduced from \$150,000 to \$125,000.

Perhaps the most important recommendation of the Committee was that, subject to approval of the Public Health Council, the Director of Health be given a free hand in the allocation of local subsidies, according to the needs of local communities. This policy would enable him to promote the consolidation of health districts and in other ways stimulate efficiency and economy. This, and other recommendations are in harmony with those

made by Dr. Joseph W. Mountin in a Report of the Governor's Commission on County Government, submitted in December, 1934.

Among other recommendations are:

That the term of the Director of Health be made indeterminate; that he shall be subject to removal only for incompetency, misbehavior, or age limitation; and that appointment and removal by the Governor be subject to approval of the Public Health Council; retention of the present Director is recommended;

That the "exemption privilege," permitting an incoming Director arbitrarily to remove three employees from the classified list, be abolished;

That a second Assistant Director of Health be appointed; the first Assistant would then have charge of administrative activities, such as personnel, legislative, purchasing, and publicity; the second Assistant would have charge of local health organization and preventive medicine activities. Divisions reporting directly to the Commissioner would be Vital Statistics, Laboratories, and Sanitary Engineering;

That additional personnel be provided, including an epidemiologist at \$3,600, a dental health officer at \$3,600, a nursing supervisor at \$2,500 to \$3,000, and three public health nurses, aggregating \$5,400;

That a new state laboratory be constructed, and that the Division undertake histo-pathological and toxicological examinations; and

That the food and dairy activities of the Department of Agriculture and inspection of hotels and restaurants by the Fire Marshall be transferred to the Health Département.

Recommendations were made to individual Divisions concerning procedures, for example, the use of labor saving machinery, elimination of duplications, speeding up of certain operations, and the like. A. W. HEDRICH

A New Angle on Health (Nature's Provision for the Health and Happiness of Mankind) — *By Surgeon Captain D. H. C. Given, M.D. London: John Bale, Sons & Danielsson, Ltd., 1935. 160 pp. Price 7s. 6d.*

This book is a sincerely written essay, containing much that is of interest. The author attributes much evil to modern industrialism and the consideration of "self before service." He holds that "Nature is merely the kingdom of God upon earth," and that "Nature's simple recipe for health and happiness inevitably brings one back to the Sermon on the Mount." He concludes by expressing his conviction that "the precepts of Christianity are the only basis of a healthy and happy life."

The book has a number of interesting charts, tables, and illustrations. The printing and make-up are excellent.

We believe that it is better suited as a religious tract than as an essay on hygiene. MAZÛCK P. RAVENEL

Making Our Minds Behave—By William S. Walsh, M.D. New York: Dutton, 1935. 277 pp. Price, \$2.50.

Having been favorably "conditioned" by the sympathetic, approving, and even enthusiastic reviews of this author's books he has seen in the newspapers in the past, this reviewer picked up the present work (the first he has read) with confidence and expectation that here he would find a satisfactory exposition and interpretation of mental hygiene principles and their practical application to everyday life, but he was soon disappointed. It starts off promisingly with an instructive discussion of the relations of emotion to mind, of mental mechanisms like rationalization, of the inferiority complex, of ego and sex drives and one or two other psychobiological

fundamentals, but after the first two or three chapters this mental hygiene content peters out and the book trails off into the popularized, inspirational treatment of "psychological principles" with which we are all familiar.

It can hardly be said to be, as the publishers call it, "a study of psychology and psychoanalysis." Except for this limited presentation of some of the concepts of the new psychologies, the contemporary setting of many of the illustrations and object lessons, and the use of current idiom, the book might have been written twenty years ago.

One wonders what the secret of success of this author is, unless it be his marked ability to talk to his readers in easy, American vernacular, and to supply them with a type of psychological material for which there is apparently still great demand, for he knows what they want and what to give them and how. He writes clearly, simply and interestingly, and tells them much that is sound, sane and sensible, though also much that is trite and even banal.

It is a little disappointing that a physician, who is also a serious student of human behavior and the social sciences, with a gift for popularization that could be turned to good account in the manipulation of sterner stuff, should devote the major part of a work on the science and art of mental hygiene to such shop-worn topics as the art of concentration, self-expression, personal popularity, second-hand thinking, "mental engineering," and "making good on the job." Dr. Walsh might have left to the vocational psychologist and the efficiency experts, for example, the business of advising the young graduate from high school or college how to apply for a job.

There is great need for mental hygiene literature of the self-help type for the laymen. There is already a

large and growing literature for the parent and teacher with reference to the training of the young, but little as yet of a sound and practical nature for the adult himself. It is a paradox that the more successful of our popular books on psychology should be so thin and unsubstantial, and the solid and more valuable material of mental hygiene, educationally speaking, so poorly prepared for popular consumption, when it is available at all.

PAUL O. KOMORA

Child Nutrition on a Low-Priced Diet—By *Mary Swartz Rose and Gertrude M. Borgeson*. New York: Bureau of Publications, Teachers College, Columbia University, 1935. 109 pp. Price, Paper, \$1.00; Cloth, \$1.50.

In this monograph of the Child Development Series the authors have described fully, and clearly, the results of an intensive study of certain phases of nutrition in a group of 60 preschool children maintained on a uniform low priced diet for 21 months, and 19 of the children subsequently kept on the same diet for 10 months longer. The study was carried out as a coöperative research project of the Child Development Institute, various departments of the College and University and of a social welfare organization.

The children were under Day Nursery supervision and were divided for purposes of study, into two groups matched as nearly as possible as to age and sex. The diet of one group was supplemented by an egg a day for each child. Careful supervision by a nutritionist and physician was maintained throughout.

The principal conclusions are as follows:

1. The uniformity of the health progress of the two groups.
2. The efficiency of a very inexpensive diet for young children if chosen with knowledge

of nutritive values, and administered with due regard for ease of digestion and regularity of food consumption.

3. Milk furnished on the average 36 per cent of the total calories.

4. The total cost of the diet without eggs averaged about 1.6 cents per 100 calories.

5. The differences in growth of egg and no-egg groups were not significant with respect to either height or weight.

6. No differences in growth, general health status, or hemoglobin and red cell values of the blood could be attributed to the added orange juice.

7. No special benefit from the substitution of liver for egg could be detected.

This work merits careful consideration and should be read by all those interested in child development.

One would like to see similar studies carried on for preschool children in other parts of the country, as reports have been coming in that this age group has suffered more severely during the depression than any other.

RICHARD A. BOLT

Health Dentistry for the Community by the Committee on Community Dental Service of the New York Tuberculosis and Health Association — Edited by *Michael M. Davis*. Chicago: University of Chicago Press, 1935. 85 pp. Price, \$1.00.

This volume brings together much valuable information as to what is being done for both children and adults in the matter of dental service for the financially less fortunate. The various problems are discussed freely and frankly. It will be found most readable and enlightening if not entirely pleasing to the conservative mind. Some suggestions are made for the solution of dental problems for all the people.

This volume will be of value to any committee or group planning for community dental service.

HARRIS R. C. WILSON

A Square Deal for the Narcotic Addict—By *William H. Ladue, M.D.* Published by the author. *Plattsburgh, N. Y.: The Tuttle Printing Office, 1935.* 131 pp. Price \$1.00.

This book is chiefly a discussion of narcotic addiction, on which a large amount of good material is given. The object of the author is to compare drug addiction and the hysteria which it has engendered with alcoholism and our complacent attitude toward it. In one chapter called "A Double Standard," he discusses the marked discrepancy between the social significance of alcoholism and drug addiction, and holds that the public conscience acts as though aroused to the higher degree by the lesser irritant. The author holds that drug addiction is not a menace; that there is not an "institution, a vital component of our life as a nation, that is tottering because of narcotics." There is no association comparable to the W.C.T.U. or the Anti-Saloon League to educate the public and fight the use of narcotics. There is no church standing at bay.

Narcotic addiction has been decreasing since about 1900, and this warrants a further trial of educational processes against it. Our attitude toward addiction is wrong, and the compulsory commitment of addicts is one of the most flagrant examples of the relative disregard of personal rights.

The writer disclaims any intention to advocate total relaxation of narcotic control or cessation of commitment, confinement, or punishment of selected addicts who have become a social problem. He holds strongly, however, to the idea that compared with the great alcoholic problem, narcotic addiction has nothing like the importance which has been given to it in the federal laws as well as those of the various states.

The book ends with an appendix

which gives a Digest of Essential Features Required in a State Narcotic Defense Law, proposed by the International Narcotic Education Association. The author makes out a strong case, and his book is well worth reading.

MAZÛCK P. RAVENEL

Common Sense for Mothers—By *Mrs. John S. Reilly.* *New York: Funk & Wagnalls, 1935.* 372 pp. Price, \$2.00.

The author, a mother of seven children, has tried in this book to give to other mothers the results of personal experiences and observations in the rearing of her family. Her counsel is wise and seasoned with a fine sense of humor. The material is well presented.

The author brings out that childbirth is a natural, normal function of woman; although attended by dangers which may be modified by early physical examination and supervision of a capable physician.

Mrs. Reilly places upon the mother a big responsibility for the care and character formation of her children. She feels that in order to do this job successfully, the mother must have good judgment and common sense. She says that housekeeping and the feeding of children has become almost a science; but the training of children is a much neglected field. Mothers have been expected to do this training without preparation. Wise parenthood requires more than good will and traditional ideas.

Adolescence is discussed as the age of transition. Some of the difficulties which confront parents at this time are mentioned.

The material organized in Mrs. Reilly's book is not new; but her method of presentation is somewhat different from other books in the same field, because she has lived in close association with her own family.

ELLEN D. NICELY

The Single Woman: A Medical Study in Sex Education—*By Robert Latou Dickinson and Lura Beam. Baltimore: Williams and Wilkins, 1934. 469 pp. Price, \$5.00.*

This book is one of the series in *Medical Aspects of Human Fertility* issued by the National Committee on Maternal Health and follows the authors' "A Thousand Marriages," published in 1932. The material for it is taken from the same sources, *i.e.*, patients seen in private practice by Dr. Dickinson during the forty years from 1890 to 1930. The point of view is not the narrow one of the specialist, whom the sceptic may accuse of finding what he is looking for, but that of "the family doctor plus the anatomist plus the specialist in the diseases of women." For this reason the book is a social as well as a medical document, and raises more questions than it answers. The single woman has sexual problems, but so does the married woman, and often they are not so different in their actual essence. Frustrated in its normal biological functioning, sexual energy seeks other channels of expression. What direction it takes, whether it remains at the level of physical expression or seeks other outlets, in "work, the arts, religion, family or other people," it is the entire personality of the woman that is involved, and not her sexual nature in the narrow sense. Sexual behavior is thus more of a psychological and social phenomenon than a strictly biological one, and can best be studied in relation to the social and economic currents of a particular epoch. It becomes, too, of paramount concern to education; "sexual illiteracy is costly."

No one in this country is better qualified to speak on such a subject than Dr. Dickinson. The material of the case histories has been skillfully handled, the conclusions are sane and

logical, and the book as a whole is an invaluable contribution to the literature of sex. WINIFRED RICHMOND

Nutrition Work with Children—*By Lydia J. Roberts (rev. ed.). Chicago: University of Chicago Press, 1935. 639 pp. Price, \$4.00.*

Those who have had Miss Roberts' 1st edition of *Nutrition Work with Children* on their shelves as a standard reference for 9 years will welcome this completely revised and considerably enlarged new edition. The present volume reveals an omnivorous appetite for keeping abreast of modern developments in nutrition and a digestive facility in reducing them to 639 pages. The results of modern nutritional research are presented clearly in a manner easily understood even by the uninitiated.

Each chapter is followed by a helpful list of references to original material. The clarity with which the author discusses the difficulties in assessing nutrition is refreshing. The chapters on the causes of malnutrition and the physical and mental effects of undernutrition are written especially well.

However, Miss Roberts has more than an academic interest in malnutrition. More than half of the book is given over to prevention and treatment. The various agencies which may be enlisted are described. The responsibility of the school for the health of its children is stressed, and a practical health program is outlined. The need for nutrition work in the preschool period is recognized.

"There can be no doubt," says Miss Roberts, "that an effective program of school and community betterment must begin back in the preschool period."

The format of the book is excellent, and the well chosen illustrations add considerably to its value.

RICHARD A. BOLT

Biology for Everyman—By Sir J. Arthur Thomson. New York: Dutton, 1935. 2 vols. 1,600 pp. Price, \$5.00.

The last fifteen years have seen quite a number of good, bad, and hack volumes on humanized knowledge. At times it was sufficient for a scribe with a flair for popular writing to read a number of books on a subject in order to produce a so-called outline. Of course, many of the outlines have not only imparted a great deal of accurate information, but have stimulated large masses to take a more intelligent interest in scientific, literary, and religious subjects. Thus, we had such works as the forerunner of all outlines, that of H. G. Wells on history, which must have had a tremendous influence on the entire field of adult education. Of this "Outline of History" the late Arnold Bennett was wont to say that the very conception on the part of the author was highly daring and the actual execution of the design was of course even greater.

The present work may not be exactly an outline, but whatever its name, it was something very much worth doing and few were better qualified for the task than the author of these two volumes. Sir J. Arthur Thomson, besides being a truly great biologist, brought to his task thirty years' experience, both as a teacher and writer, of natural history. Moreover, he always wrote so well that it is a real enjoyment to read what he had to say.

In "Biology for Everyman" the author gives us in 1,600 pages a vivid picture of living things, from amoeba to man; the plant world, heredity, sex and evolution are described and oriented with the rest. He does it with real charm and without the technicalities of the formal text books. The main sections of the work are divided into systematic sub-sections for the benefit of students, so that it may serve

as a reference or enlightened text book. There are also a good many subject references and cross references, 500 fine illustrations, and a valuable index of more than 80 pages. The job of seeing the manuscript through the press was done by Dr. E. J. Holmyard, scientific editor of "Everyman's Encyclopedia." Altogether, a fascinating work which will be read with interest, profit, and pleasure, especially by the lay reader. SAVEL ZIMAND

Modern Motherhood—By Claude Edwin Heaton, M.D., F.A.C.S. New York: Farrar and Rinehart, 1935. 271 pp. Price, \$2.00.

Dr. Heaton has given us a comprehensive book for mothers and prospective mothers presented in a direct, clear-cut style. It is thoroughly up-to-date in answering frankly every question a modern, intelligent woman is liable to ask. Even "The Expectant Father" is recognized as an important adjunct to modern motherhood. A unique feature of the book is the last section devoted to "Obtaining Adequate Maternity Care." In this is discussed the choosing of a doctor and a hospital, and the crucial question of the cost of maternity care. There is a very instructive chapter on the evolution of obstetrical care and a concluding chapter on "American Obstetrics" in which community responsibility is stressed. "Plainly a large majority of American parents," says Dr. Heaton, "belong to classes in need of a new deal in obstetrics."

"To recapitulate the main thesis of this book: the problem of maternal welfare in the United States is primarily a social and an economic one. Expectant parents who are able to avail themselves of the advantages of modern obstetrics may contemplate having a baby with serenity and confidence." A helpful bibliography and glossary are appended. RICHARD A. BOLT

Annual Report of Division of Sanitary Engineering—Georgia Department of Public Health, 1934—*Malaria Control*, pp. 18-25, inclusive.

A narrative report with tabulation of work accomplished on drainage, and employment figures, by counties.

The report of an organization aggressively engaged in the promotion, planning and supervision of work relief labor on drainage operations, rather than in conventional health department engineering functions of approving plans and specifications. The first section deals with a narrative of work operation and description of the administrative organization. It concedes that much of the work involved conflicts with professional malaria control principles, due to extreme limitations and restrictions on public health personnel in proportion to the magnitude of the program, and to characteristic defects and restrictions of CWA and ERA program conditions primarily governed by the furnishing of minimum aid to relief cases. In spite of deficiencies, the program is endorsed and praised as having provided great benefit to numerous individual areas.

Detailed description of the duties and functions of field personnel on malaria drainage is given. Detailed description of program and project difficulties involved in the operation of work relief labor is given. Labor forces employed were almost exclusively provided by relief agencies, although this state has a prior history of malaria drainage by convicts. Work was accomplished in 110 counties, 2,500 ponds were drained, and 6,000,000 man hours of employment were devoted to the program.

The second section deals with malaria prevalence and epidemiological factors. This discussion recognizes rainfall as the principal determinant of malaria prevalence. The "Number of deaths

per inch of rainfall" is computed for comparative purposes in the study of other epidemiological factors, and in evaluating state-wide effectiveness of control. Little consideration is given to total malaria deaths in the state, which it is demonstrated will fluctuate very widely in crude relation to the rainfall, irrespective of all other factors.

A normal expectancy of 8.62 deaths from malaria per inch of rainfall is established by records over a 15 year period. Death rates in excess of this normal expectancy furnish indications of variation in disease virulency, type of disease, changes in the human host, and in the failure of control measures. Rates below the normal occurrence are counter indicative.

The effectiveness of drainage in influencing the state-wide problem as well as restricted local conditions is demonstrated by a declining trend curve, and also by rate curve characteristics for 1934 which show a below normal occurrence in spite of an expected 7 year cyclic increase and by nation-wide statistics of the U. S. Public Health Service.

Secondary curves published show a lag in the up-turn of malaria deaths with increasing rainfall after the end of drought periods (see 1926 and 1932). This is attributed to the accumulated deficiency of pond storage waters, requiring extensive replenishing before marked expansion in anopheles breeding occurs, and to the reduction of carriers. Sustained increase in precipitation resulted in the accelerated increases of malaria deaths occurring immediately after the period of lag.

The relative value of malaria morbidity and mortality reporting is discussed.

Malaria control by mass drug treatment, and thick blood smear surveys are under way in the state, but are not discussed in the engineering report.

JOHN M. HENDERSON

Methods and Materials of Health Education—By *Jesse Feiring Williams, M.D., and Fannie B. Shaw, M.A.* New York: Nelson, 1935. 331 pp. Price, \$1.65.

This book runs the gamut of school health education, discussing such erudite subjects as environmental sanitation, or "healthful school living," health service, and health instruction. In addition, there are chapters on the nature of the child, the construction of the curriculum, tests and measurements in health education, materials for teaching health, and the rôle of various organizations in the now highly developed art and science of health education. As a fitting climax, the health of the teacher receives ardent attention.

Although somewhat pedantic in tone, this well printed book is a valuable contribution to the literature on an important branch of public health. It should prove of practical value to all persons engaged in school health education and deserves wide use for that significant purpose. JAMES A. TOBEY

Bacteriology for Nurses—By *M. A. Smeeton, B.Sc., M.A. (4th ed.)* New York: Macmillan, 1935. 352 pp. Price, \$2.50.

This is the fourth edition of a concise and comprehensive text. In this revision of the book current nomenclature has been introduced; and new subject matter incorporated which is in accord with the results of recent research.

The classification of Prevalent Communicable Diseases, added to Chapter X, furnished a useful summary of information as to the infective agent, source of infection, and period of infectivity. However, the methods of control—as listed in this classification are too brief and generalized to provide much information for the student.

One of the weakest features of the

book is the lack of a bibliography or list of reference readings.

The illustrations are greatly improved, clearly labeled, and well chosen.

Appendix I, dealing with the classification of bacteria is an especially good feature of the book and serves to make more complete a very acceptable text in bacteriology for nurses.

MARY C. EDGAR

Introduction to Psychology. With Special Applications to Nursing and Nursing Interrelationships, 1910-1913—By *Edward S. Robinson and Virginia Kirk.* New York: Macmillan, 1935. 368 pp. Price, \$2.50.

This is no ordinary book on psychology. It contains special applications to nursing and nursing problems.

Praise be, too, it doesn't plunge one immediately, like some of the older texts on the subject, into the intricate anatomy of the nervous system. It is practical and actually interesting.

In the chapter on memory we begin to understand these wordy individuals who dwell on all the inconsequential details when telling a story. The trouble with them is that they do not distinguish between what is significant and what is not, and lose the point of the story; as the author states "they get just as excited over a broken chair as they would over a broken leg."

The material is beautifully arranged, with good paragraph headings and plenty of illustrations. Each chapter is summarized and ends up with a set of problems that are real nut crackers—also with good references for further study.

Nurses are feeling more and more the need to study mental hygiene. A text like this is an essential preliminary to that study. And with the growing emphasis on more university education for nurses—here is a book of real college caliber for them.

EVA F. MACDOUGALL

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

About Alcohol and Tobacco—Why do people smoke and drink? What probable harm do these poisons do? These questions are not answered, but the attempt to do so reaches the usual standard of the unusual magazine which studied the question.

ANON. Alcohol and Tobacco. *Fortune*, 12, 3:67 (Sept.), 1935.

Scarlet Fever among Nurses—In a large group of nurses, the attack rate among those persons susceptible to scarlet fever was 12.8 per cent, whereas among the Dick negative and the immunized groups the attack rate was 0.7 per cent.

ANDERSON, G. W., and REINHARDT, W. I. Scarlet Fever Immunization of Nurses. *J. Infect. Dis.* 57, 2:136 (Sept.-Oct.), 1935.

A Britton Looks at Food Standardization—Calling for a committee to set up standards for certain food products, the author warns against the possibility of raising the price of the standardized foods above the pocketbooks of the poor. He would rather see the poor have plenty of wholesome but so-called second-class foods than too little first-class articles which, while excellent esthetically, would not be nutritionally superior.

BROWN, R. K. Standardization of Food. *J. State Med.* 43, 9:513 (Sept.), 1935.

Heart Disease Causes—Rheumatism was the commonest cause of heart disease, exclusive of the arteriosclerotic-hypertensive types, and syphilis next among the heart disease deaths under review.

HEDLEY, O. F. A Study of 450 Fatal Cases of Heart Disease Occurring in Washington (D. C.) Hospitals during 1932 with Special Reference to Etiology, Race and Sex. *Pub. Health Rep.* 50, 34:1127 (Aug. 23), 1935.

Convalescent Serum against Scarlet Fever—Immune scarlet fever serum will prevent infection in contacts in 95 per cent of the cases; where protection is not complete the disease is modified; it will abort the disease if given early; even if late, it seemed beneficial; no ill effects were experienced.

HOYNE, A. L., *et al.* Convalescent Scarlet Fever Serum. *J.A.M.A.* 105, 10:783 (Sept. 7), 1935.

For the Prevention of Measles—Convalescent serum is still the best prophylactic agent against measles, in the author's opinion. Adult blood is effective, as is placental globulin, though the reaction to the latter may be severe.

KARELITZ, S. Measles Prophylaxis. *New York State J. Med.* 35, 17:876 (Sept. 1), 1935.

Plague in the West—Plague, concludes this article, is a permanent problem on the Pacific Coast and probably will appear in other states. Especially to be feared is the pneumonic form which may be related to the disease in squirrels, ground hogs, and related species.

KELLOGG, W. H. Rodent Plague of California. *J.A.M.A.* 105, 11:856 (Sept. 14), 1935.

Preventing Pertussis—Convalescent serum was found of prophylactic value in whooping cough but of doubtful benefit in treatment. A useful skin test is proposed.

PATERSON, D., *et al.* Control of Whooping Cough with Serum and Vaccine. *Lancet*, 2, 7:361 (Aug. 17), 1935.

Nursing and V. D. Control—Stressing the importance of case find-

ing and follow-up in the control of gonorrhea and syphilis, the author develops the great possibilities of public health nursing contributions to the cause.

NELSON, N. A. *The Prevention and Control of Gonorrhea and Syphilis*. Pub. Health Nurs. 27, 9:463 (Sept.), 1935.

Industrial Hygiene High Spots—Typically British is this philosophical discussion of the health of industrial workers. Most American papers would be more readable were they written with the broader vision of our overseas cousins.

OLIVER, T. *Side Lights upon the Health of Workers and Their Occupations*. J. State Med. 43, 9:497 (Sept.), 1935.

Psychology and the Nursling—That you can lead a baby to milk but you can't make him drink seems to be one of the arresting ideas in this stimulating paper on infant nutrition, which ought to be taken to heart by all who have to do with babies.

POWERS, G. F. *Infant Feeding*. J.A.M.A. 105, 10:754 (Sept. 7), 1935.

In the Baby's Bottle—Buffered lactic acid milk is good for new-born infants. They should experience less initial loss of weight and do better afterward. It is good for premature and debilitated infants, too.

SMYTH, F. S., and HURWITZ, S. *Buffered Lactic Acid Evaporated Milk in Infant Feeding*. J.A.M.A. 105, 10:789 (Sept. 7), 1935.

More about Dr. Topley's Famous Mice—Under experimental conditions, the long continued daily addition of susceptible mice to an infected herd finally reaches a state of epidemic equilibrium in which deaths are constant. Periodicities in natural epidemics must be due to variations in factors kept constant in the experimental environment. Adding immunized entrants lowered the death rate to mouse typhoid, but did not wipe out the epidemic. Conclusions regarding relationships in the diseases of mice and men are stimulating.

TOPLEY, W. W. C. *Some Aspects of Herd Immunity*. J. Roy. San. Inst. 41, 3:123 (Sept.), 1935.

ASSOCIATION NEWS

OFFICERS, 1935-1936

President, Walter H. Brown, M.D., Palo Alto, Calif.

President-elect, Thomas Parran, Jr., M.D., Albany, N. Y.

First Vice-President, Robert E. Wodehouse, M.D., Ottawa, Ont., Can.

Second Vice-President, Prof. Samuel C. Prescott, Cambridge, Mass.

Third Vice-President, Angel de la Garza Brito, M.D., Mexico City, Mex.

Treasurer, Louis I. Dublin, Ph.D., New York, N. Y.

Executive Secretary, Reginald M. Atwater, M.D., New York, N. Y.

Chairman of Executive Board, John A. Ferrell, M.D., New York, N. Y.

THE NEXT ANNUAL MEETING WILL BE HELD IN NEW ORLEANS, LA.

WALTER H. BROWN, M.D., PRESIDENT

THOMAS PARRAN, JR., M.D., PRESIDENT-ELECT

AT the Sixty-fourth Annual Meeting in Milwaukee, Wis., Eugene L. Bishop, M.D., retired from the office of President of the American Public Health Association and Walter H.

Brown, M.D., of Stanford University, Palo Alto, Calif., became President to serve for the year 1935-1936. Dr. Brown is well known in Association circles, having served in numerous

Walter H. Brown, M.D.

Thomas Parran, Jr., M.D.

capacities—most recently as President of the Western Branch of the A.P.H.A. Dr. Brown is a graduate of Jefferson Medical College, Philadelphia, and practised medicine in Pennsylvania for several years prior to his graduation from the Harvard-M.I.T. School for Health Officers in 1914. He served as Epidemiologist of the Massachusetts State Department of Public Health; as Health Officer of Bridgeport, Conn.; as Associate Director of Health Service of the American Red Cross; and was assigned to the Commission for Prevention of Tuberculosis in France by the Rockefeller Foundation at the close of the war. Later Dr. Brown became the Director of the Child Health Demonstration in Mansfield, Ohio, and subsequently was Director of the Child Health Demonstration in Marion County, Ore. Since 1927, Dr. Brown has been Professor of Hygiene at Leland Stanford University. He has been a member of the A.P.H.A. since 1915 and a Fellow since 1922.

The new President-Elect is Thomas Parran, Jr., M.D., Commissioner of Health of New York State. Dr. Parran, who is a graduate in medicine

of Georgetown University, has been identified with the U. S. Public Health Service since 1917. Among various assignments he has served as Chief Medical Officer of Muscle Shoals, Ala.; Executive Officer of the Medical Division of the War Risk Insurance Bureau; Director of the Tri-State Sanitary District; Director of Rural Sanitation in the Missouri State Department of Health, and in a similar capacity in Illinois. In 1925, Dr. Parran was made Chief of the Division of Venereal Diseases in the Public Health Service with the rank of Assistant Surgeon General, where he served until his appointment in 1930 by Franklin D. Roosevelt, then Governor, as Commissioner of Health in New York State. Dr. Parran is a member of the Committee on Research in Syphilis. He has served as Treasurer of the Association for 2 years, and since 1933 has been Chairman of the Executive Board, which brings to him a valuable familiarity with the current affairs of the Association.

Dr. Parran has been a member of the A.P.H.A. since 1919, and a Fellow since 1923.

THE SEDGWICK MEMORIAL MEDAL

AT the Milwaukee meeting the Sedgwick Memorial Medal for distinguished service in public health was awarded to Haven Emerson, M.D., of the College of Physicians and Surgeons, Columbia University, New York.

Dr. Emerson is well known to the Association, having served as President 1933-1934. He is a graduate of the College of Physicians and Surgeons in New York, class of 1899. He was Commissioner of Health of New York City 1915-1917 and has had teaching connections with Cornell University and the New York School of Social

Work besides his present connection as Professor of Public Health Administration at Columbia, where he has been since 1922. Dr. Emerson was a Colonel in the U. S. Army during the World War and is now a member of the National Advisory Health Council of the U. S. Public Health Service.

Among other awards which Dr. Emerson has received have been the Distinguished Service Medal, the *Medaille des Epidemies*, and the *Chevalier Legion d'Honneur* (France). The Sedgwick Memorial Medal was presented by William H. Park, M.D., of New York, himself a recipient of the

medal in 1932. Dr. Park paid a fitting tribute to the memory of Professor Sedgwick, and spoke of the eminent qualifications of Dr. Emerson for this honor.

Replying to the presentation, Dr. Emerson said:

"In accepting this token from your hands, Dr. Park, I recognize the occasion as one when friends and disciples delight to do honor to the memory of a great teacher.

"Someone, each year, is chosen to serve as a sort of proxy, and I appreciate the temporary privilege of playing a part in reenacting the annual tribute of admiration for the character and life work of William Thompson Sedgwick.

"He most happily personified that rare but indispensable individual, whom Matthew Arnold so handsomely described:

The great men of culture are those who have had a passion for diffusing, for making prevail, for carrying from one end of society to the other the best knowledge, the best ideas of their time; who have labored to divest knowledge of all that was harsh,

uncouth, difficult, abstract, professional, exclusive; to humanize it, to make it outside the clique of the cultivated and the learned, yet still remaining the best knowledge and thought of the time.

"Professor Sedgwick was such a great man of culture.

"This precious golden disk I shall keep before me, in the hope that by good fortune and hard work I may do something for the students of today, which will make them as useful in our society as are everywhere the students of Sedgwick."

Previous recipients of the Sedgwick Memorial Medal were:

- 1929 Charles V. Chapin, M.D.
- 1930 Theobald Smith, M.D.
- 1931 George W. McCoy, M.D.
- 1932 William H. Park, M.D.
- 1933 Milton J. Rosenau, M.D.
- 1934 Prof. Edwin O. Jordan

The Chairman of the Committee on Award of the Medal for 1935 was Surgeon-General Hugh S. Cumming, of Washington. Beginning in 1936, the Committee of Award will consist of the five most recent recipients of the Medal.

LEGITIMACY RECORDS ON BIRTH CERTIFICATES

AT the Milwaukee Annual Meeting the Section on Vital Statistics passed unanimously a resolution looking toward the removal from all birth records of statements of legitimacy. It was stated that about 50,000 babies are acknowledged as born out of wedlock each year in the United States and that the true number was closer to 100,000. These birth records are recognized as being no better than casual statements of purported fact, and are of course subject to the usual tests of evidence. The stigma involved for the child is so great that the social usefulness of these reports is open to serious question.

"In pursuance of the recommendation of the Committee, the Vital Sta-

tistics section unanimously resolved that the committee should take steps leading toward the elimination from official birth records of all references to legitimacy of the child.

"It was the further sense of the section that the future work of the committee should be guided by the concept that no child in America should be denied the equality and the complete freedom to pursue happiness, which, in the words of the Declaration of Independence, are the inalienable rights of all men."

The Chairman of this committee, J. V. DePorte, M.D., of the New York State Department of Health, said:

"At present a child born out of wedlock is stigmatized for life. In

recent years the injustice of penalizing a child whose parents were not married has come to be recognized; hence the increasing acceptance of the viewpoint that there may be illegitimate parents, but there can be no illegitimate children."

Thomas Parran, Jr., M.D., New York State Health Commissioner, endorsed this action of the section and stated that plans have been made to make effective this recommendation

through legislative action in New York State sponsored by Governor Lehman.

This Section action was considered by the Governing Council of the American Public Health Association and approved for publication as representing the attitude of the Association. It has received wide newspaper attention and the section officers have suggested that the time may now be ripe in many states for definitive action.

CHANGES IN THE BY-LAWS MADE AT THE ANNUAL MEETING

ON the recommendation of the Association Committee on Constitution and By-Laws, composed of Henry F. Vaughan, Dr.P.H., *Chairman*; Haven Emerson, M.D., and John A. Ferrell, M.D., the Governing Council at Milwaukee adopted two changes in the By-Laws which will be of interest to the membership.

Having in mind the desire to broaden the group of persons who carry important Association responsibilities, it was decided that hereafter those Fellows who were elected to and who accepted membership upon the Executive Board should be ineligible for membership on any of the Standing Committees of the Association. This provision will serve an additional purpose of making the Executive Board a more judicial agency in passing upon the budgetary requests of Standing Committees than would be possible were the members of the Standing Committees members also of the Executive Board. The new By-Law provides that those members of the Executive Board who were serving at the close of the Milwaukee session would have their choice of continuing with the Executive Board or continuing with the Standing Committee.

The new Executive Board, which

consists of the President, the President-elect, the Treasurer, and 6 other Fellows of the Association, includes 3 new members, Dr. J. N. Baker of Alabama, Dr. John P. Koehler of Milwaukee, Friend Lee Mickle of Connecticut, in addition to Dr. John L. Rice of New York, and Dr. Huntington Williams of Baltimore who were reelected. Dr. John A. Ferrell of New York has been elected Chairman of the Executive Board for one year. The vacancies on Standing Committees occasioned by this new By-Law will be filled at the December meeting of the Executive Board on recommendations submitted by the Chairmen of the Standing Committees.

Another important change in the By-Laws was made at the instance of the Committee on Fellowship and Membership as a result of a special study made of the grades of membership. In effect, this change does away with the former distinctions between active and associate members, creating instead a grade known as "member." Constituents from any country may be elected to this and to other classes of membership except that of "Fellow." Fellows must be professional health workers from the United States and its possessions, Canada, Mexico, and Cuba.

The former provisions of the By-Laws regarding members and associate members had attempted to distinguish between these two classes on a basis which did not prove practical in operation. A good many persons classified in one way at the time of entering the Association are now eligible for another class, and considerable confusion has arisen over this arbitrary distinction. At the same time that general membership is broadened, an effort will be made by the Committee on Fellowship and Membership to tighten up the requirements in the higher grade of Fellowship.

The Governing Council considered a

revision of the procedure for the nominations to the Governing Council, desiring that the representation on the Governing Council in the future might be more democratic and better distributed geographically. After much discussion, it was decided to leave this proposal on the table in such a form that it may be raised for action at the next Annual Meeting if, in the opinion of those interested, it would accomplish its purpose. There appeared to be no difference of opinion on the need for a better method, but there was a question in the minds of a good many members of the Council whether the ideal scheme had yet been found.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

T. F. Abercrombie, M.D., State Department of Health, Atlanta, Ga., State Director of Health
 Robert K. Galloway, M.D., M.P.H., Franklin, Tenn., Director, Williamson County Health Department
 Walter H. Hartung, M.D., State Office Building, Columbus, O., State Director of Health
 Bernard Hochfelder, M.D., Coushatta, La., Director, Red River Parish Health Unit
 Ferdinand R. Krembs, M.D., Stevens Point, Wis., Health Officer
 J. W. Lowe, M.D., Merrilan, Wis., Health Officer
 William J. Lutz, Route 9, Box 164, Milwaukee, Wis., Health Officer
 Charles H. Mason, M.D., 1302 Tower Avenue, Superior, Wis., Health Officer
 John A. McDonald, M.D., Eastport, Me., Washington County District Health Officer
 John C. McGuire, M.D., Hazlehurst, Miss., County Health Officer
 Michael J. Nester, M.D., 710 North Main Street, Providence, R. I., Superintendent of Health
 John Oberwager, M.D., 1327 Lexington Avenue, New York, N. Y., Sanitary Superintendent, New York City Department of Health
 Dr. Gral. Jose Siurob, Avenue Mariano Escobedo #59, Tacuba, Mexico, D. F.,

Mex., Head of Federal Health Department
 G. Colbert Tyler, M.D., City Hall, Newport News, Va., Health Officer
 Richard W. Weiser, M.D., 139 E. Hazeltine Avenue, Kenmore, N. Y., Medical Supervisor, City Public Schools
 Harry F. Wilson, M.D., C.P.H., Dillon, S. C., County Health Officer
 Dr. F. T. Younker, Galesville, Wis., Health Officer

Laboratory Section

Irving H. Borts, M.D., 817-7th Avenue, Iowa City, Ia., Bacteriologist, State Laboratory
 Frank W. Bouska, M.S., 1526 South State St., Chicago, Ill., Superintendent, Beatrice Creamery Company
 Cornelia L. Carey, Ph.D., Barnard College, New York, N. Y., Assistant Professor
 Gail M. Dack, M.D., Ph.D., 5724 Ellis Avenue, Chicago, Ill., Assistant Professor, Department of Hygiene and Bacteriology, University of Chicago
 Earl W. Flosdorf, Ph.D., 36 South Wyoming Avenue, Ardmore, Pa., Associate, Department of Bacteriology, School of Medicine, University of Pennsylvania
 Paul S. Galtsoff, Ph.D., U. S. Bureau of Fisheries, Washington, D. C., Charge of Oyster Fishery Investigations
 Lucy Heathman, M.D., Ph.D., State Depart-

ment of Health, Minneapolis, Minn., Assistant Director, Preventable Diseases Division

Betty S. Kolchin, 3 Research Laboratory, Ft. of East 15 Street, New York, N. Y., Bacteriologist

George F. Leonard, M.D., E. R. Squibb & Sons, New Brunswick, N. J., Bacteriologist and Immunologist

Charles S. McCleskey, Ph.D., Iowa State College, Ames, Ia., Bacteriology Teacher

Wayne N. Plastring, Ph.D., Storrs Agricultural Experiment Station, Storrs, Conn., Associate Bacteriologist

George E. Rockwell, R. F. D., Milford, Ohio, Associate Professor of Bacteriology, Medical College

Wilbert S. Slemmons, M.S., Oconomowoc, Wis., with Carnation Company

Gustav I. Steffen, Ph.D., 525 East 68 Street, New York, N. Y., Assistant Bacteriologist, New York Hospital

R. W. Titus, Ph.D., Marysville, O., Director of Research, Nestle's Milk Products, Inc.

John A. Toomey, M.D., City Hospital, Cleveland, Ohio, Physician in Charge

Oscar B. Williams, Ph.D., 1739 H Street, N.W., Washington, D. C., Bacteriologist, National Canners Assn., Research Laboratory

Vital Statistics Section

J. F. Blackerby, 532 W. Main Street, Louisville, Ky., State Registrar of Vital Statistics

Franklin H. Reeder, Jr., 410½ Nancy Street, Charleston, W. Va., Acting State Registrar of Vital Statistics

Public Health Engineering Section

Harold S. Adams, B.S., 213 North Sycamore Street, Marshall, Mich., Sanitary Engineer, Calhoun County Health Department

O. T. Birkeness, 605 W. Washington Street, Chicago, Ill., Sanitary Engineer, Wallace & Tiernan Company

Earl Devendorf, B.S., 1228 State Street, Schenectady, N. Y., Associate Director, Division of Sanitation, State Department of Health

Arthur B. Fergusson, 24 N. Sheppard Street, Richmond, Va., Chief Sanitary Officer

Ed L. Penfrase, 101 Park Avenue, New York, N. Y., Research work in Public Health Engineering

Robert R. Stewart, State Board of Health, Jefferson City, Mo., Engineer

Charles P. Tracy, 1118 Stewart Ave., Knoxville, Tenn., Director of Sanitation, City Health Department.

Industrial Hygiene Section

William H. Lehmberg, S.B., American Optical Company, Southbridge, Mass., Research and Development work on respiratory protective devices and dust quantitation instruments

Edward G. Meiter, Ph.D., Employers Mutuals, Milwaukee, Wis., Director, Industrial Hygiene Laboratory

Heymen R. Miller, M.D., 2 East 85 Street, New York, N. Y., Practice and consultation in Industrial Medicine

Food and Nutrition Section

Morris Ant, M.D., 277 Eastern Parkway, Brooklyn, N. Y., Physician

Henry Hoffmann, Jr., Rm. 552, State Office Bldg., St. Paul, Minn., Chief Chemist, Department of Agriculture

George H. Marsh, M.S., Department of Agriculture & Industries, Montgomery, Ala., Supervisor, Food and Drug Control

Morris Ostrolenk, B.S., U. S. Department of Agriculture, Food & Drug Administration, Washington, D. C., Bacteriologist

Child Hygiene Section

Elizabeth Andruszkiewicz, M.D., 2063 South 13 Street, Milwaukee, Wis., Child Welfare Physician

Frances A. Cline, M.D., State Board of Health, Madison, Wis., Staff Physician, Bureau of Child Welfare

A. Winnifred Golley, R.N., Box 94, Charlevoix, Mich., County Nurse, Children's Fund of Michigan

Reverdy M. Hall, M.D., 324 East Wisconsin Avenue, Milwaukee, Wis., Pediatrician, Milwaukee County Day Schools

Edythe P. Hershey, M.D., School Administration Building, Dallas, Tex., Director, School Health

Katharine F. Lenroot, B.A., Chief, Children's Bureau, Department of Labor, Washington, D. C.

Albert McCown, M.D., Children's Bureau, Department of Labor, Washington, D. C., Acting Director, Division of Maternal & Child Health

Mac C. Schroder, M.D., Bureau of Laboratories, Ft. of East 16 Street, New York, N. Y., Research Worker

Lendon Snedeker, M.D., M.P.H., 66 Commonwealth Avenue, Boston, Mass., Practising Pediatrics

Irene T. Stemper, 209 Woodland Lane, Oconomowoc, Wis., Examining Physician, Waukesha County Child Health Center

Nina Tomkiewicz, M.D., 920 North 15 St., Milwaukee, Wis., Child Welfare Clinic Physician

Public Health Education Section

Francis L. Bacon, LL.D., Evanston Township High School, Evanston, Ill., Principal
 Ruth L. Conrad, M.A., 1077 New York Avenue, Pasadena, Calif., Instructor, Bacteriology, Pasadena Junior College
 Elizabeth Dean, B.S., 6 Payne Place, Normal, Ill., Assistant Professor of Hygiene and Health Education, Normal University
 Walter F. Greenman, 320 Otis Street, West Newton, Mass., Member, Executive Committee, Massachusetts Tuberculosis League
 Alvin Powell, M.D., Lafayette, Calif., University of California, Dept. of Education

Public Health Nursing Section

Norma B. Eskil, R.N., 308 South Wilson Street, Royal Oak, Mich., Visiting Nurse, Detroit Visiting Nurse Association
 Eluore Hackmann, R.N., Marshfield, Mo., Webster County Public Health Nurse
 Hazel Hutcheson, Court House, Fargo, N. D., Supervisor, County Public Health Nursing
 Lulu J. Koepke, Benzon, Ariz., U. S. Public Health Service
 Lucille Morgan, R.N., 310 Grover Street, Warrensburg, Mo., Nurse, Central Missouri State Teachers College
 Margaret B. Purvis, B.S., 38 East Highland Avenue, Atlantic Highlands, N. J., Superintendent of Nursing Education, New York City Department of Health

Cecile O. Sparkman, Lewisburg Avenue, Franklin, Tenn., Williamson County Nurse
 Elsie B. Thomson, 145-95 Street, Brooklyn, N. Y., Supervising Nurse, New York City Department of Health
 Ethelyn Town, R.N., Jefferson, Wis., Jefferson County Nurse
 Esther C. Treadway, R.N., 2001 Warren Street, Winfield, Kans., City School Nurse
 Jane White, R.N., 820 Bush Street, Jackson, Mich., Supervisor, Public Health Nurses
 Edna L. Whitesides, P. O. Box 235, Columbia, Mo., Metropolitan Life Ins. Co. Nurse
 Ruth I. Wisnaes, R.N., 704-7 Street, Bismarck, N. D., State Supervisor Nursing Service, F.E.R.A.

Epidemiology Section

Floyd C. Turner, M.D., National Institute of Health, Washington, D. C., Surgeon, U. S. Public Health Service

Unaffiliated

Charles H. Eastwood, Wallace & Tiernan Co., Newark, N. J., Advertising Manager
 Dwight O'Hara, 5 Bay State Road, Boston, Mass., Professor of Preventive Medicine, Tufts College, Medical School
 George R. Wilkes, 3308 School Lane, Drexel Hill, Pa., Biological Department, The National Drug Company

HONORARY FELLOW ELECTED

AT the Milwaukee Annual Meeting, Dr. Gustavo Pittaluga, of Madrid, Spain, was elected to Honorary Fellowship in the American Public Health Association.

Dr. Pittaluga is Director of the Instituto Nacional de Sanidad, Chief of the Spanish Public Health Service, and Professor of Tropical Medicine and Hygiene in the University of Madrid Medical School.

SOUTHERN BRANCH, A.P.H.A.

THE meeting of the Southern Branch of the American Public Health Association, to be held at the Jefferson Hotel, St. Louis, Mo., November 19-20, will include a symposium on poliomyelitis.

AT THE MILWAUKEE MEETING

Dr. J. Offringa, the Director of the Public Health Service in Batavia, Dutch East Indies, was among the overseas visitors at the Milwaukee meeting.

Another distinguished visitor from abroad was Dr. Einar Rietz, the Health Officer of Stockholm, Sweden. Dr. Rietz presented a paper at the dinner of the Health Officers Section on the control of syphilis.

Dr. Angel de la Garza Brito, Supervisor General of the Departamento de Salubridad, Mexico, in attendance at Milwaukee was the official representative of the Federal Department of Health of which Dr. Gral. Jose Siurob is Director General. Dr. Brito was elected a Vice-President of the Association.

NEWS FROM THE FIELD

COMMISSION TO CODIFY HEALTH LAWS

A PUBLIC HEALTH commission to codify the health laws of the State of Massachusetts, eliminating those which are obsolete and revising others, was appointed by Governor Curley, August 21.

Henry D. Chadwick, M.D., State Commissioner of Public Health, member A.P.H.A., is Chairman of the Commission; Wilson G. Smillie, M.D., Professor of Public Health Administration, Harvard School of Public Health, Fellow A.P.H.A., is Vice-chairman; and Charles F. Wilinsky, M.D., Deputy Health Commissioner of Boston, F.A.P.H.A., is Secretary.

In addition to the codification of health laws, the Commission also will consider minimum standards for local health officers, the organization of county health districts, making a study of industrial hygiene, the licensing of hospitals, and milk control practices.

EIGHT HOURS FOR NURSES

UNDER the auspices of the Committee on Eight Hours for Nurses, District 13 of the New York State Nurses Association, there will be a Nurses Hobby Show, at the Hotel Biltmore, New York, on November 14-15.

The objectives are:

1. To present the hobbies of nurses and demonstrate the versatility of members of the profession.

2. To make available opportunities and resources for hobbies in New York City.

3. To stimulate widespread interest in the Hobby Show among doctors, hospital authorities, and the general public to the end that there will be more general recognition of the fact that nurses need leisure; that shortened hours of work will give them added zest and time for broadening interests which will reflect advantageously in their care of the sick.

INTEREST IN INFLUENZA

DR. RUFUS COLE, of the Hospital of the Rockefeller Institute for Medical Research, New York, has requested that state health officers notify him at the Institute of any fresh outbreaks of influenza which may occur.

There have been isolated in some recent outbreaks organisms which may stand in causal relationship to this disease and Dr. Cole wishes this advance information in order that further studies can be made.

COURSE IN PUBLIC HEALTH TEACHING

A FOUR-YEAR integrated curriculum in public health teaching has been established at George Washington University School of Medicine, Washington, D. C., to parallel its curriculum in mental health established 3 years ago under Dr. William A. White.

The public health course has been made a part of the regular medical course for the degree of doctor of medicine but is open also to special and graduate students in the public health field. Courses in community health, sanitation, hygiene, preventive medicine, and the public health aspects of medicine and surgery are included. —*J.A.M.A.*, Sept. 28, 1935, p. 1044.

CRIPPLED CHILDREN REHABILITATION PROGRAM IN SOUTH CAROLINA

THE South Carolina Society for Crippled Children and the South Carolina State Department of Health have launched a state-wide program for rehabilitation, with district headquarters in Greenville, Columbia, Florence, and Charleston.

Clinics will be held weekly in these cities and in Spartanburg.

A committee consisting of Dr. Lesesne Smith, of Spartanburg, Dr. Julian P. Price, of Florence, and P. G. Sherer, Chief of the Division of Vocational Rehabilitation in the State Department of Education, is in charge of the program, which is financed by funds raised by the society and by money available to the State Health Department for orthopedic work.

MASSACHUSETTS HEALTH SURVEY

THE share of Massachusetts in the \$3,450,000 appropriation for a nation-wide public health survey will be \$162,000. A house-to-house canvass will be made to determine the prevalence of chronic diseases.

Sample groups of certain income levels will be studied in this national survey, sponsored by the U. S. Public Health Service and carried out by the Works Progress Administration. Medical facilities for the care of the sick will be studied.

NEBRASKA HEALTH SERVICE CREATED

THE Omaha-Douglas County Central Health Service was incorporated August 1.

The new organization aims to enable persons of low income to obtain medical service at a cost within their financial means, establish a friendly doctor-patient relationship, aid the physician in the collection of fees, and prevent those persons from receiving free clinic care who can afford to pay for medical service.

The incorporators of the new service are Dr. Frederick O. Beck, Dr. E. H. Bruening, and Dr. John Jay Keegan, all of Omaha. The headquarters will be in Omaha, Neb.—*J.A.M.A.*, Sept. 14, 1935.

MINNESOTA HEALTH SURVEY

OF the \$3,450,000 federal allocation for a national public health survey, Minnesota will receive \$108,-

500 to carry out its studies, it is reported.

A house-to-house canvass will be made to determine the prevalence of chronic diseases; physical examinations will be given; and studies of medical facilities will be carried out.

BROSS PRIZE

A PRIZE of \$15,000 will be awarded under the Bross Foundation, established at Lake Forest College, Lake Forest, Ill., in 1879, by William Bross in memory of his son Nathaniel.

Known as the Bross Prize, the award will be given for the best book or manuscript heretofore unpublished on the connection, relation, and mutual bearing of the humanities, the social sciences, the physical sciences, the biological sciences, or any branch of knowledge with and on the Christian religion. The award will be made on January 1, 1940.

William Bross was a former (1865-1869) Lieutenant-Governor of Illinois and a Trustee of Lake Forest College for 26 years. With J. L. Scripps, Joseph Medill, Alfred Cowles, and others, he was founder of the *Chicago Tribune*.

In 1925 the prize went to Douglas C. MacIntosh, Yale University Professor. Other winners have included a Scotsman and an Englishman. Distinguished men who have lectured at Lake Forest College under the Bross Foundation have included Professor Marcus Dods of New College, Edinburgh, Scotland; Professor J. Arthur Thomson of the University of Aberdeen, Scotland; Dr. Frederick J. Bliss of Beirut, Syria; Reverend John N. Figgis of Mirfield, England; Professor Henry W. Wright of the University of Manitoba, Canada; Dr. M. Bross Thomas of Lake Forest.

"The offer must be open to scientific men, the Christian philosophers and historians of all nations."

Those entering the competition may have until September 1, 1939. They are to submit their manuscripts of a minimum of 50,000 words.

NEW MEXICO DISTRICT HEALTH OFFICERS

HEALTH work in New Mexico has been organized into 10 districts, each under the supervision of a full-time health officer.

Nine health officers have already been appointed, with headquarters as follows:

Elroy F. McIntyre, M.D.,* Santa Fe
 Edgar B. Beaver, Gallup
 James R. Scott, Ph.D.,† Albuquerque
 Charles W. Gerber,† Las Cruces
 William W. Johnston, M.D.,† Las Vegas
 Owen E. Puckett, M.D.,* Carlsbad
 Frank W. Parker, Jr., Silver City
 Julian O. Long, Los Lunas
 Leonard A. Dewey, Clovis (temporary)

* Member, A.P.H.A.

† Fellow, A.P.H.A.

CHANGES IN PUBLIC HEALTH SERVICE

IT has been announced that the following members of the U. S. Public Health Service have been promoted and commissioned as medical directors in the regular corps of the service:

James P. Leake, M.D., F.A.P.H.A.
 Lawrence Kolb
 H. E. Hasseltine, M.D., F.A.P.H.A.

Dr. Hasseltine was recently relieved of his duties at San Francisco, Calif., and assigned to Carville, La., in charge of the U. S. Marine Hospital.—*J.A.M.A.*, Sept. 28, 1935, p. 1047.

PUERTO RICO PERSONALS

EIGHT Puerto Ricans were recently designated by Eduardo C. Morales, M.D., Dr.P.H., Commissioner of Health of Puerto Rico, F.A.P.H.A., to receive fellowships granted by the Rockefeller Foundation's International Health Division for study in the United States. They are:

Dr. Norberto A. Quinones, who will study bacteriology

Dr. Juan Basora and Dr. Victor J. Montilla, public health

Dr. Abel de Juan, vital statistics and epidemiology

Dr. Jose R. Vivas and Dr. Libertad R. Gaetan, tuberculosis

Winifred M. Mendez and Carmen L. Rivera, public health nursing

It has been announced that Joseph H. Axtmayer, Ph.D., has recently returned to the School of Tropical Medicine of the University of Puerto Rico, conducted under the auspices of Columbia University, after a year of research in biologic chemistry at the University of Rochester; and Luis Hernández has returned from special study in clinical pathology at the University of Michigan Medical School, Ann Arbor.

Other members of the faculty who are studying in the United States and Europe include: Dr. Enrique Koppisch of the Department of Pathology, who is at Basel, Switzerland, studying filtrable viruses on a fellowship from the Rockefeller Foundation; Luis M. González, at the Henry Phipps Institute of the University of Pennsylvania, Philadelphia, Pa., for study of tuberculosis; Americo Pomales-Lebrón, at the University of Michigan for a doctorate in bacteriology; Dr. Rafael Rodriguez-Molina and Felix Lamela, at the University of Chicago, for courses in hospital management and administration.—*J.A.M.A.*, Sept. 21, 28, 1935, pp. 975, 1046.

PERSONALS

LEONARD GREENBURG, M.D., Fellow A.P.H.A., has resigned his position as Health Officer of New Haven, Conn., effective October 15. He has been appointed Executive Director of the Division of Industrial Hygiene, New York State Department of Labor. He has already

taken up his new duties and will have his office in the State Office Building, 80 Center Street, New York City. Dr. Greenburg has been identified with the Industrial Hygiene Section of the A.P.H.A. for many years and has been connected with the Department of Public Health at Yale University.

DR. ANDREW J. HAMILTON has been appointed Health Officer of Rison, Ark.

DR. JOSEPH L. BRYAN, of Xenia, Ill., has been appointed Health Officer of the district including Clay, Effingham, Jasper and Crawford Counties.

DR. JOHN A. McDONALD, of East Machias, Me., has been appointed District Health Officer.

DR. CHARLES F. MCKHANN, Assistant Professor of Pediatrics and Communicable Diseases, Harvard Medical School, Boston, Mass., has gone to China, where he will be Visiting Professor of Pediatrics at Peiping Union Medical College during the first half of the school year 1935-1936. He will return to Boston early in March, 1936.

DR. MELVIN L. HUTCHESON, of Denton, Tex., has been appointed Health Officer of Denton County, succeeding Dr. James H. Hicks.

DR. ELBERT W. WRIGHT, of Bowie, Tex., was recently elected Chairman of the Texas State Board of Health, succeeding Dr. Charles M. Rosser, of Dallas.

WALTER M. DICKIE, M.D., of Berkeley, has been re-appointed Health Officer of the State of California. Dr. Dickie had held the position from August, 1920, to 1931, when he was succeeded by Giles S. Porter, M.D., F.A.P.H.A. Dr. Dickie succeeds J. D. Dunshee, M.D., F.A.P.H.A., who resigned.

CLAIR E. TURNER, DR.P.H., Professor of Biology and Public Health at the Massachusetts Institute of Tech-

nology, Cambridge, Mass., Fellow A.P.H.A., has been invited by the University of Calcutta, India, to deliver a series of 6 lectures on the organization of health education.

EARLE G. BROWN, M.D., of Topeka, Kans., F.A.P.H.A., Health Officer of Topeka from 1919 to 1925, and since 1925 Secretary of the Kansas State Board of Health, has been appointed Professor of Hygiene and Preventive Medicine at the University of Kansas School of Medicine, Kansas City, Kans.

DR. ALIX CHURCHILL, Associate Secretary-General of the International Association for Prevention of Blindness, and Executive Secretary of the International Union Against Tuberculosis, recently arrived in the United States for a series of conferences in various cities on policies and procedures in the world-wide fight against blindness and tuberculosis. Dr. Churchill is the guest of the National Society for the Prevention of Blindness and the National Tuberculosis Association.

FRANK P. STROME, M.D., of the Harrisburg Department of Health, member A.P.H.A., has been appointed Chief of the Bureau of Vital Statistics of the Pennsylvania State Department of Health, to succeed Dr. William E. Matthews, who had served 46 years.

GEORGE A. HAYS, M.D., formerly with the Missouri State Board of Health, Jefferson City, Mo., has been appointed State Epidemiologist of Arizona, with offices in Phoenix. He succeeds Hugh F. Stanton, M.D., C.P.H., resigned. Both Dr. Hays and Dr. Stanton are members of the A.P.H.A.

CLELAND A. SARGENT, M.D., of Dover, Del., member A.P.H.A., for many years Director of Communicable Disease Control and Director of Infant and Maternal Hygiene in

the Delaware State Board of Health, has been provisionally appointed epidemiologist with the New York State Department of Health.

DR. PHILIP I. CREW has been appointed Health Officer of Marion, Ia.

DR. JOYCE I. HARTMAN has been appointed Supervisor of Health Education in the Cleveland, Ohio, public schools, succeeding Lyman W. Childs, M.D., member A.P.H.A., who had held the position since 1910.

DR. F. FLOYD SOUTH, and DR. ARCHIE C. VAN CLEVE, of Portland, Ore., have been appointed to the Oregon State Board of Health, to succeed Dr. Albert Mount, of Oregon City, and Dr. Joseph P. Brennan, of Pendleton, respectively.

DR. EDWARD J. FINN has been appointed Health Officer of Shelton, Conn., succeeding Dr. Francis I. Nettleton.

DR. JOHN D. MILBURN has been named Health Officer of East Hampton, Conn., to succeed the late Dr. Frederick T. Fitch.

DR. JOSEPH DAVID ARONSON, of the staff of the Henry Phipps Institute of the University of Pennsylvania, Philadelphia, Pa., has been appointed special expert on tuberculosis in the Indian Service under the Department of the Interior. He has been granted leave of absence from the Institute and has established headquarters in Albuquerque, N. M., from which he will direct a study of opportunities for preventive work against tuberculosis in New Mexico and Arizona Indians. After several weeks he will make similar observations on the Blackfoot and Crow Indians in Montana. Dr. Aronson is assistant professor of bacteriology at the University of Pennsylvania School of Medicine. Dr. Esmond R. Long, Director of Phipps Institute, has again been appointed

special consultant on tuberculosis; in this capacity he made a survey of the Papago Indians for the Indian Service last winter.

DEATHS

CLARENCE W. BUCKMASTER, M.D., member A.P.H.A., for 15 years Commissioner of Health of Yonkers, N. Y., died on October 7. He specialized in contagious diseases and his efforts won for Yonkers a national reputation for its low death rate. He organized an immunization campaign in 1927 which lowered the city's diphtheria total from 438 cases in that year to 3 cases in 1933. He was 63 years of age.

ALBERT PFEIFFER, M.D., Director of the Division of Social Hygiene in the New York State Department of Health, Albany, N. Y., died September 24, at the age of 53.

J. FRED ECKERSON, M.D., of Shelby Center, N. Y., died recently. Dr. Eckerson had been Health Officer of Shelby since 1904.

WALTER TREAT WALKER, Vice-president-in-charge-of-sales of the Kimble Glass Company, of Vineland, N. J., died at White Sulphur Springs, W. Va., on October 2.

JOSEPH C. BLOODGOOD, M.D., of Baltimore, Md., member A.P.H.A., died suddenly on October 22. He was Adjunct Professor of Surgery at the Johns Hopkins University School of Medicine. He also was on the staff of the Johns Hopkins Hospital and was chief surgeon at St. Agnes's Hospital, as well as head of the Hopkins Laboratory of Surgical Pathology. He was active in the fight against cancer.

CONFERENCES

Nov. 1, Mid-Year Meeting of the New York State Association of Public Health Laboratories, at the State Laboratory, Albany, N. Y.

Public Health

A Problem in Distribution^{*}

WALTER H. BROWN, M.D., F.A.P.H.A.

Professor of Hygiene, Stanford University, Palo Alto, Calif.

THE address by your President-Elect at this time marks a departure from an established custom of the Association. In past years, it has been the duty of the President to report to you upon the state of the Association and present his recommendations for the future at the end of his term of office. It was his "swan song."

This new practice of permitting the incoming presiding officer to present his views at the beginning of his service has both advantages and disadvantages. It affords him an opportunity to indicate his evaluation of public health problems of the day and also assists in securing action upon them by the Association. On the other hand, it detracts somewhat from the objective point of view that would be possible at the end of his term.

Our retiring President, Dr. Bishop, has relieved me of the responsibility for reporting upon the state of the Association, and has presented a clear-

cut picture of many of the important problems before us. This leaves me free to devote the time at my disposal to a discussion of some fundamentals that need reconsideration if public health is to retain its rightful place in the new order of society.

As a background for our discussion it will be profitable to recall the great lag between our present knowledge of the cause, cure, and prevention of disease and the degree of success in securing an application of this knowledge. Within the lifetime of the Association, modern scientific investigation has placed in our hands the tools for the control of many of the communicable diseases, and has blazed the trail that will lead to the discovery of the causes and methods of control of the remaining ones. The complex and hidden causes of non-communicable diseases—such as heart disease, nephritis, and cancer, are yielding sufficient of their secrets to permit successful attacks upon them. We do not lack the knowledge of ways to reduce infant and maternal mortality. Even the difficult problem of mental diseases has reached the stage where cure is possible and prevention is often within our grasp.

^{*} Address of the President-Elect delivered at the Second General Session of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935.

This is not a mere enumeration of theoretical statements gleaned from the proceedings of scientific societies. It represents what has been shown to be true wherever qualified public workers have been given an opportunity to secure application of this health knowledge. There is no need to prove such a statement for this audience. You are engaged in demonstrating its truth in your daily work. There is need, however, of raising the question as to why your demonstrations have not resulted in a wider distribution and more stable maintenance of public health services.

It may be useful for us to remind ourselves of some rather unpleasant facts. Notwithstanding our creditable progress during the last decade, a large percentage of the population of our country remains without essential public health services. The qualifications, tenure, and salaries of our health workers are far from satisfactory. Partisan politics all too frequently dominates the appointment of the official, as well as administration and tenure of office. Our budgets for health service are small compared with other governmental agencies. Even these inadequate appropriations have been cut during the depression to the point of destruction of many essential services. Finally, and perhaps of greatest significance, no spontaneous protest has arisen from the public. You may charge me with painting a dismal picture. I am sorry, but these are facts. Our most important duty at this time is to face facts, if we are to plan wisely for the future.

The first step in this procedure would seem to be a critical analysis of the factors underlying these conditions. Our basic problem is finding more successful methods for securing a wider distribution of what biology, medicine, and administration have taught us will protect and improve human health.

Therefore, I invite you to consider

with me the topic: "Public Health—A Problem in Distribution." In common with our industrial confrères we have produced a great wealth of valuable products but have failed to secure adequate methods for equable distribution.

The essentials of a public health program that we now accept are the result of many years' experience of our leading health workers, crystallized and made practical through the constructive work of the Committee on Administrative Practice. In the field of federal and state services the details are not so clearly defined. There is need, as we will take occasion to point out later, for further clarification in this area. However, there can be no disagreement as to what the essential factors are that make possible a sound public health program in any field. We would enumerate them as: sufficient legal power to permit effective administration, adequate budgets, properly trained personnel, and intelligent public support.

It would seem superfluous to discuss sufficient powers with this group. Yet, the most casual analysis of barriers that obstruct the progress of public health reveals the difficulty that arises from the lack of powers—legal or administrative. We shall continue to suffer from instability in our public health services as long as they are not based upon sufficient legal powers.

The necessity for adequate budgets in order to permit satisfactory service is self-evident. The situation in this field is anomalous. We know the cost of the technical procedures that will prevent unnecessary illness and premature death. The price is ridiculously low as compared with other public services. Yet, year after year the health services of this country, with few exceptions, are supported upon the poverty level. We have been too modest both in our claims as to the

worth of health services and in our demand for appropriate financial support. Adequate public health programs demand budgets commensurate with the health needs of the community.

Public health has become a specialized field. Its problems require a high degree of technical knowledge and skill for their successful solution. This important fact is being tardily recognized by those who control the organization and administration of health services. This is one of the explanations of the present unsatisfactory status of qualifications, tenure, and salaries of health workers. It has deterred many capable individuals from entering the field of public health.

The inclusion of intelligent public support as an essential to satisfactory public health service needs no justification. Unfortunately, we have not been able to command it to any great degree. All too frequently our support has been based more upon emotion than upon reason because we have concentrated our attention on health service to the individual and neglected to educate him and demand public support for such services. The results have been manifest in the inertia of the public while essential health services, in many places, were either abolished or reduced to a poverty level. We cannot hope to maintain a high degree of health service until we find the way to secure and maintain intelligent public support for our programs.

These, then, may be accepted as essential factors necessary if we are to provide adequate public health services for all of the population. Let us have them clearly in mind as we review briefly the present status of our facilities for and methods of distribution.

It is not my purpose to discuss details of present public health programs. I desire to review briefly the administrative mechanism we have developed

for securing distribution of the benefits of modern scientific knowledge in the field of health. More particularly, my aim is to analyze these mechanisms for the purpose of determining where and how they may be improved. To this end we shall examine certain features of the official and voluntary health agencies and their relationships to the private practice of medicine.

An analysis of the present system of organization and administration of official health agencies reveals a wide variation in methods and effectiveness.

We find health functions of the federal government scattered through a considerable number of departments or bureaus. This system does not make for coördination since it depends too often for satisfactory relationships upon the spirit and personalities of the executives. Further, we find the usefulness of federal agencies frequently limited by lack of direct power within the states. One sees many instances where federal assistance properly applied would bring marked improvement in health services. Notwithstanding these handicaps, the assistance of federal agencies in solving state and local health problems has gradually improved under the guidance of skilled administrators. The question I desire to raise is what further steps are necessary in order to gain the highest potential benefits.

The status of state health organization and administration is of particular importance at this time, for if we are to be successful in securing a satisfactory widespread and permanent distribution of health services, it will require strong, well administered state health departments.

The variations in type of organization and administration of state health departments are characteristic of public health in the United States. Since each state is the sole judge of its own health needs, wide variations of

methods are inevitable. To a certain degree, this is desirable. The result, however, has been an uneven distribution of health services. We have not developed satisfactory standards for state health administration and there is but poor definition of the basic functions by statute.

As was indicated in the President's address, it is in local health administration we have made our most consistent and rapid advances. We have a well defined pattern of essential services required and standards by which such services can be evaluated. We know what they will accomplish and how much they will cost. Further, we have had numerous examples of how they can be successfully distributed to the ultimate consumer. We even have a few instances where they are so intelligently backed by public opinion that the depression did not interfere with them. The work of the Committee on Administrative Practice has been an important contributing factor.

Let us turn now to a brief consideration of the present status of three essential elements common to all units of health administration—legal powers, personnel, and budgets.

Variations in the laws under which official health services operate in the United States are of significance. An analysis of them reveals how far away we are from the attainment of a statutory basis that would be acceptable on a national scale.

Complete uniformity is neither necessary nor desirable. Sufficient power for properly controlling the organization of departments and securing effective carrying out of their programs is fundamental. I do not refer merely to enforcing of laws, though this is of importance. I do refer to the necessity for providing such powers as will reduce to a minimum the possibility of the domination of health services by political or other self-interest groups.

To amplify what Dr. Bishop has pointed out, methods of appointment, qualifications, and tenure of office of health personnel are far from satisfactory. The regular federal services are exceptions to this statement. While considerable progress has been made in placing certain grades of health workers under civil service, frequently important positions are filled without due regard for technical qualifications and without any guarantee of permanency of tenure. This will have an important influence upon the proposed expansion of official public health programs through federal aid.

It is difficult for me to speak temperately with reference to health budgets. Our record of inadequate health appropriations is a sad commentary upon our social judgment. Gradually health budgets were increased and services extended. The studies of Dublin, Shepard, Walker, and the Association tell the details of the story. They need not be recounted here. Reductions of budgets ranged from 5 per cent to the elimination of entire appropriations for some county units. In other places essential services were crippled or discontinued; all this with little or no protest from the public.

Such an episode almost compels us to seek an explanation of its causes. Certainly public health expenditures are not exorbitant when compared with appropriations for other public services. No informed person would say that the actual expenditures for health were excessive when compared with accepted standards for adequate services. The 90 cities entered in the Health Conservation Contest expended only \$.75 per capita in 1933. These figures are for cities which have shown a real interest in public health. The average expenditure for county health services is approximately \$.38 per capita while the state health appro-

priations averaged \$.13. Dublin summed up the matter in his Presidential address:

Altogether, we are spending something like 120 million dollars, or about \$1 per capita for health work of all kinds whether administered by official or private agencies. This is the amount which in the hey-day of public expenditure was allocated for this important service. On its very face, this amount is only a fraction of what is needed. The modest estimates prepared by our Committee on Administrative Practice call for appropriations of \$2.50 per capita if a well rounded program is to be maintained. In the counties, where health work is more difficult to conduct because of the distances to be covered, the expenditure to be adequate should be nearer \$3 per capita. In other words, *our expenditures in the past have never reached more than from one-half to one-third of what we could spend profitably.* There has been no wild development and no tendency to grow too fast. Very few communities have ever spent enough to derive the great benefits that sanitary science and modern medicine have made possible. It is with meager amounts indeed, that genuine achievements in disease control have been accomplished. We are still very far from where we can afford to cut down on public health work.

Excessive public health expenditures—either actual or relative—cannot account for unusual and unwise reduction in health budgets during a period when adequate health service was most needed.

This brings me to a consideration of voluntary health agencies. The evolution of these organizations has been one of the striking characteristics of the American scene. We find ourselves with a multiplicity of national and local voluntary groups engaged in some aspect of health service. Their total budgets amount to large sums. They enlist the services and interest of great numbers of trained and untrained workers. Sometimes they fail to act in harmony with the official agency. The policies, objectives, and methods of these organizations are frequently criticised. The opinion is held

by some that they have no further place in our public health program. It seems wise to discuss this opinion briefly.

Official agencies are not yet prepared with powers, personnel, or budgets to assume the useful public health functions now conducted or supported by these agencies. I am convinced that for many years to come, if not permanently, there is a useful and necessary function to be performed by independent, privately financed, properly conducted volunteer health agencies.

The protection of public health is essentially an official responsibility and we should encourage the adoption of and support for all essential health services under official responsibility as rapidly as possible. I am convinced there is much need for better coördination of some voluntary agencies with the official departments. These facts do not reduce the value of privately supported health organizations which have been and are being conducted in accordance with sound principles. In many places the volunteer agency is the only organized support of the health officials.

This statement is not intended as an approval for the indiscriminate organization and operation of national or local volunteer agencies. It would seem desirable for us to encourage the continued operation of those volunteer health agencies which are performing an essential service with proper relationships to the official agency. We might profitably bend our efforts toward securing better mechanisms for coördination of all health agencies and *seeing to it that they function.*

We come now to another important method for the distribution of health services. I refer to the private practice of medicine, specifically in its relationships to the programs of official and nonofficial health agencies. We

have in America the largest group of well trained medical men in the world; a system of hospitals and clinics second to none; and good educational facilities for undergraduate and postgraduate education in medicine.

In an era of organization and group activities, the age-old methods of individualistic practice of medicine are undergoing a severe test. The medical profession is making a valiant and highly commendable struggle to preserve all of the finest traditions and ideals of its honorable heritage. To these efforts we, as public health workers, pledge our heartiest support.

The growth and development of the American Medical Association is a splendid example of good organization. It has gradually expanded its program to meet the professional needs of its membership. This has made its present activity in the field of medical economics and public health relationships one of its primary functions at the present time. We are concerned particularly with the influence of medical-public health relations upon public health programs.

The diagnosis and treatment of disease have been the primary concern of the medical profession for centuries. Recently prevention has begun to occupy a more important place. Conversely, the public health profession has been primarily concerned with prevention and only incidentally with diagnosis and treatment. This situation has led inevitably to the time when the interests and activities of the two groups come into contact—either to merge or to conflict. This time has now arrived. The intelligent solution of this complicated and delicate issue is vital to both the professional groups and the public. The inherent objective of both groups is preservation and promotion of the health of individuals. The problem seems to be one of discovering better mechanisms for under-

standing and coöperation between professional organizations. I am convinced that they may be found.

This concludes a hurried and imperfect review of some essential factors necessary if we are to procure reasonably adequate health services. I trust it is understood that there is continued need for research leading to the discovery of improved methods of disease control and health promotion. I hope, however, that I have convinced you that our most important immediate task is the perfecting of methods for securing distribution of health services.

The time has arrived when we need a comprehensive, coherent national plan and policy for public health service. It should be sufficiently elastic to provide for a wide variation in the needs and conditions of the various geographic, political, and social units of our country. The public health workers, official and voluntary, are capable of devising such a plan and policy for discussion, modification, and final adoption. This is no short-time job, to be accomplished between two Annual Meetings of the Association. It demands a careful, painstaking review and evaluation of every aspect of health service. It calls for the wise use of our accumulated experience in every field of health. It needs to be a product of the best thinking of all professional groups. I make the proposal that we attempt to outline a coherent national health plan and policy with a full realization of its scope. I have considered the time needed and the work involved in bringing such a plan to its completion. Nevertheless, my earnest recommendation is that we make a beginning in order that we may develop an adequate integrated public health program for our nation.

The need for such a plan and policy is forcibly brought to our attention by the latest developments in our political life. We have devoted a special session

in this meeting to "Public Health in a Program of Social Security." Our retiring President has given us a thought provoking consideration of possibilities of the Social Security Act; and distinguished representatives of the federal services have presented tentative plans for its operation. These discussions signalize one of the most striking changes in public health history during the life of this Association.

The important task in public health administration of the immediate future will be the adjustment of federal, state, and local health relationships. The Social Security Act will make available greatly increased finances for public health service. Funds will be distributed on the well established principle of federal aid to states under definite conditions provided by the act.

The increased participation of the federal government in state and local programs requires careful adjustment. There should be no difficulty in establishing a proper relationship between the agencies that will permit ample local autonomy and, at the same time, assure sound, efficient local administration and programs. This presents a rare opportunity to raise the standards of public health practice as well as to extend such services.

We are assured that the keynote of the administration of the Security Act will be flexibility. This principle has demonstrated its worth in the hands of our federal agencies and some of our foundations. We look with confidence to the vision and wisdom of our official leaders in discharging their great responsibility, and pledge them our whole-hearted support.

Another important trend in public health administration is discernible in the rapidly changing socio-political picture. We refer to the inclusion of medical relief as a responsibility of the official health department. There is little disagreement as to the social duty

for the care and medical treatment of the indigent or even those persons otherwise self-supporting who are unable to provide themselves with medical care. There is a question in the minds of highly qualified health administrators as to the wisdom of including this responsibility among the duties of the health department. In my opinion, we should give judicious consideration to both aspects of this problem.

One phase of the matter was ably presented by a distinguished state health officer. The point was stressed that "health departments are better fitted by training to administer medical care given at public expense than are the welfare departments." Prevention and cure were considered as a unit problem and proposals made that state and local health departments be given responsibility for both functions.

Another angle which merits equally careful consideration comes from an experienced and skillful local health officer. He says, "Close coöperation between health activities and charity is essential—but while the two functions are linked together, they still remain *two* functions, separate and distinct, and it behooves the health department which seeks to maintain its true entity to consider well how it may preserve this free from public confusion." He outlines what are now considered to be the essential services for which the health department is responsible. He expresses a concern that if the administration of medical relief is added to these responsibilities, it will increase the friction between medical and public health professions and relegate the preventive program to a secondary position. Each of these points of view represents the opinion of a capable public health leader. Together they raise an issue that will have much to do with the character of official health programs of the future.

We should weigh this matter care-

fully in order that our health programs shall produce the maximum good. It may be that the next stage of our social evolution will require the extension of public health programs into the field of medical care. Perhaps no one plan can meet the widely differing social, economic, and professional conditions of our country. I am convinced, however, that additions to our present public health programs should not deflect our attention from the primary responsibility for the control of communicable diseases, sanitation, infancy and maternity service, school hygiene programs, and public health education.

The reference above to medical care leads naturally to a matter which calls for immediate and definite consideration. I refer to proper relationships between the medical and public health professions. Social objectives of both groups are identical—the protection, maintenance, and promotion of health of every individual. Your speaker is one of those who believe that *there are no insoluble problems* of relationships between the two professional groups.

He is convinced that it is a matter of adequate, continuous contact between the leaders of these groups on all matters of policy and program. This could be accomplished by a reciprocal representation on the governing bodies of the two associations. This plan would result in an opportunity for mutual understanding and discussion of policies and plans of the organizations at a time when this would be most effective.

May I urge the medical and public health leaders—national, state, and local—to consider this matter and to approach its solution in a spirit in keeping with the traditions and ideals of both groups.

Health education is another problem that should occupy our attention in the immediate future. A frank evaluation

of present methods and objectives in this area is clearly indicated. Health education has come to be a term with which to conjure. It is used indiscriminately to describe the activities of the quack, commercial interests, and the educator. Unfortunately the laity has great difficulty in separating the wheat from the chaff. This situation is one of the primary reasons why we do not secure intelligent, consistent public support for health programs.

It would be profitable to attempt bringing about a clarification of objectives and an integration of the activities of those legitimately engaged in health education programs. This should include official health and education departments, voluntary agencies, and the organized medical and dental professions. It has become increasingly apparent that no one of these groups can pursue its own projects independently.

With a common objective as a starting point, it would be possible for national, state, or local agencies to fuse their educational activities into a unified health education program. This would bring about greatly increased effectiveness for each participating agency without any loss of group integrity. Of even more importance, it would result inevitably in an increase of public confidence in the advice, proposals, and activities of all organizations.

It would appear that this is a particularly propitious time to attempt a coalition in this field.

It is my desire in the closing section of my remarks to call your attention to some of the ways in which the Association may contribute to a better distribution of health service. The first is searching for methods by which our Association can better serve the professional needs of all public health workers. This statement is not intended as an implied criticism of the

past efforts of either individuals or committees to provide such services. It is meant to express my conviction that the time has arrived once more for us to review the development of our organization as a guide for future action.

In 1929 we revised our Constitution. At that time we entrusted the major responsibilities for the direction and control of our affairs to a strong Executive Board of five standing committees. Five years of operation have demonstrated the essential soundness of this decision. Notwithstanding handicaps of readjustment and finances, we have made substantial progress in practically every division of our activities.

It would be a mistake, however, not to exercise continuous care and assure adequate, satisfactory representation of all groups on the governing body and committees. An Amendment to the By-laws was passed at this session to correct one such situation that has caused some dissatisfaction. A wider participation of our membership in the technical and administrative affairs of the Association would tend to strengthen the organization and train leaders for future responsibility.

We are glad to express gratification that it is possible to return to the practice of having a full-time Executive Secretary. The expanding interests of the Association require the undivided attention of a well qualified, and enthusiastic executive. In my opinion, the Executive Board has chosen such an individual in Dr. Reginald M. Atwater. We look forward to a period of increased activity under his administration.

In his presidential address in 1926, Winslow said: "The American Public Health Association has progressed almost as far as is possible along its present lines as a primarily national or rather international organization. Its

future depends upon the development in every state of the Union and in every province or other corresponding administrative district of Canada and Cuba and Mexico of strong local branches bound to the parent Association by membership and joint collection of dues."

I can do no better than to adopt this statement as my own with the plea that we endeavor also to bind these regional organizations to the parent association with ties of professional service. Those of us who come from the West Coast realize keenly how necessary these ties are. The live interest of the parent Association in the Western Branch has created a feeling of solidarity in that region which is essential for the health and strength of our national organization. We hope that renewed efforts will be made to extend such regional and local organizations.

The Committee on Fellowship and Membership has a difficult assignment. Their report of another gain in membership this year is gratifying. A study of their activities shows that they have year after year appealed to all groups by every approved method for assistance in increasing our membership. Yet an undesirably large number of public health workers remain on the eligible list. The committee cannot do this job alone—it needs the *active* coöperation of every member of the Association.

The growing complexity of the Annual Meeting presents difficulties for the Committee on Meetings and Publications. The increased number of speakers, with demands for more, rather than fewer, scientific sessions has rendered simplification almost impossible. The committee is hard pressed to supply conveniently located meeting rooms. The selection of the Annual Meeting place grows more trying each year. This matter deserves

constructive thought and active coöperation of the sections with the committee. We must not discourage the healthy expansion of scientific activities. We should avoid the meetings becoming so unwieldy as to reduce their effectiveness or seriously limit the parts of the country in which the meeting can be held.

We celebrated the 15th birthday of the Committee on Administrative Practice at this session. We look to it for continued leadership in its vital task of raising the standards of public health practice and stimulating the extension of public health services.

The survey of the State of Massachusetts which they are to conduct with the coöperation of the Commonwealth Fund indicates that they are to study state public health practice. They will, no doubt, coöperate with the State and Provincial Health Authorities in the development of methods for the promotion of improved facilities for state health departments to meet their enlarged responsibilities, for, if national participation in regional health activities on an increased scale is to be effective, it will hinge upon the effectiveness of state health departments.

I heartily endorse Dr. Bishop's statement regarding the work on the Committee on Research and Standards.

Before concluding my remarks, I wish to consider with you the training of health personnel and their professional qualifications. A study of our present educational facilities indicates that they are inadequate and poorly distributed. We have a number of well equipped schools of public health and many effective courses for training specialized workers.

It would be wise to develop training centers on a regional basis. The courses offered should be planned to meet the needs of all grades of workers in every essential line of public health service. The levels of training should

range from short courses to those leading to degrees or certificates with concentration in a special field of activity.

In planning these centers, use should be made wherever possible of the already established schools and the courses now being offered at various institutions. It is expected that the plans outlined by the Public Health Service under the Social Security Act will go far toward the solution of this problem.

Standards of professional qualifications for *specialist* in public health are needed. The Committee on Professional Education has been at work 3 years on this complex problem. Its activities have been conducted through sub-committees representing the various specialties. Agreement upon minimum educational standards has been reached in some groups. Others are only beginning discussions. In one instance, the problem is so complicated that further discussion is needed to reach a satisfactory solution.

We might consider the experiences of our medical and dental confrères in their struggles to raise professional levels. It proved necessary, and also wise, to erect their first technical standards upon the qualifications of those already engaged in practice on a creditable level. This might be a useful principle if applied to public health workers.

We should make every effort to raise the personal and professional qualifications for all health workers. It will require unusual wisdom, patience, and tolerance. I am convinced that we can and will use all of these. May I, therefore, cordially endorse the statement of the retiring President that the work of the Committee on Professional Education is of most immediate and pressing importance.

May I close with a personal word to the members of this Association who have honored me to serve as President

for the coming year. This responsibility is great—to the discharge of it, I shall give the full measure of my ability. I can find no words to express my gratitude equal to those of President Benjamin Lee in 1901 and echoed by Winslow in 1926:

"One who has devoted the best

years of his life to the study and practice of preventive medicine . . . may be pardoned if he expresses the sentiment that having received the verdict of his long valued friends and deeply respected peers, the summit of his ambition has been attained and earth has no richer prize to offer him."

A Veterinary Centenarian and Discoverer

DR. GRIFFITH EVANS, of Bangor, North Wales, attained his hundredth birthday, August 7. While in the army veterinary corps in India he discovered the trypanosome of surra, a disease of horses, camels and cattle. In 1885 this protozoön was named *Trypanosoma Evansi*. He thus laid the foundation of protozoön pathology, in which the next discoverer was Bruce, who in 1894 found that tsetse fly disease of animals was due to another trypanosome. (*Trypanosoma Brucei*). In 1903 he and Nabarro found that the tsetse fly also was the carrier of trypanosomiasis. In a letter to the *Times*, Dr. Ivor J. Davies of Cardiff recalls a visit of Osler to that town. He asked, "Where does Griffith Evans live?" A reply not having been forthcoming, he said: "What! Don't you know the

man who first saw a pathogenic trypanosome?" On his birthday Dr. Evans received in his bedroom a telegram of congratulation from the king and queen at the moment when Sir Frederick Hobday, principal of the Royal Veterinary College, presented a scroll stating that it is proposed to set up in the college a plaque recording the fact that Dr. Evans, the father of the veterinary profession, consented to lead the endowment movement.

Dr. Evans replied from his bed, to which he is confined by an accident, in a voice that could be heard outside the house. He discoursed for half an hour on scientific problems and mentioned that in his college days no microscopes were provided for students.—London Letter, *J.A.M.A.*, Sept. 14, 1935, p. 893.

Fifteen Years of the Committee on Administrative Practice^{*}

I. The Initial Steps

LOUIS I. DUBLIN, PH.D., F.A.P.H.A. (*Life Member*)

*Third Vice-President and Statistician Metropolitan Life Insurance Company,
New York, N. Y.*

IT is my pleasant duty to recall the initial steps which led to the organization of the Committee on Administrative Practice. I shall then turn the discussion over to Professor Winslow, who has been its guide and leader from the very beginning. He will tell you of the many activities developed by the committee. Finally, Dr. Rice, the Commissioner of Health of New York City, will attempt to evaluate some of the more important of these efforts to show in what ways they have served the public health movement during the last 15 years.

The earliest public health activities in America were extremely limited in scope. Up to the last decade of the 19th century, they consisted, for the most part, in the abatement of nuisances and the quarantine of epidemic diseases. A few weak attempts were made here and there to meet specific health problems, but very little was accomplished. In the 90's, Dr. Hermann M. Biggs of New York brought the bacteriological laboratory into the picture and largely as a result, the scope of the health movement broadened by leaps and bounds. The attempt to

control tuberculosis, the infectious diseases of children, and the venereal diseases were the immediate fruits. Later, the promotion of child hygiene and the educational work of the public health nurse extended the old-fashioned health department into an active and obviously useful agency.

By 1920, it seemed fairly desirable to take account of stock and, perhaps even more important, to consolidate the gains that had been achieved. On every hand, enthusiasts in the special fields of health promotion were urging the importance of their particular part of the program. In each city, certain of these special fields had been developed, some of them to a high degree, while other possible activities were wholly or almost wholly neglected. The conscientious health officer was calling for guidance. What should he undertake and to what extent? How could the usually limited funds at his disposal be most advantageously used? These were some of the questions which health officers were asking themselves everywhere.

Dr. Chapin of Providence had crystallized this point of view and questioned various activities which were passing for approved service in those days. He queried, especially, those practices which concerned the abate-

^{*} Read at a Special Session of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

ment of nuisances and a number of others which he thought were hardly within the scope of the public health officer. In 1915, in his study of state health departments, he showed for the first time how a quantitative evaluation of health service could be made. Dr. Chapin's work and the discussions that followed left a very definite impression that this was a good time to bring together the facts with regard to the current practices in American municipal health departments. It was accordingly, in 1920, that the Committee on Municipal Health Department Practice was appointed by the American Public Health Association to conduct such studies in the field of municipal service, very much as Dr. Chapin had shown in connection with the state work.

As far back as 1916, we, in the Metropolitan Life Insurance Company, had become greatly interested in the character of the organization of municipal health departments. The company, through its Welfare Division, under Dr. Frankel, had committed itself to a program of coöperation with health departments all over the country. The company had organized an extensive nursing service for the care of its millions of sick policy holders; it offered health officers large quantities of health literature for distribution and, perhaps most important, it agreed to employ its agency force and its other instrumentalities to arouse the interest of the policy holders in plans which the local health officer might have to extend his service. Under these circumstances, it seemed to us very desirable to get a glimpse of the status of health work the country over. Some cities were obviously further advanced than others and there was a great variety of procedures. Could the general level of health work be raised by making available to all health officers the facts with regard to the

most approved practices as demonstrated in the leading communities?

In February, 1916, a circular letter was sent out to the Metropolitan managers in the various parts of the country urging them to associate themselves with the plans of health officers and to find out for themselves the essential facts with regard to the work which was going on in their health departments. A brief blank was supplied for the record of their observations. A large volume of material came in indicating a great variety of conditions and of organization. In 1919, a more detailed and definite questionnaire was sent out in the hope that more useful information concerning local public health work could be obtained. As this inquiry progressed, it was discovered that some of the information would have to be supplied by the health officers themselves. After some experimentation, it was evident that we must give up the idea of relying on our managers to obtain this information, and the attention and coöperation of the health officers themselves must be secured. In April, 1920, a schedule was prepared which it was planned to send to the health officers of the 250 largest American cities asking them to supply the basic facts with regard to the organization and services rendered by their departments. They were also asked to state their more urgent needs and their plans for future expansion and particularly what the company could do to aid them in their local efforts. Before this questionnaire was actually distributed, it seemed desirable to try it out on a few of the more critical sanitarians of the country such as, Professor C.-E. A. Winslow, Dr. Charles V. Chapin, Dr. Donald B. Armstrong, Dr. Allan McLaughlin and others.

On May 17, 1920, I sent to Dr. Lee K. Frankel a report on the conferences with the sanitarians to whom the ques-

tionnaire had been sent. They were unanimous that the proposed investigation was timely and that there were great possibilities in the program, if properly conducted. There was considerable doubt, however, as to the ability of the company to gather the information directly by the questionnaire method. Professor Winslow was especially skeptical. In order to make the answers worth while, the questions had to be specific and technical in character. Because of the wide scope of the inquiry, the questionnaire must be lengthy and would involve a great deal of labor on the part of the health officers. There was virtual agreement among the conferees that the best method would be to have the actual inquiry conducted by trained persons working under the auspices of the American Public Health Association and with the approval of the state boards of health. Local health officers would coöperate with a representative of the state department where they might refuse information to the Metropolitan. It was, therefore, suggested that the company ask the Section on Public Health Administration of the American Public Health Association to appoint a special committee to take charge of the work, and especially to make the necessary contacts with the state and local health officers. The funds required for the actual canvassing were to be supplied by the company. Professor Winslow suggested that \$5,000 would see the work through, and this amount was appropriated.

In this way was initiated the work of the Committee on Administrative Practice. It was very clear from the outset that the committee must have Professor Winslow as its chairman. He very graciously accepted that responsibility. As you all know, he has for 15 years, except during his term as president when Haven Emerson served

as chairman, carried this burden with tremendous enthusiasm, initiative, and wisdom. He was associated at first with Dr. Charles V. Chapin, Dr. Wade H. Frost, and myself acting as Secretary. In the next few months, the committee was enlarged to include Dr. Donald B. Armstrong, Dr. Haven Emerson, Dr. Allan W. Freeman, and Dr. Lewis R. Thompson of the U. S. Public Health Service. Later, as the committee formulated its plans and began to function, its membership was extended to include a number of active health officers. To make sure that our plans were in keeping with the practical needs of the men on the firing line, many conferences were held with health officers all over the country and their active coöperation sought.

Never was a more congenial group of men gathered to carry on a task and never did they work more actively and intelligently to further their objective. The questionnaire was quickly beaten into shape. Space does not permit me to present this historic record form but I am filing it in the archives of the Association where it may later be examined by interested students. It consisted of 24 pages, each 12" x 18", and covered what we then believed to be the main points in the organization of municipal health departments. The problem of gathering the information from the large cities of the country was not easy to solve. It was essential that the information should in all cases be obtained through the visit of a personal representative of the committee to each city. Otherwise, many of the questions would have remained unanswered; others would have been misunderstood and the results from the various cities would have been vitiated through the lack of comparability or reliability. It was, therefore, decided that the surveys should be conducted by a small number of investigators acting for the committee, each using

the schedule in the same way and following certain rules and interpretations of the items as agreed upon. Each member of the committee undertook to be responsible for a group of cities in his immediate vicinity. We were extremely fortunate in obtaining the active coöperation of Surgeon-General Hugh S. Cumming of the U. S. Public Health Service, who generously assigned Dr. Lewis R. Thompson to the committee for a period of 10 weeks. Dr. Thompson surveyed 16 cities. In addition, the Surgeon-General directed 5 members of his staff located in various parts of the country to coöperate with the committee in completing the surveys of 9 cities in their immediate vicinities. The American Red Cross helped us by placing Homer N. Calver at the committee's disposal for the survey of 5 cities. I well remember canvassing the situation personally in the 8 cities on the Pacific Coast. Mr. Tolman, the Secretary, covered cities in the northeastern part of the country. Altogether, we received returns for 83 cities with populations over 100,000. This material became the source for a wealth of publications which soon began to appear under the imprint of the committee.

The tabulation of the material was an extensive task and W. T. Fales, then a student under Professor Wade H. Frost at Johns Hopkins, and Professor Ira V. Hiscock, associated with Professor C.-E. A. Winslow, were extremely helpful in tabulating the data and in digesting the material. At the Annual Meeting of the Association in New York City in November, 1921, the committee presented its first report, being a summary of its findings under 18 different main divisions. It appeared in the January, 1922, number of the *American Journal of Public Health*, and will always remain a landmark in the history of the Committee on Administrative Practice. It was

this material which later, much elaborated, resulted in *Bulletin No. 136*, published by the U. S. Public Health Service and entitled "Report of the Committee on Municipal Health Department Practices of the American Public Health Association."

This *Bulletin*, published in 1923, contained 468 pages and was divided in three main sections. The first prepared under the editorial supervision of Dr. Allen W. Freeman of Johns Hopkins, consisted of 18 chapters, each one on a special aspect of health department organization. The several chapters were prepared by members of the committee and their associates. Dr. Freeman wrote the important chapters on The Health Board and the Health Officer, Control of Communicable Diseases, Water Supplies, and Sewage and Sewage Disposal. Professor Hiscock summarized the findings on Infant Hygiene, School Health Supervision, Public Health Laboratories, Milk Inspections, Food and Drug Inspections, and Sanitary Inspection and Sanitation. Professor Winslow reported on Tuberculosis, and Public Health Nursing. Mr. Fales analyzed the Expenditures of Health Departments, and Mary Augusta Clark of the American Social Hygiene Association obliged with a chapter on Venereal Disease Control. Finally, I had the pleasure of contributing a summary of the procedures in Vital Statistics, and a member of my staff, Miss George Anundsen prepared a chapter on Public Health Education.

The second section was prepared by Professor Winslow and Dr. H. I. Harris who outlined An Ideal Health Department for a City of 100,000 Population. This ideal organization purported to "represent the best practice of the day in each of the various lines of health department work as observed in some one or more of the cities studied." It was in no sense a

visionary project, but was based entirely on the standards employed by the leading cities in each particular phase of health work. No form of procedure was suggested which had not proved practicable in some city under actual working conditions. This hypothetical health department, therefore, furnished an excellent measuring rod for the third section in which Dr. Emerson did an especially interesting piece of work in analyzing the individual practices of each one of the 83 cities studied.

The work of the committee was now fairly launched. It had proceeded far enough to clarify its program by announcing in 1924 the following three specific objectives: (1) the study of public health procedure; (2) the standardization of public health procedure, and (3) the presentation of the studies and standards to those members of the Association who may find them useful. I shall leave it to Professor Winslow to develop the work for the committee from this point. I desire only to say that what followed has become indelibly associated with the history of the Association during the last 11 or 12 years and with the extraordinary progress that has taken place in public health activity in the United States during this interim.

There are, however, one or two minor phases of the work of the committee which I think it is proper that I should consider briefly. The first refers to the personalities who have been associated with the committee during its history. We were extremely fortunate in bringing together a group of men who were congenial to one another and who were ready to give of their very best, irrespective of the time and effort which were called for. I need not sing the praises of Professor Winslow. His service on the committee speaks for him. It is a pleasure to record the extremely useful work of

Dr. Charles V. Chapin during those early formative years. His knowledge of health practices, his point of view, his critical acumen in revising the schedules, guided us away from a great many errors. Dr. Allen W. Freeman was a mountain of strength. He made the first major publication possible. Dr. Haven Emerson was always ready to help with his fertile imagination outlining new activities and new ways of making the work of the committee practically useful. It is impossible, of course, to list all of those who were associated with us in the initial group. I refer to these members because they have continued to serve the committee from the very beginning. I hope the other members who have worked equally hard will not take it amiss if I do not refer to their special labors, except that I must single out the contribution of Dr. George W. Palmer, who was largely responsible for the present form of the city appraisal form. In all, there have been 36 members of the committee since its beginning. Ten of them have served at least 10 years. Seventeen have served 5 or more years. Nine of our committee members have served as President of the Association and one of them is now President.

We were also extremely fortunate in our choice of Field Secretary or Executive Officer. The first of these was Mayo Tolman, a breezy picturesque character, who first set the work of the committee in motion. He had been a student of Sedgwick's and was a veritable dynamo of energy. He did an excellent job in drawing up the first schedule and in keeping hold of the many details of the first survey as it ran through the hands of many workers.

He was succeeded by a man of a very different type, no one less than ex-President Dr. Watson S. Rankin, of North Carolina. Dr. Rankin threw himself into this effort with enormous energy and with years of experience

behind him. For years he had been thinking of establishing norms by means of which we could measure the relative values of particular types of health work. His main contribution was the creation of the appraisal form which has had such a remarkable influence on the work of the committee. It was under his administration also that the schedule received a thorough revision, largely through the efforts of Dr. George W. Palmer, and became much more adapted to its purpose. Dr. Rankin's greatest contribution, however, was his ability to win the confidence of the health officers of the country and to obtain their acceptance of the committee's plan of evaluation and of standardization of practice, two factors very essential to the success of the future work of the committee. He resigned in 1925 to become Director of the Hospital and Orphan Section of the Duke Foundation, Charlotte, N. C.

He was succeeded by Dr. W. Frank Walker, who had gained wide experience through the survey of the American Child Health Association and in association with Dr. Henry F. Vaughan in Detroit. It will be quite impossible to credit Dr. Walker with all of the good works for which he was responsible. It was in his administration that the survey work of the committee was inaugurated. The time had arrived when individual cities wishing to go deeper into their health organization than the mere cataloguing of information turned to the Association and the committee for intensive surveys. Dr. Walker conducted these on a large scale and established an activity which has become an important one in the life of the Association. He also launched the City Health Conservation Contest. This was nothing short of a stroke of genius because it was through these contests that the possibilities of the schedule and the appraisal form

could best be realized. The competition set up through hundreds of cities joining together in the Contest has resulted in immeasurably raising the standards of public health work in the cities of the country. Later, the City Contest resulted in the organization of the Rural and County Contests, generously supported by the Kellogg Foundation. The Association is under tremendous debt to Dr. Walker for these many services. He resigned in 1931 to become Director of Public Health Studies of the Commonwealth Fund, and was succeeded by Dr. Carl E. Buck. It is hardly necessary for me to evaluate the services that have been and are being rendered by Dr. Buck and his staff. He is a worthy successor to the splendid men who have preceded him in this position.

Finally, it is my pleasure to refer briefly to the financing of the committee's work. It will be remembered that the first contribution was made by the Metropolitan in 1920. The company has continued to be interested in the work ever since. By 1927, we had succeeded in arousing the interest of other life insurance organizations which in more recent years have helped to finance the Health Conservation Contests. In 1925, the Milbank Memorial Fund contributed \$10,000 and in 5 years made available a total of \$40,000. The Commonwealth Fund made its first contribution toward the work of the committee in 1928 and has since then been a continuous and generous contributor, its total financial help amounting to \$135,600. Most of this large contribution was expended in conducting the work of the Subcommittee on Evaluation of Administrative Practices. Altogether more than half a million dollars has been expended by the committee during the 15 years of its history. Not a small part (\$128,000) of this total has been actually earned in services rendered by

the committee and its members in making surveys, and through consultation service in carrying the point of view of the committee into practical effect in individual states and cities. Altogether, there is in the financial history of the committee an excellent example of what can be done when a good idea works through channels of practical and trained men. I have no doubt at all that for every dollar spent by the committee, a great many more dollars have been loosened from municipal and state sources to improve public health work in the United States

not only temporarily but permanently.

In closing, it has been one of the great satisfactions of my life to have been instrumental in the organization of the committee, in helping to make possible its financial support, and in playing some part in the development of its program. The work began innocently enough through an interest arising in my office. The developments which followed have helped to make my work—and I am confident the work of hundreds of others—in the field of public health more significant and valuable.

The Hall of Fame, New York University

EARLY in November, the 1935 voting took place by which selections were made to fill additional niches in the Hall of Fame at New York University. There are spaces for 150 busts and of these 69 are now filled. The new election included William Penn, Simon Newcomb, and Grover Cleveland.

Most interesting to health workers is the fact that the highest name on the list of those who fell short of the necessary three-fifths vote of the 101 electors was none other than our own Dr. Walter Reed, the conqueror of yellow fever. He received

57 votes—61 would have elected him.

The history of these elections shows that most of the names have appeared in several lists before they were finally elected and it would seem quite probable that Dr. Reed may be elected at some time in the not far distant future. Of the 72 names already on the list, it is said that 13 are statesmen, 16 are authors, 5 are teachers and theologians, and 5 are educators. Seven are women. Most of the other names are men of letters. Nominees are not eligible for consideration until they have been dead for 25 years.

Fifteen Years of the Committee on Administrative Practice*

II. The Evolution of the Program

C.-E. A. WINSLOW, DR.P.H., F.A.P.H.A. (*Life Member*)
Professor of Public Health, Yale School of Medicine, Yale University,
New Haven, Conn.

THE Preacher long ago warned the people of Israel that "there is no new thing under the sun"; and the attempt to standardize health practice is no exception to the rule.

Haven Emerson, in his Sedgwick Memorial Lecture on Public Health Diagnosis traces the germ of the idea back to the *Doomsday Book* of William the Conqueror in 1086. Edwin Chadwick's report on *Sanitary Condition of the Labouring Population of Great Britain* (1842), Lemuel Shattuck's *Report of the Sanitary Commission of Massachusetts* (1850), and the report of the Citizens' Association of New York, *Sanitary Condition of the City* (1865) were more directly in our line of descent.

These early surveys were, however, primarily concerned with the sanitation of the physical environment rather than with administrative health practice. For the first real attempt to make a comprehensive evaluation of all the health aspects of community life in definite and detailed form, we must turn to the records of our own organization. At the Philadelphia meeting of the American Public Health Association

in 1874, a committee of 24 was appointed "to prepare schedules for the purpose of collecting information with regard to the present condition of public hygiene in the principal towns and cities of the United States, and the laws and regulations, state and municipal, relating to the same."

I have a photostat copy of the survey schedule prepared by John S. Billings (President of the Association in 1880) for this committee,¹ and it is one of the most interesting documents in the history of public health. It contains 411 specific questions under the following 20 headings: Location, Population and Climate; Topography and Geology; Water Supply; Drainage and Sewerage; Streets and Public Grounds; Habitations; Gas and Lighting; Garbage and Excreta; Markets; Slaughter Houses and Abattoirs; Manufactories (and Trades); Public School Buildings; Hospitals and Public Charities; Police and Prisons; Fire Establishments, Alarms, Engines, etc.; Cemeteries and Burials; Public Health Laws, Regulations, Officials-Municipal; Registration and Statistics of Diseases; Quarantine.

The schedule for Hospitals and Public Charities is a forerunner of the studies carried on so effectively by the American Hospital Association; and

* Read at a Special Session of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

the last three of the schedules listed above are precisely in the line of the work of the Committee on Administrative Practice. They cover the constitution, personnel, salaries and powers of boards of health, number and qualifications of staff, quarantine practice, annual reports, registration of vital statistics, mortality from important diseases and at important age periods.

This was truly an amazing document. It was, however, too far ahead of the times for widespread application. Forty years must pass before this germinal concept came to actual fruition, under the influence of another great pioneer, Charles V. Chapin of Providence. In one after another of his addresses he emphasized the need for quantitative evaluation of health practices.² In 1915 he showed for the first time in his study of state health departments how such an evaluation could be made.³ Five years later, in 1920, the Committee on Municipal Health Department Practice was appointed by the American Public Health Association as a result of those conversations between members of the Association and officials of the Metropolitan Life Insurance Company which Dr. Dublin has described.

The general objectives of the committee were stated as follows in its first annual report (1921).⁴

The need of authentic information on the practice of municipal health departments of American cities has long been recognized by all engaged in public health work. It is generally known that a great variety of procedures are in effect; that the organization of the health departments differs in different communities; that the amounts spent per capita for any branch of health service vary considerably and that, in other respects, few standards are available to health officers who would pattern their departments after those which predominate in American practice or achieve most satisfactory results. It was thought that the collection of data as to the current practice of large municipal health departments would repay the effort and that

perhaps, out of such an investigation it would be possible to discover the best procedures and to forward the movement for the simplification and standardization of health department practice in our cities.

A year later, in the fall of 1922 the A.P.H.A. at its Cleveland meeting adopted the report of its Committee on Reorganization which emphasized this problem as a primary function of the Association itself in the following paragraphs:

The objectives of the Association should be the preparation, study, standardization, and presentation of scientific public health procedures, the best method by which such knowledge can be given to the public, and the expression to the public of professional opinion in regard to such procedures.

Later on under Section C, *Information File*, the report recommends

... that there be maintained at the central office of the Association such records as are obtainable and can be kept current with regard to the organization, expenses, procedures and results of public health practice in organized health departments in countries represented in our membership.

In 1923 the committee through the assistance of the U. S. Public Health Service, completed—as Dr. Dublin has described—its first important study, a survey of health practice in the 83 largest cities of the United States. In this year, too, Dr. W. S. Rankin obtained leave of absence from the State of North Carolina to serve as its first full-time Field Secretary.

By 1924, the committee had proceeded far enough with its work to clarify its program by announcing the following three specific objectives:

1. The study of public health procedure
2. The standardization of public health procedure
3. The presentation of the studies and standards to those members of the Association who may find them useful.

In 1923 and 1924, the committee attacked its second major objective, the preparation of an appraisal form for

the measurement of actual administrative achievement by a quantitative objective scoring procedure—again following the lead provided by Dr. Chapin in 1915.

Early in its career (1923) the committee had suggested that its studies should be extended to Canada, Cuba, and Mexico and to states, counties, and small municipalities as well as to large cities. In 1925 its name was changed from Committee on Municipal Health Department Practice to Committee on Administrative Practice in order to indicate its potential wider scope. The Milbank Memorial Fund made its first grant to the committee in this year; the first city *Appraisal Form* was completed; and Dr. W. F. Walker succeeded Dr. Rankin as Field Director.

For the year 1926, Dr. Haven Emerson served as Chairman of the committee and its first active subcommittees were organized, dealing with County Health Practice, Administrative Record Forms, and Analysis of Health Department Functions and Results. In the fall of this year, at the Buffalo meeting, the committee was reorganized and placed on a permanent basis with a membership of 16 made up as follows: 12 members at large, appointed for 4 year terms, the terms of 3 members expiring each year; the 3 officers of the Health Officers Section (later changed to 3 representatives appointed by that Section); and the Executive Secretary of the Association. This change essentially involved the recognition of the committee as the "technical service division" of the Association.

In 1927 the committee published *Community Health Organization*, under the editorship of Professor I. V. Hiscock, which was its first comprehensive effort to present the results of its studies in the form of a complete program of standard community health

service. In 1928 the Commonwealth Fund joined the list of our generous supporters by making a grant for studies of 3 state health departments and of rural county services.

In 1929, was held the first Health Conservation Contest, sponsored by the U. S. Chamber of Commerce and actually conducted under the technical guidance of the committee, with funds provided by a group of life insurance companies. This step (although foreshadowed by certain earlier efforts of the committee) marked its first comprehensive effort along a new line. Nearly 10 years had been spent in collecting data, in formulating standards, and devising methods of appraisal. The time was at last ripe for using these technics in an organized effort to raise the general level of health practice throughout the country.

In 1930, the committee undertook still another task, the evaluation of individual health procedures with a view to improving the details of health practice. At first we could only establish standards on the basis of group judgment, and for some time to come most of our practice must rest upon this basis. Slowly but surely, however, we hope to remould group judgment by the test of accurate scientific analysis of methods and results.

In 1931, Dr. Carl E. Buck replaced Dr. Walker as Field Director. In 1933 our first comprehensive survey of rural health service was issued under the editorship of Dr. A. W. Freeman; and in 1934, the Health Conservation Contest idea was applied to county health departments under a grant from the W. K. Kellogg Foundation.

Such have been the high points in the chronological history of the Committee on Administrative Practice. It may be noted that its activities group themselves in logical order under 5 main heads: (1) collection of data as to actual administrative practice, (2)

formulation of a typical or normal program of adequate community health service based on those data, (3) the preparation of an appraisal form by which actual health services in a given community may be objectively measured, (4) the making available of the knowledge and experience of the committee to health officers in such a way as to promote sound local programs and, finally, (5) the securing of public backing for such programs, by using the standards and the comparative ratings at our disposal to stimulate emulation as between various local areas.

First of all, it was necessary to obtain a clear idea as to the actual practice of American communities in the field of health organization. Such a picture, as it related to state health departments, Dr. Chapin had given us in 1915. Dr. Dublin has shown how—with funds provided by the Metropolitan Life Insurance Company and with the generous coöperation of the U. S. Public Health Service—we prepared and published our first comprehensive survey of municipal health practice.⁵ This has been so fruitful in its results that it is now a little difficult to visualize the obscurity in which we labored before information of this kind was available. The younger health officers can scarcely imagine what it meant to develop a health program with no knowledge whatever of practice elsewhere—except such as we might pick up in conversation at meetings and by visiting or corresponding with neighboring departments.

Bulletin 136 proved so valuable that the American Child Health Association almost at once began a similar study of services in 86 smaller cities (40,000 to 70,000) which was published in 1925.⁶ Our own committee, again in coöperation with the U. S. Public Health Service, resurveyed the 83 cities studied in 1920 as of the year

1923 and extended the limits of population down to the 70,000 figure which was the upper limit of the A.C.H.A. study. This second survey of 100 large cities was published as *Bulletin 164* of the Public Health Service in 1926.⁷ Thus 10 years ago, we had already gained a reasonably clear picture of actual administrative practice in the 186 cities of the United States which had populations of over 30,000 in 1920.

In 1927, the International Health Division of the Rockefeller Foundation resurveyed the state health departments for the Conference on State and Provincial Health Authorities⁸ and finally 2 years ago, our own committee presented (under the editorship of Dr. Allen W. Freeman and with Dr. Crittenden as principal field surveyor) the results of a comprehensive survey of rural service.⁹ This investigation (generously financed by the Commonwealth Fund) was made under the direction of a sub-committee headed by Dr. E. L. Bishop and involved two separate lines of approach. Carefully prepared questionnaires covering the major items of information desired were sent out to all full-time county health departments and returns were actually received and tabulated for 337 such counties. This general information was supplemented by an intensive survey of 46 counties in 28 states and 2 Canadian provinces. These counties were selected to represent various geographical areas of varying economic status and to include both organized counties (27) with full-time health officers, and unorganized counties (19) representative of the four-fifths of our rural counties without full-time health service. By combining the information obtained in these two fashions a remarkably clear picture (and a very challenging one) was obtained of the achievements made, and of the disheartening gaps which still

remain unfilled. This report was another pioneer accomplishment of major import to the cause of public health—comparable only with the first city survey begun in 1920.

The Committee on Administrative Practice feels that the time is more than ripe for a second re-survey of state health departments, and hopes to be able soon to undertake that task if the Conference of State and Provincial Health Authorities should desire it. At some future date, a re-survey of rural health service will no doubt be desirable. In the municipal field, however, it seems probable that the stage of comprehensive and nation-wide surveys may perhaps have passed, at least as far as purely quantitative studies are concerned.

What is needed now in the municipal health field is (1) up-to-date information as to current changes, in the form of general trends such as those concerning budget allotments and personnel; (2) continuing review of new administrative procedures in special fields; and, particularly, extensive as well as intensive studies of particular procedures with a critical analysis of costs and of results actually attained. The first sort of information can be obtained by the questionnaire method, the second by visits to particular cities where special advances have been made.

In its 1923 report, the Committee on Administrative Practice recognized the need for "a central clearing house for current information in regard to health department practice." It seemed to the committee that "the natural and logical first step was to provide for the keeping up-to-date of the information already secured at considerable cost in regard to the large cities of the United States." The U. S. Public Health Service was, in our judgment "the logical body to lead in this work in view of its general program and policies and in view of the service which it has

rendered to so many individual communities in the line of counsel as to administrative health procedure." The matter was therefore presented to Surgeon-General Hugh S. Cumming and, to our great gratification, he agreed to establish within the U. S. Public Health Service an office of Administrative Health Practice, under the direction of Dr. Paul Preble.

The office of Administrative Health Practice has proved of the greatest value but during the past few years the need has become increasingly apparent for somewhat more intensive efforts than have heretofore been possible along the lines of continuing analyses of current progress. The information available to us in the returns made by cities competing in the Health Conservation Contest seemed of potential value in this connection. In 1932, therefore, the C.A.P. created a new sub-committee on Current Health Department Practices under the chairmanship of Dr. J. W. Mountin. Dr. Mountin had succeeded Dr. Preble as chief of the Division of Administrative Practice of the U. S. Public Health Service. Recent analyses made by this committee of health department budgets and personnel in the depression have been published in the *American Journal of Public Health* during the current year and furnish powerful arguments for checking and compensating for the serious inroads which have been made upon the health defenses of the nation.

The second task of the committee was to utilize the material assembled through our surveys in the form of a typical community health program which might be set up as a norm or as a general guide to be used by any community which aspired to provide really adequate health protection for its citizens. It required some courage in 1920 to attempt such a task and I well remember the trepidation with

which we approached it. In our first important contribution, however, the 1923 report (*Public Health Bulletin 136*) we included a chapter on *An Ideal Health Department for a City of 100,000 Population*, prepared by Dr. H. I. Harris and the writer.¹⁰ This was, so far as I am aware, the first attempt ever made to formulate a standard community program. As our studies advanced, it seemed desirable to expand this program and to modify it in the light of the new information at our disposal, and Professor Ira V. Hiscock was asked to prepare a new draft of the standard program. This was issued in 1927.¹¹ In 1932 a second revision of this report on *Community Health Organization* was published, again under the editorship of Professor Hiscock.¹² Its sound analysis of administrative policy and the philosophy of broad social relationships involved make this, in my judgment, a document of the very first importance.

The somewhat adventurous policy involved in the attempt to formulate in detail an adequate well balanced community health program has been more than justified by experience. It has been astonishing even to those of us who have been most hopeful to see how completely the scheme of ideal community health organization has actually fitted the facts. It is no static program, for new opportunities for productive health service are continually opening before us; and successive editions of the outline must continue to reflect such advances. At a given moment, however, the actual practice of the most advanced cities corresponds in striking degree to the standard program; and when we began to apply it to the handful of rural areas with really adequate health service the correspondence proved equally close. One of the most valuable features of *Community Health Organization* lies in its

estimates of the personnel and budget necessary for satisfactory service. Here, too, experience shows close conformity between theoretical computation and actual results. Again and again, we have found in comparing a given city with the general scheme that precisely those activities which had less than the estimated budget allotment were the activities which in practice fell short of reasonable attainment. It is, in large part, thanks to this document that we can stand with complete confidence on the requirement of \$2 per capita (from official and voluntary agencies combined) as essential for the support of an adequate community health program—in rural as well as urban areas.

A second phase of this general problem of developing sound health practice has been concerned with the working out of standards for certain details of health department procedure, as distinguished from the broad general program as a whole. This function has been largely performed by a remarkably active and devoted series of sub-committees which include many coöpted members from outside the C.A.P. itself. The first of these sub-committees were organized in 1926. They include at present the following fields of work: Record Forms, for many years under the chairmanship of Dr. George C. Ruhland, recently succeeded by Dr. George T. Palmer; Organized Care of the Sick, under the chairmanship of Dr. Michael M. Davis; Manual of Public Health Administration, under the chairmanship of Dr. Henry F. Vaughan; Annual City Health Department Reports, originally headed by Dr. C. H. Jones, now under the chairmanship of Dr. John L. Rice; Public Health Nursing under the chairmanship of Sophie C. Nelson; and Relationship of Social Workers to Public Health, under the chairmanship of Dr. W. Frank Walker. All of these committees have been

active and have published reports at varying intervals. The achievements of the sub-committee on Record Forms have been, perhaps, particularly notable and have recently borne fruit in a Manual on Record Forms which has just been completed and is ready for publication.

For the most part, our standard procedures have rested on the empirical basis of practice, as exemplified in the actual work of health departments. We have long felt, however, that our ultimate goal must be to substitute for empirical group judgment more exact knowledge based on the statistical analysis of results actually achieved. To this end we organized in 1930 a new sub-committee on Evaluation of Administrative Practices under the chairmanship of Dr. Haven Emerson, and with financial support from the Commonwealth Fund. The aim of this committee is to take up one by one certain definite and specific procedures, to analyze them in detail and to measure the results in preventing morbidity and mortality actually attained by particular methods of administrative control. The task is an extremely difficult one and progress is necessarily very slow. Already, however, four contributions of substantial importance have been made in this field. They have dealt, respectively, with the comparative merits of various procedures for active immunization against diphtheria (Dr. William H. Park); with isolation procedures for the control of scarlet fever (Dr. John E. Gordon); with the effect of immunization of certain specific age groups in the control of diphtheria (Dr. Edward S. Godfrey); and with the effect of varying types and amounts of prenatal care upon maternal and infant mortality (Drs. M. Tyler, Harold H. Walker and John H. Watkins).

Additional studies are now under way with regard to methods used in the

control of infant mortality and to isolation procedures for the control of measles and whooping cough. We believe that, in spite of their inherent difficulty, studies of this kind furnish the only assurance of developing our public health practice on a really sound and scientific basis. We hope and trust that resources may be found for continuing such investigations in the future.

The third major task of the committee was to devise a method by which the health officer could appraise the results actually attained by his own program and determine how far it corresponded to the best current practice and how far—and in what particular respects—it fell short of such practice. If the preparation of a normative community health program called for a certain temerity, the attempt to formulate a definite scheme of appraisal was even more hazardous. Could any plan be devised that would be reasonably applicable to various communities with their widely differing problems? Would not the attempt to formulate a score card or measuring rod for so complex a thing as a community health program lead to a sterile mechanism unrelated to reality? Would not any possible scheme work hardship on certain health departments and lead to unmerited criticism? If it did gain acceptance, would it not tend to standardize an incomplete program and prevent progress? I can scarcely make my hearers realize how grave these objections seemed to us; but I can perhaps illustrate our state of mind by recalling that one of the most valued members of the committee resigned rather than participate in so unscientific a procedure.

Nevertheless, the committee as a whole felt that the possible results were worth all the risks; and we decided to go ahead. In April, 1923, Dr. Chapin prepared the first draft of

an appraisal form "to provide in the first place for an evaluation of the relative importance of various lines of public health activity, and in the second place for an estimate of the service actually rendered along each line of activity." During the next year, 1924, Dr. Rankin, as Field Secretary of the committee, devoted a large share of his time to the problem. Fortunately, the American Child Health Association, as a result of its study of the 86 smaller cities had realized the same need for an appraisal form. The two organizations recognized the importance of coöperation and, in a conference lasting about a week, the two independent forms were consolidated into one. The plan was presented for counsel and advice to the New England Health Institute and to groups of health officers in Ohio and Michigan. The various national health organizations were consulted with regard to the respective sections in which they were particularly interested. In August, representatives of the New England, Ohio, and Michigan health officers spent 4 days in revising the document, and took it home for actual use in the field in order to test its possible value. In its report for 1924 our committee commented on the matter as follows:

We are convinced that an appraisal form, if it can be arrived at by the procedure here outlined, would prove of real value to the individual health officer in helping him to develop a balanced departmental program based upon relative values; to check up on the performance of his own bureaus and thus maintain the department at the highest point of efficiency; to defend himself when unjustly attacked, by showing that his department is organized in accord with the views of his professional colleagues; to secure funds for expansion by indicating where his organization falls short of that generally accepted as ideal; and to secure the coöperation of local voluntary health organizations along the most effective lines.

The possible advantages of the appraisal idea were forcibly presented as

follows in the report of the American Child Health Association on the use of its first tentative rating schedule in the 86 cities of between 40,000 and 70,000 population. This report says:

As a brief for annual appropriations of the Department of Health—In several cities the rating schedule has been used to show in a comparative objective manner certain deficiencies in the department of health, and the expenditures which would be required to secure a full credit in place of these deficiencies. When presented in this manner to the appropriating body of the city, as a part of the health officer's budgetary request, the health department was, in one instance, the only department of the city government to receive an increase (amounting to 14 per cent) for the coming year. In another instance in the face of a strong movement for retrenchment throughout the city government, the health budget, presented in the light of the rating schedule, was the only departmental budget to remain uncut.

As a basis for a Health Program—The value of the rating schedule as an outline of a well balanced health program has appealed to several health officers to such an extent that their future programs are definitely based upon achieving the standards set in the schedule. . . .

As a basis for an Annual Report—It has occurred to one health officer to incorporate in the annual report of his health department the detailed rating of his city, for the 83 items included in the schedule, and to publish the score attained, with full discussion of many of the items. Another health officer has largely improved the character of his annual report in the light of the *Appraisal Form*.

As a means of interesting a Mayor or Chamber of Commerce—In a city which had recently scored itself the health officer was studying the rating when the mayor of the city happened to enter the office of the health department. Upon being shown the low rating of the city in diphtheria prevention the mayor inquired what could be done to improve the situation. When the health officer explained that he could secure a full score (30 points) if he had \$175 with which to buy toxin-antitoxin, the mayor promised to make the sum available from special funds. Other health officers have taken the rating of their city to the mayor or the chamber of commerce and by comparing the local rating with that of other cities have awakened a new interest in the city's health record.

As a means of arousing and cementing the interests of the Departments of Health and Education and of the private agencies in each other—A striking outgrowth of the use of the rating schedule in one city where the findings were reported in a special meeting, was the development of a new sense of the interdependence of all health agencies on each other and the formation of a joint health committee on which all agencies were represented under the leadership of the health officer. In another instance the rating schedule brought to the health officer for the first time the realization that he should coöperate with the department of education in its health work if his city was to secure the fullest return from its health activities. School medical inspection was promptly started.

Such evidence as this greatly strengthened our conviction of the value of the plan; and after the elaborate sampling of group judgment described above, tentative drafts of the *Appraisal Form* were issued for further preliminary study in March and in August of 1925 (the latter being called the first edition). The form was finally revised, approved, and officially distributed in a second edition as of January, 1926.

Prepared in this way, with the co-operation of so large a group of health officers and of all the voluntary national health agencies, the *Appraisal Form*, from the first, met with a reception which belied our fears. To compare health department achievement in various communities on the basis of death rates was clearly unreasonable on account of inherent differences in local sanitary, social and economic problems. To compare appropriations and personnel alone was as obviously unfair, since available resources might be used with great or with little efficiency. Between resources on the one hand and mortality rates on the other we had chosen the measuring rod of actual services performed in the belief that "such activities, conscientiously performed over a reasonable period, inevitably lead to the ultimate end of all

public health work—the conservation of human life and well-being." The objective and generally quantitative measures of performance (now nearly 200 in number) were sufficiently numerous to be truly representative; and the standards adopted—based, in general, on the actual performance in each respect of the upper fourth of the cities for which data were available—were fair and reasonable.

To avoid the danger of over-standardization and calling a halt on progress, it was agreed that the *Appraisal Form* should be revised at intervals of 3 to 5 years; and in 1926 a sub-committee was appointed under the chairmanship of Dr. George T. Palmer to prepare a revised form. The third edition, on which this committee labored with tireless energy, was issued in January, 1929. Its most important change lay in the fact that instead of a total 1,000 point score for all activities the new form was based on a 100 point score for each major activity, with a conversion factor making it possible to compute a total score when desired. This change was significant of an altered emphasis. In 1924 we thought of relative values as our major problem; by 1929 we had come to realize that "an estimate of the service actually rendered along each line of activity" was the most important aim which could be realized by the use of the form.

Meanwhile, in 1927, a second sub-committee on Rural Health Work, under the chairmanship of Dr. E. L. Bishop, had prepared a tentative *Appraisal Form for Rural Health Service*, a second revised edition of which was issued in 1931. A little later, we extended the idea to the field of industrial hygiene and a sub-committee on Industrial Health Appraisal was appointed under the chairmanship of Dr. L. D. Bristol. This committee issued in 1933 a form for scoring industrial health

services which is now being tested out in actual practice. A fourth edition of the *Appraisal Form for City Health Work* was published in January, 1934, utilizing many new ideas developed in connection with the rural form.

On the whole, the success of the appraisal concept has exceeded our most optimistic expectations. So far as we are aware, the fear that low scores might be used as a basis for unfair criticism of health departments has proved to be unfounded; and the danger of undue complacency resulting from high scores has been avoided by periodic revision with rising standards of attainment. Many just criticisms have been made of individual items, but most of these can be met and are being met in successive editions, which are prepared in the light of actual use by the health officers of the country. The objection that our form measures quantity rather than quality of service is in part a valid and inescapable one; but experience has shown that a large proportion of the quantitative standards of appraisal actually depend for their attainment upon quality of service as well. Another real objection lies in the difficulty of giving weight to the preventive services performed by private physicians; but the form does provide for their inclusion wherever records of such services can be obtained. The *Appraisal Form* has fully justified itself by the test of application. In hundreds of careful surveys its indication of shortcomings in particular activities has been fully substantiated. The best health departments throughout the country use it as a routine measure of their own efficiency; and it has proved, as we believe, one of the most powerful forces ever brought to bear on the general improvement of public health practice.

Our fourth objective was to make the results of our surveys, our standards of administrative practice and our ap-

praisal procedures directly available to the health officers who must ultimately utilize them in actual practice. This has, in part, been accomplished by the simple publication of our surveys, of the various editions of *Community Health Organization* and the *Appraisal Forms*, and by the reports of our various sub-committees. Correspondence with individual health officers in regard to details of administrative practice has occupied a large part of the time of the committee staff; and in 1925 we began the regular issue of a *Health Officers News Letter* to disseminate current information of a more general nature.

A more direct and important type of service has been involved in the provision by our staff of individual local surveys and consultations to particular communities desiring such aid. In the report of the committee for the year 1923 this problem was discussed as follows:

In addition to the collection and dissemination of information in regard to current procedures it was felt that something more was necessary. As we understand the aims of the members of this association they desire a clear picture of present conditions chiefly in order that those conditions may be improved in the future. Public health practice is in a dynamic, not a static, condition. The object of the health official is to improve the machinery now at his disposal so as to raise it to the highest point of efficiency and to supplement that machinery by obtaining new appropriations sufficient to make his organization meet the requirements of the new public health. It has seemed to your committee that the most important service which the American Public Health Association could possibly render to its members would be to establish a direct field service for the assistance of the executive officers of health departments along the lines laid down above.

The assistance of the Metropolitan Life Insurance Company made it possible to begin a service of this kind in 1924.

The surveys made by the committee

have been essentially of two kinds. The comprehensive studies conducted on cities in 1921 and 1924 and on rural counties in 1932 were made chiefly for the purpose of accumulating data on which our standards of practice could be based; and of course from every survey our staff learns something which is applicable in other surveys. Aside from the three general studies mentioned above, however, the staff has in the last 15 years conducted surveys in 31 states, the District of Columbia, and the Islands of Hawaii. Sixty-five of these surveys have been made in 56 cities (9 being re-surveys), 36 in 24 counties (including 12 re-surveys) and 6 in 5 states (one re-survey). All of these surveys were primarily designed for the guidance of the communities in question rather than for the accumulation of information by the committee itself.

For the most part these local surveys have been paid for by the communities concerned; and this seems in general a sound procedure. Our present policy was announced in 1933 as follows:

The Committee on Administrative Practice of the American Public Health Association offers the following types of health service:

1. Complete or partial health surveys of states, counties, municipalities or organizations.

Such surveys involve a complete stock-taking of the health facilities of the organization or area under consideration; a careful analysis of services rendered in relation to existing problems and cost; and, finally, a report on findings and recommendations for future program.

2. Consultant service in relation to specific problems.

Such service would include, for example, advice and assistance concerning: the inauguration of a new division or activity such as child hygiene; record keeping; how to determine the degree of diphtheria protection among children of different age groups, etc.

3. Advice on readjusting health activities or programs to new conditions precipitated by the necessity for extraordinary economy.

All the above services are rendered at cost, on a *per diem* basis, except where a com-

munity or organization desires a definite contract, so that only such service as is actually rendered is paid for.

We have always felt, however, that the committee should have at its disposal resources which would make it possible under special conditions to make surveys urgently needed by particular communities where no local funds to pay for the study were at the moment available. We still hope that this ideal may ultimately be realized.

The fifth and last of our major objectives, the securing of popular support for public health programs by using the appraisal scheme to arouse local interest in health achievement, is somewhat distinct from the rest of the committee's work. It might quite logically have been undertaken by some other organ of the Association. The idea of developing a sound competitive spirit between various communities in the field of health administration was, however, as I recall, a dominant factor in the mind of Dr. Lee K. Frankel of the Metropolitan Life Insurance Company. When the first grants were made for the committee's work in the year 1923, we suggested that it might be helpful to award medals to certain cities of outstanding merit in community health service, as evidenced by their showing on a special scoring plan. This suggestion was criticised in a subsequent discussion at the Boston meeting and after obtaining by letter the reactions of the health officers of the 83 large cities the project was abandoned for the time being.

Three years later, however, in 1926, the idea was revived in a modest form and on a small scale by coöperation of the committee with the General Federation of Women's Clubs in an annual competition between towns, in which the local clubs prepared a brief summary of the health service of their community, and a free survey was provided by us for the town having the best

record. In the next year Dr. W. Frank Walker (who had been chiefly responsible for establishing contact with the Federation) interested the U. S. Chamber of Commerce in the promotion of health work through its bulletins and other publicity material.

Finally, by 1929, the time seemed ripe for a really comprehensive project. The appraisal form idea had gained general acceptance by this time and preliminary exploration of the general sentiment of health officers showed that the doubts experienced 6 years before had largely disappeared. Dr. Louis I. Dublin was successful in obtaining financial support from a group of life insurance companies, and the first Health Conservation Contest was actually undertaken. This contest, which has now become a regular annual event, is sponsored, both nationally and locally, by the Chamber of Commerce and financed by the coöperating insurance companies. The preparation of a brief appraisal form to be used in submitting returns, and the actual awards are handled by special committees appointed by the U. S. Chamber. The technical conduct of the work, with its extensive field service is, however, in the hands of the C.A.P. staff, and certificates are delivered to the health officers of the winning cities in the 6 population groups at the Annual Meeting of the American Public Health Association. In 1933, when the funds for the support of the contest were reduced, we were forced to call upon the state health departments for aid in the necessary consultation service; and the hearty and generous coöperation of the state health officers has been most gratifying.

The number of cities actually submitting schedules in the city contest rose from 108 in 1929, to 172 in 1931, and fell again to 97 in 1934.

Last year, through the generous support of the W. K. Kellogg Foundation,

it was possible to inaugurate a similar Health Conservation Contest for county units, parallel with the city conservation contest and carried on in essentially the same fashion under the auspices of the U. S. Chamber of Commerce.

As in the case of the committee's earlier pioneer ventures, so with the conservation contests, anticipated difficulties have been conspicuous by their absence. Only in the rarest instances have complications developed and, on the whole, the health officers have been enthusiastic over the contest and its results. It would be possible to recount scores of individual instances in which high attainment in the contest has been a major factor in maintaining appropriations and protecting personnel. I personally know that in two of the largest cities of the country a health officer whose tenure was seriously threatened received reappointment from a new administration almost wholly as a result of the concrete evidence of achievement furnished by the *Appraisal Form*. Many more cases could be cited in which low scores in the contest have been successfully used as arguments for increased appropriations at points where particular deficiencies had been revealed. It would be difficult, I think, to cite any single force that has done more to protect and promote high standards of health service than has the Health Conservation Contests.

In the first 15 years of life of the Committee on Administrative Practice it has thus been possible to attain in considerable degree all of our five major objectives.

The committee has developed a technic of health surveys and has so applied that technic as to present a reasonably clear picture of administrative health practice in the United States in both urban and rural areas.

It has crystallized the best elements of such practice in the form of a

Manual of Balanced and Adequate Community Health Organization which has proved of incalculable value in promoting progress along sound and fruitful lines; and has supplemented this general outline by the preparation of standard record forms and by intensive evaluation studies with regard to individual procedures.

It has prepared an *Appraisal Form* which is today generally accepted as a valid instrument for the objective and quantitative measurement of actual attainment in the field of administrative health practice and for the weighing of the relative degree to which various activities should be modified to build a balanced program.

It has rendered direct survey and consultation service to hundreds of cities, and serves at all times as a center for the interchange of information as to the most promising current trends in the field of administrative practice.

In coöperation with the U. S. Chamber of Commerce, it has made possible the carrying out of Health Conservation Contests in such a way as to promote sound competition between various communities and to stimulate those communities to a higher degree of moral and financial support for their local health programs.

These results have been made possible by a number of fortunate circumstances. We could have done nothing without the generous aid of the Metropolitan and the other insurance companies, the Commonwealth and the Milbank Funds and the W. K. Kellogg and other foundations which have supported our work. We have depended for wise guidance on the untiring service and the sound judgment of the committee membership; and I may say that in a somewhat wide experience of committee work I never knew a group with so harmonious a spirit and so universal a readiness to work as the

C.A.P. We have owed a very large part of the results achieved to our Field Directors, Dr. Rankin, Dr. Walker, and Dr. Buck, to Dr. Wallace and the other members of our field staff, to such active special collaborators as Professor Hiscock, and to our office secretaries, Mrs. Fraas and Miss Tonnele. Above all, however, the work of the committee has been made possible by the active participation of the members of the A.P.H.A. as a whole and particularly of the health officers—who took so large a share in the surveys, in the preparation of the *Appraisal Form*, and in the application of all the results of our studies. As a matter of fact, it is not the C.A.P. which has done these things. It is the health officers themselves who have accomplished results through the instrumentality of the committee as their central clearing house.

Herein lies the real significance of the entire chapter in the history of public health which we have here reviewed. A professional group of public functionaries has determined to pool the resources of its knowledge and experience in order to establish and maintain the highest possible standards of scientific attainment and of public service. During the brief period of 15 years they have worked out such standards and made them fruitful in actual achievement from one end of our country to the other. They have transformed administrative health practice from a medley of local and accidental enterprises to a concerted national program, growing and developing with the years, modified wherever desirable to meet local conditions, but everywhere based on sound basic principles and moving along considered and directed lines of progress. In so doing they have registered one of the major advances in the story of man's conquest of preventable disease; and they have set an example which may well have

its followers in other areas of the complex field of governmental service.

The X-ray Examination of Tinned Foods

THE consideration which has been given to the accepted methods of examination of tinned foods reveals that, short of the actual opening of a tin, extreme difficulty is associated with the giving of an accurate diagnosis as to the soundness of the content. Too often it would seem that stress is laid on methods which rely on the use of the human senses and consequently the findings may be very diversant according to the examiner's interpretation and the acuity of his sense organs. For instance, percussion, palpation, and shake tests might give very different results at the hands of a zealous inspector, or alternatively, at the hands of an importer. Disputes with consignees in the various ports I have been associated with led me to search for new methods which could be employed for the examination of this type of food.

One day while reading a technical article on the application of X-rays to industry, and especially in connection with examination of flaws in steel, it occurred to me that it might be possible to adopt X-rays to the examination of tinned food.

. . . Radiography has the following advantages:

1. A permanent record is available for inspection by anyone and may be of use in legal proceedings.
2. The tin is not opened and if deemed to be sound is available to the trade and its price saved.
3. An opinion may be vouched more quickly than in detailed internal inspection.
4. The personal error is more nearly eliminated than in the percussion, palpation, and shake tests.

Fifteen Years of the Committee on Administrative Practice^{*}

III. The Viewpoint of a Health Officer

JOHN L. RICE, M.D., F.A.P.H.A.
Commissioner of Health, New York, N. Y.

WE all realize the substantial progress that has been made in administrative public health during the past 15 years. Who or what has been responsible for this advance, in putting public health a little closer to the goal of greatest usefulness? Effective intelligent leadership has played the leading rôle. Has this leadership come from one or more health officers working in separate committees? Has it come from a physician or group of physicians who decided that public health must go forward? Has it come from unofficial health agencies leading the way? Has it come from the general public or from city governments' realization that public health is an investment rather than an expense? While some of these have taken a part, the real leadership has come from the Committee on Administrative Practice, a group of experienced, earnest public health workers who have pooled their broad knowledge and experience and have evolved most of the steps that have been effective in raising the level of public health administration throughout the country.

WHAT HAS THE COMMITTEE DONE FOR THE HEALTH OFFICER?

Since the organization of the Committee on Administrative Practice 15

years ago, it may be safely stated that *all* health officers have reaped substantial benefits from its activities. I refer particularly to the service it has rendered by: (1) providing the health officer with standards of performance for various public health activities by which he is able to analyze his program objectively; (2) setting up a well balanced plan for a public health program; (3) suggesting standard forms for recording information on essential health services; (4) making available expert personnel for consultation and advice on special problems, as well as for complete surveys; and (5) stimulating and encouraging improvements in community health programs through the annual Health Conservation Contests.

Standards of Performance—The history of the development of standards for evaluating public health work, and the pressing need for such standards, are so well known that it is unnecessary to repeat the story here. Nor is it necessary at this time to dwell upon the differences in viewpoint regarding the real value of the *Appraisal Form*. It is important, however, to point to a few significant results which have followed the development and intelligent application of these standards.

We are all familiar with the expansion of health department activities from the basic sanitary and communicable disease control work to a

^{*} Read at a Special Session of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

broader and more comprehensive program embracing most of the essential elements for the protection of the community's health. Until recently this expansion was due in a large measure to the pressure brought to bear upon the health officer by local groups interested in some special phase of public health work, such as tuberculosis, baby welfare, or public health nursing. This resulted in over-development in certain fields, while other services have been under-developed or omitted. Moreover, in many instances it produced a program with little or no relationship to the immediate needs of the community.

The Committee on Administrative Practice, by setting up standards of performance and suggested methods for showing the relationship of one activity to another, has enabled the health officer to approach more scientifically the problem of working out a balanced program, one designed to meet the existing situation. By a careful analysis of the public health services in his community he obtains a clearer picture of the adequacy of the present program, and he is able to build up interest in the neglected fields, or to some extent lessen the pressure for more service in others that are already well covered.

National and local agencies gain a more balanced viewpoint when confronted with a picture of the local public health situation as reflected in such a study, and become ready and willing to lend their support to the development of other activities where the need is greater.

Health Conservation Contests—The Health Conservation Contests sponsored by the U. S. Chamber of Commerce in coöperation with the Committee on Administrative Practice have had a far-reaching effect in arousing community interest in public health work. As a means of bringing about

lasting improvements in health programs of competing communities, too much confidence should not be placed in these annual competitions. Nor should a too literal interpretation be placed upon the numerical ratings of cities, as it is quite likely to breed dissatisfaction among health officers and others in the community interested in promoting sound public health service.

Consultant and Survey Service—One of the most important features of the work of the Committee on Administrative Practice is its consultant and survey service. Through its careful study of administrative practices in states, cities, and counties throughout the country, its field staff is well equipped to give expert advice on special problems confronting the health officer, or to make a detailed survey and evaluation of all services in the community, with a view to working out a more adequate and well balanced program.

When I came to New York City as Commissioner of Health, one of the immediate needs was a thorough study of the Health Department staff. It was important to know what each person was doing; how well the work was being done; what shifts in personnel could be made to bring about greater efficiency within the department. With a staff of approximately 2,500, and with many pressing administrative problems, it was obviously impossible for me, personally, to make such a study. I quite naturally turned to the Committee on Administrative Practice as the best qualified agency to undertake this work. The report which the field staff presented upon completion of an intensive personnel study has been used as a guide in making numerous changes among the staff and thus has been an important factor in increasing the efficiency of the department.

A survey and appraisal was also

made at my request by the committee's field staff, and we are now using this analysis as a basis for further re-organization of the department and in planning the program for the coming year.

Besides this as time goes on one has a basis for measuring advances or back-sliding in the department.

Time will not permit a further review of the constructive contributions of the committee. I should like to devote some time to a brief discussion of some of the things, which from my viewpoint as a health officer, I feel should be considered in planning its future program.

WHAT ARE THE FUTURE POTENTIALITIES OF THE COMMITTEE?

The Committee on Administrative Practice has exerted a wide influence in promoting the evaluation of public health activities. I believe the time has arrived when the committee should evaluate its own activities to determine which are worth while and should be continued, which should be discarded, and what new activities should be undertaken.

Free Service—The present program of the committee includes Consultant and Survey Service, which is rendered to communities at cost. There are many communities, perhaps those needing this kind of help most, which are unable to pay the cost of this service. Some way should be found for making the service of the field staff available without cost to needy cities. Take for example, a small city that has a special administrative problem. A day spent with the health officer in working out this problem would be of untold value to him, and it would not involve a great outlay of money on the part of the committee. I am strongly in favor of free service for those unable to pay, and believe that

it should be a part of the future program of the committee.

Current Information Service—One of the objectives of the committee is the supplying of information on current administrative practices. Admittedly this has not been one of its major activities. Yet I know of no greater need among health officers than some central source to which they can turn for up-to-date information on administrative procedures.

During the past year we were confronted with the question of adopting a regulation permitting the sale of vitamin D milk in New York City. It would have been extremely helpful if we could have had from the American Public Health Association a list of cities that had adopted similar ordinances and copies of such regulations.

Numerous other examples might be cited to illustrate the importance of setting up and keeping current this type of service and seeing that it really functions.

Model Public Health Ordinances—Another item which I think might be included in the committee's program is the development of model public health ordinances for states, cities, and counties. It may be argued that all states and communities will not require exactly the same ordinances. This is quite true. Nevertheless, suggested model ordinances would be exceedingly helpful as guides in drafting regulations to meet local needs. *The Model Milk Ordinance*, issued by the U. S. Public Health Service, has proved of great assistance to health officers when they were concerned with the drafting of a new milk ordinance for their city.

Evaluation of Administrative Procedures—A beginning has been made in the field of evaluating administrative procedures through the committee's studies of Prenatal Care, Scarlet Fever Control, and Diphtheria

Immunization, but there are many other fields which could be profitably explored. Such studies are time consuming and expensive; yet, on the other hand, it seems to me that the time has come when some attempt should be made to evaluate a number of administrative procedures which we have been carefully following for years without being sure of their real scientific value. The set-up of the committee lends itself admirably to the supervision of research work in this field, and this opportunity for a real contribution to the advancement of administrative practice should not be ignored.

Development of Qualitative Standards—Most of the criticism launched against the *Appraisal Forms* is that they measure quantity and not quality of service. This criticism is undoubtedly justified, although it is true that a number of items do measure quality, and in others it is implied. However, if progress is to be made in bringing about a wider acceptance of the appraisal idea and insuring a more lasting usefulness, the committee must consider introducing in future editions of the *Appraisal Forms* criteria that have a direct bearing on the character of service rendered. Furthermore, the whole question of relative importance of activities and their relationship to

the community health program should be carefully scrutinized.

More Published Reports — During the past few months the committee has issued a series of articles in the *American Journal of Public Health*, based on a study of Current Health Department Practices as reported through the Contests. These summaries provide informative data on health department expenditures and personnel. Further studies of this type with published reports of the findings should be a part of the committee's future program.

I am sure there are other health officers who, from their own experience and viewpoint, could add many helpful suggestions for increasing the usefulness of the committee.

Functioning as it does through some 14 sub-committees, the Committee on Administrative Practice offers splendid opportunities for active participation of alert and progressive public health workers in planning and carrying forward its activities. The notable success which has marked its work through the 15 years of its existence has been due in no small degree to the bringing into its service for consultation and advice men of wide experience and unbiased viewpoint. With a continuation of this policy, may I predict for the committee many years of satisfactory service.

Development of Vital Statistics in the Bureau of the Census*

HALBERT L. DUNN, M.D.

Chief Statistician, Division of Vital Statistics, Washington, D. C.

THE primary task which has faced the leaders of vital statistics in the United States for the last third of a century has been the development of the complete recording of births and deaths. In 1900 the United States was one of the few remaining countries in the realm of Western Civilization which contained large areas in which births and deaths were not registered. The difficulties facing the centralized development of vital statistics arose from the fact that the individual states were autonomous. In 1900 the Bureau of the Census, aided by the American Public Health Association, the state boards of health, and the American Medical Association, drafted a model law which the states were urged to adopt individually in order that the United States might attain a complete and uniform system of registration.

The success of the death registration area led to the establishment of a corresponding birth registration area. With the completion of both areas, by the admission of Texas in 1933, the first great task in the development of building an effective national science of vital statistics has become an accomplished fact.

In charting the course for continued advance in the field of vital statistics,

the first necessity was the creation of a new Division of Religious Statistics, General Information and Records, for the collection data not previously obtained by the Census Bureau. Dr. Murphy, formerly Chief Statistician of the Division of Vital Statistics, was asked to assume the leadership. It was felt that his invaluable knowledge of registration problems, gleaned by years of experience in the battle for a complete death and birth registration area, would do much to assure the success of this new division.

In the meantime, the Joint Advisory Committee to the Director of the Census surveyed the various questions and problems involved in charting a future course for vital statistics, worthy of the requirements of a nation such as ours—a course which might eventually result in the blazing of new trails for other nations to follow. The reorganization of the Division in accordance with the recommendations of the committee is now an accomplished fact, one with which you are all familiar.

The choice for the position of Chief Statistician for the Division was a direct result of the committee's recommendation which provided that, if possible, the chief statistician should be qualified as a physician and also as a scientist trained in the technics of biometry and interested in statistical research. The choice of Dr. Collinson for the position of Assistant Chief

* Read before the Vital Statistics Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 9, 1935.

Statistician was also a result of the committee's recommendation that the assistant chief statistician should be qualified as a physician and should also be familiar with the problems faced by the states in relation to public health as well as to vital statistics. I do not need to describe Dr. Collinson's work in connection with vital statistics and public health activities in Maryland, since he is known personally to those present at this meeting. Dr. Linder is another addition to the staff of the Division. His scientific training and publications in the field of biostatistics and psychology will materially strengthen the research activities of the Division.

The next important step taken by the Director of the Bureau of the Census was to ask for the appointment by the Secretary of Commerce of an Advisory Committee for the Division of Vital Statistics. This committee was appointed on July 29 by Secretary Roper. In the selection of the membership of the committee, an attempt was made to secure representation of leaders from among those who gather and use vital statistics.

The names of those asked to be members of the committee are as follows:

Prof. Robert E. Chaddock, Professor of Statistics at Columbia University

Louis I. Dublin, Ph.D., Vice-President of the Metropolitan Life Insurance Company

Haven Emerson, M.D., Professor of Public Health Administration at Columbia University

Lowell J. Reed, Ph.D., Professor of Biostatistics, School of Hygiene, Johns Hopkins University

Stewart G. Thompson, D.P.H., State Registrar of Vital Statistics in Florida

R. C. Williams, M.D., Assistant Surgeon General and Chief of Division of Sanitary Reports and Statistics, U. S. Public Health Service.

The first meeting of this Advisory Committee was held at the request of the Chief Statistician for Vital Sta-

tistics on September 20, 1935, in the Commerce Building at Washington, D. C. Dr. Reed was elected by the committee as its chairman, and Dr. Thompson, secretary.

The purpose of the meeting was to formulate a plan for the future development of the Division of Vital Statistics, Bureau of the Census. The committee came to the agreement that the future development of the Division should be extended along the following broad general lines:

1. Extension of field work in order to secure and maintain completeness in the registration of births and deaths, to improve the completeness and accuracy of the data noted upon the original certificates, and to promote coöperation between federal, state, and non-official agencies dealing with and interested in vital statistics.

2. Coördination of state and federal statistical office activities with the object of eliminating overlapping effort in so far as possible.

3. Development of means by which the total data in the birth and death certificate might be made readily available for special public health and scientific needs.

4. Stimulation of research within the Division by appropriate coöperation of the Division with outside scientific and public health agencies, and by building up within the Division a personnel whose principal duties will be the analysis and solution of important vital statistical problems.

EXTENSION OF FIELD WORK

The customary method of testing completeness in registration of births and deaths has been by the post card check. All states have entered the registration area only after they have passed a test in completeness of registration as indicated by post card check. It is necessary to maintain continued interest in the completeness of registration in order to create a general public consciousness of the need and value of complete registration of births and deaths. The post card method of survey undertaken with the permission and coöperation of the officials of the

state department of health is the most valuable mechanism for this purpose. A publicity campaign consisting of newspaper articles, lectures, visits to physicians, midwives, local registrars, undertakers, etc., is usually conducted as a preliminary step. It is essential that post card surveys be carried on in future even as they have in the past.

The information on the card dealing with birth consists of the factors—name of child, color, birth date, place of birth, name of parents, and address. The post card reporting deaths contains the name of decedent, color, date of death, place of death, name of informant, and address.

On the usual post card surveys this information is requested for those births and deaths which occurred during the previous 12 months. Through the courtesy of the Postal Service, one post card is sent to each family. All returned cards are checked in the state office of vital statistics against the index of births and deaths, or against the actual original certificates of births and deaths. By this means the percentage completeness of births and deaths previously recorded by the state or city registrar can be evaluated in terms of the number of births or deaths reported on the post cards.

Other methods of survey to ascertain the completeness of registration have been used, of which the principal one is that of enumeration. This method, admittedly more accurate than the post card survey, is considerably more expensive. For reasons of economy, the post card method must ordinarily be used. Its accuracy however, should be checked with that of the enumeration method from time to time. One such test has been conducted this year in the State of Georgia, and it is hoped that other comparisons of a like nature can be obtained in the near future.

There are other aids to complete registration. In all state offices cer-

tificates of death of children under 1 year could be checked against records of births to determine if the birth has been reported. This is a very simple process and can be carried out as a routine monthly office procedure. Whenever school authorities take the census of school and preschool children, the information from these schedules can be used to determine if births have been registered completely. Assistance in checking the completeness of registration can be obtained by comparison of state files with information concerning births and deaths taken from lists reported by hospitals, physicians, or undertakers. In isolated and backward areas information on births and deaths can be obtained from church records. In the registration of Indians, whether on or off government reservation, considerable gain can be made by closer coöperation with the Office of Indian Affairs.

In addition to the necessity of vigilance in maintaining completeness of registration of births and deaths, it is hoped that attention can be focused in the future upon the problem of obtaining greater completeness and accuracy of the contents of the birth and the death certificates. This is for the most part an experimental problem to be solved by special studies.

The necessity of stimulating promptness in the transmission of birth and death certificates from the local areas to the state office and from the state offices to the Vital Statistics Division of the Census Bureau is another field problem involving primarily a closer coöperation between this Division and the state offices of vital statistics.

The Division of Vital Statistics has obtained authorization for 6 medically trained field workers who will assist in the solution of these manifold problems. In the course of a year an agent would presumably work in a number of states. He would be a representative of this

Division in coördinating federal with state activities, and at the same time would serve as a medium for exchange of ideas between states.

The Division hopes to continue the regional conferences of state registrars which have proved to be of great benefit in coördinating the activities of federal and state divisions of vital statistics. Attendance at local, state, and national meetings, and visits to the states by the officials of this Division will be an additional aid in the interchange of ideas and the maintenance of a spirit of coöperation.

COÖRDINATION OF FEDERAL AND STATE OFFICE ACTIVITIES

The Division of Vital Statistics is cognizant of the extensive overlapping in activities which exists at present in the state and the federal offices of vital statistics. Both offices code the death and birth certificate completely with a consequent loss in the effective use of the clerical personnel in the respective offices. It is the desire of the Division to eliminate such overlapping activities in so far as possible. The function of the field worker in connection with this process will be invaluable. Each field worker will be trained in the practices of the U. S. Division of Vital Statistics. Consequently when he is working with the state registrars, he will be able to help in the coördination of the office activities of the state and federal divisions.

As a prerequisite to coördination of office activities, a loose-leaf instruction manual is being prepared by this Division. This manual will describe minutely every process involved in coding and punching of the information from the birth and the death certificate on the 45 column punch card which was adopted by the Division on July 1, 1935. In addition to the detailed information on coding and punching, all variations in practices in-

involved with coding of causes of death will be incorporated as part of the instruction manual. The instruction manual will be distributed to all state registrars and to others who are interested in the procedure followed by this Division. No alterations in the rules announced in the instruction manual will be made except by officially approved amendments. Such amendments will be furnished to those on the mailing list to whom the instruction manual is distributed. It is hoped that a precise written presentation of the practices of this Division will aid materially in bringing state and federal office practices into harmony.

Perhaps the one factor which is the greatest barrier in obtaining this goal is the coding of causes of death. The difficulties involved in the selection of the primary cause of death by use of the *Manual for Joint Causes of Death* are particularly complex and bewildering.

A letter was sent to the state registrars on August 30, 1935, soliciting their coöperation in a study of this question. Enthusiastic response indicated the urgency of obtaining simplification of the exceptions which have been made in the exact use of the *Manual of Joint Causes of Death*. Instructions to coders of causes of death will be included as a part of the instruction manual. The state registrars may rest assured that the rules for coding cause of death will be strictly adhered to by the Division of Vital Statistics, and that any alterations will be made only after approved amendments have been distributed to all.

The Division of Vital Statistics, acting upon the advice of its Advisory Committee, expects to study the effect which multiple causes of death have upon the method of selection of the primary cause of death by use of the *Manual of Joint Causes of Death*. With such knowledge, it will be pos-

sible to obtain an understanding of the death rates which are computed by using the primary cause of death. It is particularly desirable that such a study of the primary or contributory cause be available in connection with maternal deaths, and consequently it is anticipated such analysis can be made upon the 1935 death certificates.

GREATER AVAILABILITY OF TABULAR DATA FROM THE BIRTH AND DEATH CERTIFICATES

At present the measure of public usefulness of the Division of Vital Statistics is represented largely by tabulations which are made from the data under its jurisdiction. In the past such tabulations have been concentrated for the most part in the volumes of mortality and birth statistics. In the future it is hoped that progress can be made which will make available more extensive tabular information than exists in the printed volumes. This will be achieved by the following:

A. Making available in depository libraries tabulations which can be printed only in limited editions by mimeographic or photographic printing processes.

B. Tabulating many special tables which will be held in manuscript in the central office. A list of all such tables which can be photostated upon demand will be published.

C. Summarizing the data of individual certificates of birth and death upon summary punched cards which will make possible upon demand and with a minimum of clerical effort, unusual and manifold kinds of tabulations.

A summary card set-up signifies what the name implies; *i.e.*, a secondary set of punched cards which summarize the data for a given community and cause of death. When the data of given communities are summarized upon punch cards, the data can be recompiled with very little effort by passing the summary cards of those communities through the tabulating machinery.

It is hoped that some such plan can be devised in the immediate future so that demands for special data by public health officials or by scientists involved with specialized research interests can be answered without delay.

It is important to note that the total data on the birth and the death certificate are not completely transferred to the punched card. It is vital to the continued development of the Division that it have access to all the data on the certificates. For example: the problem of studying the effect of multiple causes of death upon the selection of the primary cause of death by the use of the *Manual of Joint Causes of Death* could not have been studied in 1935 if the detailed information upon the death certificate were not available to this Division. Likewise the study of multiple causes of death in connection with puerperal deaths could not be carried through without having access to the original certificates. Consequently, the elimination of overlapping activities between state and federal vital statistical offices should not preclude the ability of the federal Division to obtain the complete information on the original birth and death certificate.

DEVELOPMENT OF RESEARCH

In the past special studies by the federal Division have been made occasionally upon request from special organizations. Monographs have been published under the sponsorship of the Division. It is hoped that in the future a considerable amount of clerical effort, devoted at the present time to tabulation, can be released by the use of a summary punched card set-up. If this can be achieved, the time of this clerical personnel can be allocated to the functions of computation and research. The necessity for greater activity by the Division along these lines is obvious. Special study is

needed in connection with the relation of births and deaths to population and the estimates of population in intercensal years. The degree of reliability of the Division's own work is also a function for divisional research. The numerous problems involved in the allocation of death and birth by residence will be faced. Residence as well as place of death will be coded and punched on all 1935 mortality and nativity cards.

In conclusion, may I express the appreciation of the members of the

Special Advisory Committee of the Division of Vital Statistics as well as that of the Director of the Bureau of the Census and the officers of the Division of Vital Statistics for the spirit of coöperation which has been evidenced in these early months of reorganization. By joining hands with the state registrars of vital statistics and the state health officers, it is within the power of the United States to win a position in the world of vital statistics which is second to that of no other nation.

St. George, the Patron Saint of Lepers

THE legends and stories about Saint George (St. Georg, St. Jörgen) are many. The Near East, as well as England, Aragon and Portugal claim him as their patron saint. Living in the 3rd century, he belonged rather to the Christian Church as a whole than to any locality. The Catholic Church, the Anglican Church, the Greek Church, the Syrian Church, and even the Mohammedans revere him. Central Europe, too, has its legends concerning him. . . .

An old German picture from the Middle Ages illustrates the story of St. George killing a dragon with a spear. This story is found in the Golden Legend by Jacobus de Voragine, and resembles a Christianized form of the ancient legend of Perseus slaying the sea monster to save Andromeda, or of the sun god as the conqueror of darkness. More recent crusaders against leprosy have revived

the legend and refer to St. George as fighting leprosy, the dragon destroying the health of the Middle Ages. This idea has some historic significance, since in that period St. George was honored already as the patron saint of lepers, and an order named after him, the Knights of St. George, took much interest during the Middle Ages in nursing lepers.

The Second International Leprosy Conference, held in 1909 at Bergen, Norway, under the secretarial supervision of Dr. H. P. Lie, used the old legend in its emblem, and in 1932 the International Leprosy Association adopted a slightly modified form of this emblem as that of the new organization. Thus we see legends live on, modifying their forms as time and circumstances demand. . . . Lee S. Huizenga, M.D.—*International Journal of Leprosy*, pp. 337-338.

National Aspects of the Social Security Program as They Pertain to the Children's Bureau *

KATHARINE F. LENROOT

Children's Bureau, U. S. Department of Labor, Washington, D. C.

IT is a privilege and an honor to participate in the Sixty-fourth Annual Meeting of the American Public Health Association, an organization which through the years has contributed so much in inspiration, illumination and guidance to the great objective of protecting and advancing the health of the people.

It was logical and highly appropriate that measures for strengthening and extending the public health services and the special services for the health and welfare of mothers and children should be incorporated in the National Social Security Program recently authorized by Congress. Throughout the ages war, pestilence and famine have been the great specters under whose shadows men have built homes and women have borne and reared children. Civilization is still at grips with war, whose power has been vastly augmented by science. In the Western World we no longer speak of pestilence, though we are no less vitally concerned with forces menacing life and health, and we have translated famine into unemployment and economic depression.

It is unnecessary to emphasize in this

gathering the close relationship between conditions which shorten life and drain body and mind of strength and vigor, and conditions undermining economic welfare. Illness has long been recognized as one of the major causes of that poverty which persists in times of prosperity as in times of depression. Moreover, as shown by studies made by the U. S. Public Health Service in coöperation with the Milbank Memorial Fund, the incidence of sickness appears to be greatest in families whose standards of living are seriously and somewhat suddenly reduced. Long before the depression which put 8,000,000 American children under the age of 16 years on the relief rolls, the toll which poverty and economic exploitation took of the lives and welfare of children was known to be severe. The earliest studies of the Children's Bureau, dealing with infant mortality in representative industrial cities, showed that low earnings and high infant mortality rates went hand in hand. Juvenile delinquency is one manifestation of the absence of mental and social health, and there is evidence indicating that areas in our large cities having high delinquency rates also have high infant mortality rates and high incidence of communicable disease.

Security in our childhood was a creation of the family and its circle of

* Read at a Special Session under the auspices of the Health Officers Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

relatives, friends, and neighbors, with few outer guarantees. Death, illness, accident, poverty, unemployment, were individual calamities for which society made only the most meager provision. With the developing prosperity of the new century and the increasing awareness of the public of the need for community provision for health and welfare, both public and private resources for the prevention and care of illness and social distress multiplied, and great organizations of men and women lent effective support to these movements. Yet in spite of national influences expressed through federal and voluntary organizations and considerable gains in state legislation and administration, progress on the whole was uneven, varied greatly from state to state and within areas of the same state, and left large numbers of men, women, and children almost entirely outside the reach of the developing concepts of social responsibility and social protection.

Thus we came to the cataclysm of 1929 and the succeeding years, which shattered the security of the most self-confident and awakened us to widespread realization of the need to remold our economic and social life so as to afford more adequate safeguards for individual and family activities and growth. The development of policies designed to afford such safeguards has included financial, agricultural, industrial, relief, public health, social welfare, and other measures related to social well-being. The Social Security Act, approved August 14, 1935, after a year of study by the Cabinet Committee on Economic Security headed by the Secretary of Labor, and experts associated with it, is concerned with one of the major aspects of security outlined by the President in his message of January 4, 1935—"Safeguards against misfortunes which cannot be wholly eliminated in this man-made world of ours."

The Act, which, as you know, includes provision for unemployment compensation, old-age security, security for children, aid to the blind, extension of public health services, and vocational rehabilitation, is based primarily, with the exception of the titles dealing with old-age benefits, upon coöperative federal-state relationships. Its philosophy, as stated by the Secretary of Labor in her address to the Second National Conference on Labor Legislation, is that of "mutuality and coöperation." Concretely, this philosophy is expressed in coöperative relationships to be developed between the federal government and the states; the states and local government units; the official agencies within these areas of government concerned with health, education, and public welfare; and the official agencies and representatives of voluntary groups such as medical societies, public health nursing organizations, other health groups and organizations, and social welfare agencies. As a foundation for all these professional undertakings the understanding and intelligent support of great lay groups of citizens are essential. The Social Security program can be carried out only as it becomes in each state a state-wide program, clothed with specific provision for making it effective in the lives of the men, women, and children of the state, and supplemented by such other measures of social provision for human needs as experience shows to be necessary and feasible.

The Cabinet Committee on Economic Security and the committees of the House and the Senate which gave extended consideration to the Social Security proposals concurred in recognizing that the core of any social program is the child; that all parts of the Act are in a very real sense measures for the security of children; but that "in addition," in the words of the Senate Finance Committee, "there is

great need for special safeguards for many underprivileged children." The Cabinet Committee had in mind the millions of children under the age of 16 years in families receiving relief, of whom over 700,000 were in families without the presence of the normal breadwinner; the 280,500 children receiving benefits under the inadequate and uneven provisions for mothers' aid, now authorized by the laws of 46 states and the District of Columbia; the physically handicapped children numbering from 3 to 5 million; and many other classes of children receiving or in need of social protection.

The report also called attention to the economic loss and the insecurity for children resulting from the high rate of maternal deaths in the United States, and the inadequacy of prenatal and obstetrical care in both urban and rural districts. It emphasized the drastic reductions in state appropriations for maternal and child hygiene; the need for more adequate infant and child health service, especially in rural areas, where since 1929 infant mortality rates have exceeded the rates for urban areas; and the need for the development and extension of state and local programs for crippled children.

The special measures for the health and welfare of children incorporated in the Social Security Act constitute recognition of the fact that security and opportunity for children are dependent not alone upon family income but also upon parental intelligence and community provisions for the health and social services which individual families under modern conditions cannot provide by their own efforts alone.

Title IV of the Act provides for extending and strengthening state provision for needy dependent children in their own homes who have been deprived of parental support or care by reason of the death, continued absence from the home, or physical or mental

incapacity of a parent. The federal government will give aid to the states for this purpose, amounting in general to one-third of the cost of state plans approved by the Social Security Board, which is given administrative responsibility for this Title of the Act. The plans must provide for state-wide operation, must be mandatory upon local political subdivisions if administered by them, must be administered or supervised by a single state agency, must give opportunity for state review of claims denied, and must provide for efficient methods of administration. In a number of states it is necessary to amend state legislation and provide for state appropriations in accordance with the provisions of the Act, and some states have already taken such legislative action. In the development of this part of the program and of the child welfare provisions to be described later close relationships between the Children's Bureau and the Social Security Board will be maintained.

The Children's Bureau is given responsibility for the administration of Title V, except part 4 (section 531) authorizing additional appropriations for vocational rehabilitation services which are to be administered by the office already charged with this responsibility, namely, the Office of Education. The annual appropriations authorized to be administered through the Children's Bureau, under the general supervision of the Secretary of Labor, are as follows:

For grants to states.....	\$8,150,000
Maternal and child health services	3,800,000
Services for crippled children..	2,850,000
Child welfare services.....	1,500,000

An annual appropriation of \$425,000 is authorized to enable the Children's Bureau to carry on necessary administrative functions and to make such studies and investigations as are necessary to promote the efficient adminis-

tration of those portions of the Act for which the Bureau is responsible.

The primary purpose of these portions of the Act, as described in a bulletin, *Grants to States for Maternal and Child Welfare*, recently published by the Children's Bureau, is to extend and strengthen services for mothers and children in rural areas, in areas suffering from severe economic distress, and among groups in special need. These are the people who have been hitherto, for the most part, outside the reach of health and welfare services that have been more generally available in cities. In this connection it is interesting to note that whereas the urban infant mortality rate increased 1 point from 1933 to 1934 (from 57 to 58), the rural rate increased 3 points—from 59 to 62. Certain urban districts, however, still have exceedingly high rates, and programs to be developed by the states under the Act will reach some of these areas as well as the less populous portions of the country.

The amount of \$3,800,000 available for maternal and child health services as follows:

Uniform apportionment, \$20,000 to each state.....	\$1,020,000
Apportionment on basis of live births	1,800,000

These amounts, totalling \$2,820,000, are available for payment of half the total expenditure under approved state plans. In addition, \$980,000 is available for allotment by the Secretary of Labor in accordance with the financial need of each state for assistance in carrying out its plan, after the number of live births is taken into consideration.

The federal administration of this part of the Act has been placed under the immediate direction of a Maternal and Child Health Division in the Children's Bureau, headed by a physician and receiving general supervision from

the Assistant Chief of the Children's Bureau, Dr. Martha M. Eliot. State administration is vested in the state agency of health.

State funds appropriated or otherwise provided by the state itself must be made available for payment of part of the costs of approved plans. Funds appropriated or made available by political subdivisions (counties, cities, or towns) may also be counted, provided such local activities are brought into the state plan and under the general supervision of the state department of health. State or local funds used for matching any other federal appropriation cannot be counted in establishing eligibility for federal assistance under this portion of the Act.

Responsibility for initiating and developing state plans rests with the states. They are to be approved by the Chief of the Children's Bureau if they conform to certain conditions specified in the Act. These conditions include, in addition to provision of public funds as indicated earlier, provision for such methods of administration (other than those relating to selection, tenure of office, and compensation of personnel) as are necessary for the efficient operation of the plan, and such reports as may be required; and provision for extension and improvement of local maternal and child health services, for development of demonstration services in needy areas and among groups in special need, and for coöperation with medical, nursing, and welfare groups and organizations.

The general principles governing the portions of the Act relating to services to crippled children are similar to those governing maternal and child health services. The appropriation of \$2,850,000 is to be allotted, \$20,000 to each state and the remainder on the basis of numbers of crippled children in need of services and costs of furnishing services to them. Grants to the states must

be matched in full by state or state and local funds. Conditions which must be met before plans are approved include coöperation with medical, health, nursing, and welfare groups and organizations and with any agency in the state charged with administering state laws providing for vocational rehabilitation of physically handicapped children. The funds are to be used for the purpose of enabling each state to extend and improve, especially in rural areas and areas suffering from severe economic distress, services for locating crippled children and for providing medical, surgical, corrective, and other services and care, and facilities for diagnosis, hospitalization, and after-care for children who are crippled or who are suffering from conditions that lead to crippling. The funds provided are not available for the education of crippled children.

The administration of this part of the Act will be under the immediate direction of a Crippled Children's Division of the Children's Bureau, headed by a pediatrician with special experience in the development of community programs for crippled children, and receiving general supervision from the Assistant Chief of the Children's Bureau. State administration will be through a state agency having responsibility for medical care for crippled children. If several agencies are responsible, one should be designated by agreement of those concerned.

The appropriation of \$1,500,000 for child welfare, to be allotted \$10,000 to each state and the remainder on the basis of rural population, is to be available for coöperation with state public welfare agencies in establishing, extending, and strengthening, especially in predominantly rural areas, public welfare services for the protection and care of homeless, dependent, and neglected children, and children in danger of becoming delinquent. They

are to be used for payment of part of the cost of district, county, or other local child welfare services in areas predominantly rural, and for developing state services for the encouragement and assistance of adequate methods of community child welfare organization in areas predominantly rural and other areas of special need. The program will be under the immediate direction of the Child Welfare Division of the Children's Bureau, headed by a social worker.

Because of the failure of Congress to pass the Third Deficiency Appropriation Act, the program, which it had anticipated would be fully under way by this time, is still in the planning stage. Fortunately, relatively little state legislation is required to enable the states to coöperate with the Children's Bureau, provided state funds, supplemented by local funds, can be made available for the coöperative activities authorized.

The Secretary of Labor, on the recommendation of the Children's Bureau, has appointed 4 advisory committees to assist the Children's Bureau in the development of general policies. These committees, whose membership will be announced shortly, include representatives of various branches of the medical profession, public health nursing and social services. They are as follows: General Advisory Committee on Maternal and Child Welfare Services, Maternal and Child Health Advisory Committee, Advisory Committee on Services to Crippled Children, and the Child Welfare Advisory Committee. The committees will probably be called together within the next 2 months.

The Children's Bureau has appointed persons to have charge of the development of the work of the 3 divisions responsible for the coöperative activities under the Social Security program, and has assigned a few physicians and social workers as field representatives,

available for advisory services desired by the state agencies in connection with the development of state plans. It is hoped that such progress can be made in the development of plans in many states that they can be approved by the time appropriations become available, so that payments of the first grants can be made promptly. The Bureau will endeavor to give information and assistance to the states, so that the experience of the best will be made available to all, the children thus being afforded the maximum service possible. Studies and investigations will be undertaken in coöperation with state agencies in order to afford a sound basis for the development of various aspects of the program.

Administration of the three types of aid for maternal and child health and welfare will be closely integrated, for we have learned that it is impossible to divide a child's life into separate compartments; physical and mental health are mutually interdependent. The care of the crippled child is an excellent example of the need for coördination of medical, nursing, and social services. Locally, much of the work of locating and diagnosing crippled children will be carried on through maternal and child health services; nurses will assist in follow-up after discharge from hospitals; and social workers will assist in determining financial need, developing plans for boarding or institutional convalescent care, and preparing the family for the child's return. Mental hygiene services should be developed, as opportunity offers, in connection with both the health and the welfare programs.

Although specialized direction of the services planned will be given by 3 divisions in the Children's Bureau, a unified program of field service is being developed. The same physicians will be available for consultation service to the states for both the maternal and

child health and the crippled children's programs, the same public health nursing consultants for both programs and probably the same social workers for the crippled children's and child welfare programs. Close coöperation among the various federal agencies concerned in the Security program will be maintained.

Locally, a broad base of county or district public health service and social service is essential. The maternal and child health program must be developed as part of a generalized service, with specialized consultant service provided. In many areas similar relationships between specialized and generalized social services will be developed. Both generalized service and specialized service, at least of an advisory nature, are necessary if the needs of mothers and children are to be met.

The success of the undertaking will be dependent chiefly upon the extent to which the state coöperating agencies can be equipped with qualified personnel and leadership. State and local services immune from political interference, staffed with people qualified by training and experience for the work to be undertaken, and working with the full coöperation of professional and lay groups, are essential.

The facilities provided by the Act will not relieve private health or social welfare agencies of any responsibility they are now carrying. The need for generous support of private agencies will be as great as ever. Most of the services provided for mothers and children and for crippled children will be entirely outside of the large cities.

In the development of both the maternal and child health and the crippled children's programs, the understanding and coöperation of the medical profession and of specialists in public health administration are of the utmost importance. Questions involving medi-

cal relationships will be dealt with by national and state advisory committees on which the medical profession will be represented. The Children's Bureau will advise the states that evidence that medical and health groups have been consulted and are coöperating must be included in plans for state and local activities. We shall look to the members of the American Public Health Association for counsel and for assistance in placing these programs upon a secure foundation.

These activities, together with others developed through federal, state, and local participation and the coöperation of voluntary groups, will help to extend to the entire nation such safeguards as are necessary for the general health and well-being. Through them, families and communities will be strengthened in their ability to provide for their children that security and opportunity for satisfying living and achievement which is in harmony with our highest ideals.

Annual Report of Montefiore Hospital

THOSE who are interested in promoting public understanding of the place and utility of great hospitals will be fascinated by a popular edition of the Annual Report of Montefiore Hospital in New York City. The booklet is entitled, "Fannie Hurst's Visit to Montefiore," and in a very clever fashion the author has made the hospital seem a human place where, "in spite of the scientific evidence, the tremendous medical achievement, the equipped laboratories, and the high powered minds behind the façade of Montefiore, a warm human atmosphere

radiates." "It must suffice to say that by some subtle and blessed technic a hospital has become a humane as well as a human enterprise."

Fred M. Stein, Member A.P.H.A., is President of Montefiore. The hospital is a member of the United Hospital Fund in New York which is at present having an annual campaign. The booklet is beautifully illustrated with hospital scenes, and might prove an inspiration to some health department to humanize the figures which make up the ordinary health department reports.

Present Status of the Vitamin B Complex*

C. A. ELVEHJEM, PH.D.

University of Wisconsin, Madison, Wis.

IN the report¹ on "Human Requirements for Vitamins" given by your committee on nutritional problems at the annual meeting in Pasadena, only vitamin B and the antipellagric factor were included in the vitamin B complex. A survey of the recent literature makes it very evident that we must deal with more than 2 factors. Results have been obtained which indicate that the older factors are of multiple nature. Most investigators also seem inclined to include newly discovered factors in this group. It is unfortunate that factors which are not abundant in yeast and which are not readily soluble in water should be referred to as part of the B complex, but the reason is undoubtedly that a realization of their existence came with studies on vitamin B₁ or B₂.

The magnitude of the literature and the number of individual factors to be discussed is probably discouraging to those who are interested mainly in practical nutrition. However, I feel that we should be encouraged, for it is indicative that we are learning more about the constituents of our food and that we are making available more weapons to combat deficiency diseases. The greatest difficulty encountered in the study of the B complex is the lack of satisfactory methods for the assay of the factor in question. The prop-

erties of the water soluble group are so similar that any method for the elimination of one of the factors in a purified ration tends to remove all the factors, and concentrates to furnish one factor are apt to contain appreciable amounts of others. Much confusion has also arisen due to reliance entirely upon growth experiments. It is true that if an animal fails to grow on a purified ration, and a certain concentrate increases the rate of growth, we are dealing with an essential nutrient, but it is difficult to be certain that one specific factor is being dealt with. Greatest progress will be made when specific pathological symptoms can be produced in experimental animals for each of the factors.

With these limitations in mind I wish to list the factors which may be included in this group and discuss briefly the more important ones.

VITAMIN B₁

There has been a renewed interest in the assay of food materials for vitamin B₁ mainly because it has been realized that earlier determinations were complicated by the absence of other essential factors and because an international unit for vitamin B₁ has been established. Birch and Harris² have shown that vitamin B₁ is specific for the cure and prevention of bradycardia in rats and have used this method for assay work. We have found the prevention of polyneuritis in chicks fed an autoclaved natural grain diet to be very satisfactory for the

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 8, 1935.

estimation of vitamin B₁. The relative potency of materials fairly high in vitamin B₁ may not be changed much by improved methods of assay. However, foods rich in other growth factors will undoubtedly show a lower potency when assayed by methods involving prevention of polyneuritis. This is especially true in the case of liver since we have found heart muscle, kidney, and even pork skeletal muscle to be richer in this vitamin than liver. Foods low in other components of the B complex will probably show a greater vitamin B₁ content. Yeasts when properly tested show a greater variation than is generally supposed. We have found brewer's yeast to be 12 to 16 times as potent as some samples of baker's yeast. It may also be necessary to reconsider the destruction of this factor during the canning process. Results in our laboratory show that 50 to 75 per cent of the vitamin B₁ in meat products is destroyed during the canning process.

Eventually the potency of foods will be expressed in terms of crystalline vitamin B₁. However, as yet there is no agreement concerning the relation of the potency of the vitamin crystals to the international standard. Ohdake³ has reported that 1 gamma of his crystals is equal to 1 international unit. Ammerman and Waterman⁴ found that it required 5 gammas of Williams's crystals to equal 1 international unit. In our work with chicks we found 1 international unit to equal approximately 3 gammas of the Ohdake crystals.

The very recent results of Baker and Wright⁵ who used the method of Birch and Harris remind us again that vitamin B₁ is not abundant in most of our foods. Most of our fresh foods contain about 1 International unit per gram. Certain samples of yeast may run 30 to 40 units, but most of the yeast contains 10 or less units per

gram on the dry basis. Wheat germ and the embryo from other seeds run from 10 to 20 units. Pork muscle may contain as high as 8 units per gram on the dry basis or 2-3 on the fresh basis.

Cowgill⁶ has prepared a formula for the calculation of the vitamin B₁ requirement of man based on body weight. According to his figures a 70 kilo man requires about 6,000 mg. equivalents or 300 International units per day. Of course, a number of factors, such as ability to assimilate the factor from the food, body reserves, etc., will affect the requirement. The availability now of crystalline vitamin will be of great help in the treatment of certain severe cases of B₁ deficiency. The exact chemical constitution of B₁ is still unknown, although Williams and his coworkers have demonstrated the presence of 2 groups in the molecule, namely, 6 amino pyrimidine and a thiazole ring.

The physiology of B₁ activity is extremely interesting. There seems to be good evidence that it is concerned with some part of the oxidative mechanism in carbohydrate metabolism, especially in the metabolism of pyruvic acid. It is now evident that its function is not limited to the brain but that it acts on other tissues as well.

VITAMIN B₃

The existence of a factor having properties similar to those ascribed to vitamin B₃ seems quite probable. This factor was first postulated by Williams and Waterman⁷ as necessary for the growth of pigeons. Waterman and Ammerman⁸ have shown very recently that, although 3 gamma of vitamin B₁ crystals will cure the polyneuritis in pigeons fed an autoclaved wheat diet, increased amounts (as high as 160 gammas) give further increments in weight. The same workers⁹ have reported similar results in the case of rats on synthetic diets. It is entirely

possible that vitamin B₃ is also operative here since there is no reason to believe that rats and birds require different factors. In our laboratory we have found that chicks produced at certain periods of the year and fed autoclaved ration plus B₁ crystals develop severe gizzard lesions similar to those described by Dam and Schönheyder¹⁰ in chicks reared on synthetic diets. This condition was prevented by addition of unautoclaved natural foods. The stability of this factor is therefore similar to that of vitamin B₃. The importance of this factor in human nutrition cannot be discussed without further work, but if it is essential, it may be of equal importance with B₁ because it is so readily destroyed by heat and moisture.

VITAMIN B₄

In 1929, Reader¹¹ demonstrated the existence of an additional factor in the B complex which was finally designated as B₄. At first its existence was based on subnormal growth in rats receiving a B low ration plus adequate amounts of B₁ and B₂, but later definite pathological symptoms were described. Reader¹² gives the following symptoms: general muscular weakness, spastic gait, swollen paws, and a tendency to sit in a hunched position. In a later paper, Barnes, O'Brien, and Reader¹³ state that lack of coördination is the most marked symptom. Halliday¹⁴ has reported similar symptoms in rats and found the preventive factor in wheat.

Two years ago Keenan, Kline, Elvehjem, and Hart¹⁵ described a typical paralysis in chicks placed on a simplified diet of casein, dextrose, salts, yeast, and cod liver oil. The paralysis is characterized by lack of proper coördination and extreme difficulty in locomotion. Liver, brain tissue, and fresh grass were found to supply the lacking factor. Due to the similarity

of the properties of the factor necessary for chicks and that described by Reader we concluded that we were dealing with B₄.

Pappenheimer and Goettsch,¹⁶ in 1931 described a cerebellar disorder in chicks reared on simplified diets. It is quite probable that the condition is related to the B₄ deficiency we have described in chicks. The clinical behavior is very similar, and we have found pathological changes in the brain similar to those described by Pappenheimer and Goettsch.

The studies on B₄ have not been extensive enough to learn much about its properties. Preliminary work has shown that it is water soluble and very labile, especially in the presence of oxygen. It seems to be associated with the fat fraction under certain conditions but can be extracted from the fat by water. Barnes, O'Brien, and Reader¹³ described the isolation of active crystals but the crystals were essentially adenine hydrochloride. Since adenine itself is inactive, the action of their crystals must have been due to the presence of active impurities. It is interesting that considerable adenine is obtained in the final stage of the B₄ concentration. The B₄ may be related to certain adenine nucleotides or nucleosides.

The physiology of B₄ remains entirely for future experimental study. However, it is quite probable that the factor will find an important place in human nutrition and in the treatment of certain brain disorders. The fact that this vitamin is not abundant in most foods and is so easily destroyed may make it one of the more important factors in the B complex.

VITAMIN B₅

Carter, Kinnersley, and Peters¹⁷ have termed a factor necessary for maintenance nutrition in the pigeon vitamin B₅. They concluded that it

could not be identical with B₃ or B₄ because it was stable to an alkaline heating that would destroy these factors. Since it is now known that vitamin B₂ consists of more than one factor and since it is also known that birds as well as rats require vitamin B₂, the status of vitamin B₅ needs reinvestigation.

VITAMINS B₂ AND B₆

Although there is considerable controversy in the literature concerning vitamin B₂, the majority of the workers have used this term to designate the antipellagic or antidermatitis fraction of the B complex. Goldberger and Lillie¹⁸ described in 1926 the successful production of pellagra-like symptoms in rats, but most workers have encountered difficulties in the uniform production of dermatitis. The potency of the material assayed is generally based upon the rate of growth in unit time. Several workers have reported a lack of correlation between the failure of growth and the incidence of pellagra, but in spite of these observations the rate of growth has continued to be used as an index of potency.

In 1930, Norris and Ringrose¹⁹ described the production of pellagra-like symptoms in chicks. Two years later Kline, Keenan, Elvehjem and Hart²⁰ demonstrated the uniform production of similar symptoms in chicks reared on a natural grain ration heated dry at 100° C. for 144 hours. When this method for vitamin B₂ assay became available, Koehn and I turned our attention to the isolation of B₂. In the spring of 1933 we had obtained a concentrate which showed a distinct greenish fluorescence and was highly active in the prevention of pellagra in chicks. At that time the first paper by Kuhn, György, and Wagner-Jauregg²¹ on ovoflavin and the vitamin B₂ activity of this pigment became available to us. An attempt was

made, therefore, to incorporate part of the method used by these workers into our procedure. However, all preparations of flavins and lumiflavin from liver extract proved to be inactive in the prevention of pellagra. Finally, it was demonstrated²² that while the flavin was adsorbed on fuller's earth in an acid solution, the factor preventing pellagra in chicks remained in the filtrate. Upon further purification of the filtrate a practically colorless concentrate was obtained which proved active. In other fractions the flavin was removed by converting it to the lumiflavin and extracting it was chloroform without reducing the activity appreciably. The fluorescence due to the flavins in concentrates from liver extract was destroyed by exposure to sunlight or artificial light without altering the activity. Thus, the factor necessary for the prevention of pellagra in chicks is a chemical entity separate and distinct from hepatoflavin.

This introduces a very important question of nomenclature. The German workers have used vitamin B₂ synonymously with flavins without reservation. The constitution of flavins has been determined and a flavin identical with the naturally occurring one has been synthesized.^{23, 24} It is true that Kuhn and his coworkers and others have obtained increased growth in rats by the addition of flavins to the Borquin-Sherman diet, which was devised for vitamin B₂ assay. However, improved growth could be demonstrated only after the addition of extracts from yeast treated with fuller's earth to remove the flavins. It is now clear that an extract prepared from yeast in this manner still retains its antipellagic properties.

Since these workers have used only growth in rats, and we have used growth in rats, and in chicks for symptoms of pellagra, it seems logical to use B₂ for assay, the factor remaining in the filtrate after

removal of the flavins. Of course, it is necessary to demonstrate that the pellagra in chicks is similar to the pellagra in humans before this term can be accepted without reservation. We have now produced black tongue in dogs, which most workers believe to be identical with human pellagra, and have found that flavins are completely inactive in the cure of this condition while the filtrate remaining after the removal of the flavins gives immediate alleviation of the symptoms and promotes normal growth on Goldberger's diet.

Very recently three independent groups of English workers reported results which are in complete agreement with our conclusion that flavins and the antipellagic factor are two distinct factors. Chick, Copping, and Edgar²⁵ found that the addition of hepatoflavin or lactoflavin to a basal diet deprived of B₂ restored the growth in rats to a small extent but was without effect on the characteristic florid dermatitis. The supplementary substance obtained from yeast extract had no effect in restoring growth but had a slight curative effect on the dermatitis. When the flavin and supplementary material were given together, growth and cure of the dermatitis resulted. György²⁶ found lactoflavin to have no connection with the pellagra-like dermatitis in 211 rats. He also found a combination of the flavin and a supplementary substance necessary for normal performance. He prefers to continue to use B₂ for flavins and introduces a new term vitamin B₆ for the supplementary substance. Harris²⁷ also found flavins to have no antipellagic action. He suggests that be used for the complex and that no names should be given the several constituents.

Since vitamin B₂ has always been associated with human pellagra and since we have shown that the flavin-free fraction from yeast extract will cure

black tongue in dogs, which is accepted as the analogue to human pellagra, we prefer to retain vitamin B₂ for the antipellagic factor. Flavins, which are undoubtedly essential in nutrition, need not be designated by a letter because their chemical constitution is now known. At least the designation may be delayed until the exact function of flavins is known. Other factors may be part of this complex because György²⁷ has recently indicated that his B₆ is not identical with the antipellagic factor.

CONCLUSION

In conclusion we may say that the so-called vitamin B complex consists of at least 5 factors, B₁, B₂, B₃, B₄, and flavins. Much more work is necessary before we can speak definitely about the amount of these factors needed in the human diet and the use of these factors in the control of specific deficiencies. Our ideas concerning this group of vitamins will undoubtedly be changed to some extent by next year, but I hope that my brief survey will give you some idea of our knowledge of the vitamin B complex as it now stands.

Research

RESEARCH is mainly looking for things that are not there and attempting processes that will not occur. The layman has little notion of this. Experimental science is tireless fumbling and groping, or the laborious discrimination and comparison of detail. It is subject to innumerable disappointments in following trails that lead out into a boundless desert or up against barriers that it seems

hopeless to try to scale. For the scientist does not make his own landscape, as do the poets, and even many philosophers, nor can he fly hither and thither at will, but he subjects himself to the tyranny of the natural phenomena or processes that he is observing. As Bacon says, he works "according to his stuff and is limited thereby."—James Harvey Robinson, *The Humanizing of Knowledge*, 1924.

Vitamin Content of Important Foods in the Child's Diet*

* CARL R. FELLERS, PH.D., F.A.P.H.A. (*Life Member*)

Nutrition Laboratory, Massachusetts State College, Amherst, Mass.

MOTHERS of today are food conscious. They are well aware that the foods which they give their children must be adequate not only in quantity but in quality. Through the continuous activity of many public health educational organizations, the true health story of foods and diets has gradually enlightened American parents as to the nutritive requirements of their children. Newest to arrive upon the scene of food essentials, are the vitamins. Mysterious and intangible at first, these elusive yet vital substances have at last yielded most of their secrets to chemists and physicians. The functions of each vitamin are now well understood and vitamin therapy is on a sound footing.

However, there has been much public misinformation concerning them. Propaganda for this or that food product or pharmaceutical preparation, injudicious advertising and an avalanche of vitamin claims for numerous foods, particularly baby and children's foods, have made mothers and even physicians and public health officials skeptical and wary of all products and foods claiming to contain vitamins. Newspapers, magazines, radio and

semi-scientific lectures have all contributed to the confusion. As yet, few public health laboratories have seen fit to set up biological units to determine the vitamin potencies of the many preparations offered for sale in their jurisdictions. As a consequence, the public has had to rely on the truthfulness of manufacturers' claims. Of course, there has been a great deal of vitamin research carried on and reported in scientific journals, but much of this is still undigested for public consumption.

For these reasons, a short summary of some of our research findings at the Massachusetts State College on some foods of special importance to infants and children, may be of interest. Our data deal largely with vitamins C and D in milk, fruits, and vegetables, with some information on other vitamins. The methods used have been the standard U.S.P. biological assay techniques with the exception of some of our most recent work on vitamin C, which has been carried on by use of the titrametric method of Tillmans¹ as modified by Bessey and King.²

EXPERIMENTAL RESULTS

MILK

Milk is the universal food of babies and young children. It is our most nearly perfect food. Among the essential nutritive factors which are present in insufficient amounts are vitamins D

* Contribution No. 222, Massachusetts Agricultural Experiment Station. Read before a Joint Session of the Child Hygiene and Food and Nutrition Sections of the American Public Health Association, at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

and C, also iron, copper, and sometimes iodine. Because of the high incidence of rickets in this country nearly all public health officials and physicians have recorded themselves as favorable to the fortification of milk with vitamin D. The 3 ways by which this is done are: (1) irradiation, (2) feeding the cow irradiated yeast, and (3) the addition to the milk of a vitamin D concentrate, such as the unsaponifiable fraction of cod liver oil or irradiated ergosterol. All these methods have now been in more or less common use for two or three years. There is real concern in the minds of many health officers, physicians, and parents as to whether it is safe to rely on these vitaminized milks to supply the vitamin D needs of children. Many recent clinical data have demonstrated that all the forms of vitamin D milk will effectively prevent rickets in normal infants, and in most cases will cure the disease as well. While nearly all health agencies are concerned over the reliability of these vitamin D milks, few do anything about it.

In Massachusetts, we have examined a large number of samples of vitamin D milks over a period of 2 years,³ approximately 60 per cent of which were

furnished by health officers (see Table I). The data are largely self-explanatory. Normal milk contains a small but relatively constant amount of vitamin D. Pasteurization, homogenization and canning do not significantly lower the vitamin D potency. While the number of samples is small, there is seen to be a slight increase in the vitamin D potency in the summer months. Two different lots of canned irradiated evaporated milk showed about double the potency of freshly irradiated milk; *i.e.*, when such milk is reconstituted, the vitamin D potency is equal to freshly irradiated whole milk. Only 2 per cent of the 245 commercially irradiated samples were seriously below the guaranteed potency of 135 U.S.P. units (50 Steenbock units) per quart. This indicates that production methods of this form of vitamin D milk are carefully controlled so as to insure a stable and constant vitamin content. While fewer samples of yeast and vitamin D milks were examined, 7 of the 8 samples tested contained at least 400 U.S.P. units per quart. One sample contained vitamin D but in lesser amount than 400 units. Of the 4 Vitex milks assayed, only 1 was seriously below the 400 unit level.

TABLE I
VITAMIN D IN MILK

Kind of Milk	No. of Samples	Vitamin D Average	No. of Samples Below Guarantee	No. of Samples	Vitamin C. Calculated Protective Level
		U.S.P. Units			c.c.
Raw milk, May-June	4	27+	..	3	48
Raw milk, Oct.-Nov.	3	20	..	0	..
Pasteurized milk, autumn	4	20	..	2	62
Homogenized milk, pasteurized, autumn	2	20	..	1	75
Canned evaporated milk	2	27+	..	3	60
Canned evaporated irradiated milk	2	270+	0	0	..
Pasteurized irradiated milk	245	135+	5	3	71
Pasteurized fortified milk (Vitex)	4	400+	1	1	68
Certified metabolized (yeast) milk	3	400+	0	1	42
Pasteurized metabolized (yeast) milk	5	400+	1	1	83

These results indicate that constant care is required to maintain the guaranteed potencies of vitamin D milk. State department of health laboratories or other official agencies should include the routine examination of these milks with their other activities.

OTHER VITAMINS IN MILK

There is so little vitamin C in milk that until the recent introduction of the titration method for determination of ascorbic acid, it has not been possible to judge accurately the effect of pasteurization, homogenization, irradiation, etc., on the vitamin C content. In a few studies we have found that normal raw fresh milk is a very poor source of vitamin C. The calculated protective daily dose for a guinea pig is approximately 50 c.c. for summer milk. We have made no determinations on winter milk, but Hart, Steenbock, and Ellis⁴ found the protective dose was 75 c.c.

Pasteurization by the holding process destroys from 20 to 60 per cent of vitamin C. The single test made on milk homogenized at 1,200 lb. pressure showed practically no loss. King and Waugh⁵ have shown that pasteurization by the Electropure or Stamvik processes causes no appreciable destruction of vitamin C. Hess⁶ found a pint of fresh milk effectively prevented infantile scurvy. Probably a quart of pasteurized milk would be required. Lavaille,⁷ in France, found no appreciable loss of vitamin C in canned evaporated milk. Our own results indicate that canned evaporated milk has a calculated protective level of from 35 to 80 c.c., or roughly the same as fresh milk.

There is no evidence that vitamin A is injured by the usual manufacturing processes. Vitamins B and G, according to Dutcher, Guerrant, and McKelvey⁸ are injured somewhat by heat, but are remarkably constant in milk

throughout the year. Pasteurization destroyed a maximum of 38 per cent of the vitamin B in milk. Krauss, Erb, and Washburn⁹ found the loss of vitamin B due to pasteurization was about 25 per cent. While it is comforting to know that vitamins C, B, and G are present in milk, we do not ordinarily urge the use of milk because of their presence. Vitamins A and D are much more important in this food.

VITAMIN C IN FRUITS AND FRUIT PRODUCTS

Fruits are usually given to infants and children because of their antiscorbutic activity and laxative action; hence we are concerned mainly with the vitamin C content. We have made many vitamin C assays using the standard Sherman guinea pig technic. During the present summer we have compared the new titration method for ascorbic acid^{1,2} with the biological assay and have found very good agreement in the case of most fruits and vegetables. We have used pure ascorbic acid as a standard and have verified previously reported findings that 0.5 mg. of ascorbic acid is equivalent to 1.1 c.c. of fresh lemon juice. This amount is fully protective against scurvy for a young guinea pig. Calculation of protective doses is therefore relatively simple if we know the ascorbic acid content of a food.

The data are presented in Table II. The high antiscorbutic potency of citrus fruits, tomatoes, strawberries, rhubarb, and certain apple varieties such as Baldwin, Northern Spy, Ben Davis, and Winesap, are fully demonstrated. The canned citrus¹⁰ and tomato products retain their vitamin C remarkably well and may be used in place of the fresh fruit. The juices are almost as rich in vitamin C as the fruits. Home canned tomatoes are the equal of those commercially canned.¹¹ Fresh apple cider is a good antiscorbutic, but

* Determined by titration method, using pure ascorbic acid as standard

preserved or bottled cider is poor. Baked apples retain their vitamin C content while apple sauce, either home prepared or the commercially canned product, has very little. Prunes and grapes show practically no vitamin C.

In summarizing these data it appears that the present custom of using citrus or tomato antiscorbutics is well founded and reliable. Our results show that other available fresh, frozen, and canned fruits or vegetables which are satisfactory secondary sources of vitamin C are blueberries,¹² strawberries,¹³ asparagus,¹⁴ apples,¹⁵ and cranberries.¹⁶

VITAMIN C STUDIES ON VEGETABLES

The use of fresh cooked, canned, and sieved (puréed) vegetables for infants and young children has been increasing. Besides the mineral and bulk values of these vegetables, the vitamins are of primary importance. Our work has been largely with vitamin C, although vitamin A has also been determined for a few vegetables. Both the Sherman guinea pig technic and the Bessey and King² direct titration of ascorbic were used. For most vegetables the latter method gives results entirely in accord with the animal bio-assay.

We have compiled data on fresh cooked, frozen cooked, canned, and canned sieved vegetables in Table III. In general our results are in agreement with those of Hoff¹⁷ who showed that cooking and canning are very destructive to the vitamin C of vegetables. Peas, asparagus, lima beans, and spinach are excellent sources of vitamin C in the raw state but lose a large percentage of the vitamin during processing. Freezing is much less injurious to the vitamin C than canning, although vegetables are pre-cooked (blanched) to inactivate enzymes previous to freezing. Little additional loss of vitamin C occurs during the time the vegetable is held in freezing storage,

but slight additional losses occur when the frozen products are cooked. In peas, spinach, and lima beans, the loss due to freezing is 40-65 per cent after cooking, while those incurred in canning are 75 to 90 per cent. This does not mean that cooked or canned vegetables are not suitable sources of vitamin C, since in spite of the large losses incurred during the heat treatments a considerable amount of vitamin C remains. Nearly all the vegetables examined would be classed as fair to good antiscorbutics, even after heat treatment.

Sieved vegetables for baby foods have been prominently advertised and sold during the past few years. Data obtained on several brands of these products show that they are quite similar, though usually poorer in vitamin C than the plain canned vegetables. The claims on the labels were usually

limited to a statement that the product contained the vitamin. So long as mothers do not rely on these products as potent antiscorbutics, there seems to be no cause for complaint from a public health viewpoint.

OTHER VITAMINS IN VEGETABLES

Hanning^{18, 19} found canned, strained vegetables to be good sources of vitamins A, B, and G. Apparently the heat treatments in cooking and canning are not greatly injurious to these vitamins. We found vitamin A of asparagus and spinach was uninjured by either cooking or canning. Hence, aside from a partial destruction of the vitamin C, cooked and canned vegetables retain, for the most part, the other vitamins.

SUMMARY

1. Fresh, pasteurized, and canned evaporated milks contain from 20 to more than 27 U.S.P. units of vitamin D per quart. Pasteurization and homogenization have no effect on the vitamin D potency of milk.

2. Of the 245 samples of irradiated milk assayed, only 5 were seriously below the 135 unit level.

3. One of the 8 samples of metabolized (yeast) milk and 1 of the 4 samples of fortified (Vitex) milk contained less than 400 U.S.P. units of vitamin D per quart.

4. Canned evaporated irradiated milk contained at least 270 units per quart.

5. Forty-three samples of fresh or manufactured fruit products, as well as the acid vegetables tomatoes and rhubarb, were examined for vitamin C content. In general, fresh and canned citrus fruits, tomatoes, and certain apple varieties (Baldwin, Northern Spy, Ben Davis and Winesap), as well as their juices, are excellent antiscorbutics.

6. Grapes, grape juice, peaches, cherries, prunes, pears, and certain varieties of apples (Tolman, McIntosh, Delicious and Jonathan), are poor sources of vitamin C. Fresh and canned pineapple as well as pineapple juice are of moderate value as antiscorbutics.

7. While raw, non-acid vegetables are usually good antiscorbutics, cooking and canning are very destructive to vitamin C. During a short cooking period, peas, asparagus, lima beans, and spinach lose 40 to 80 per cent of their vitamin C. The loss

TABLE III.

VITAMIN C IN VEGETABLES AND CANNED SIEVED VEGETABLES

	No. of Samples	Protective Level Grams
Fresh peas, cooked	32	3.6
Frozen peas, cooked	40	4.6
Canned peas	13	8.8
Canned sieved peas *	4	14.6
Fresh green asparagus, cooked	9	8.0
Frozen green asparagus, cooked	9	8.0
Canned green asparagus	3	10.0
Canned sieved asparagus *	2	18.0
Fresh spinach, cooked	3	8.0
Frozen spinach, cooked	3	6.5
Canned spinach	5	7.5
Canned sieved spinach *	4	5.5
Snap beans, cooked *	1	11.0
Canned snap beans *	2	13.0
Canned sieved snap beans *	2	15.0
Fresh lima beans, cooked	5	3.3
Frozen lima beans, cooked	7	3.5
Canned lima beans	7	8.5
Fresh carrots, cooked *	2	12.0
Canned sieved carrots *	2	20.0
Fresh beets, cooked	2	10.0
Canned sieved beets	2	13.0

* Determined by titration method, using pure ascorbic acid as standard

in canning may vary from 60 to 90 per cent.

8. Cooked, frozen vegetables are slightly lower in vitamin C than fresh cooked, but are considerably higher than the canned vegetable which has been heated for the table.

9. Canned, sieved (puréed) vegetable baby foods have the same or lower vitamin C values than the unstrained canned vegetable. In spite of the destructive action of heat on vitamin C in vegetables, sufficient amounts are retained to be of distinct antiscorbutic value.

CONCLUSION

This study furnishes experimental proof that the modern choice of foods for infants and young children, from a vitamin viewpoint, is well founded.

THE aim of education is the getting to know on all matters which concern us the best which has been thought and said in the world; and

through this knowledge turning a stream of fresh and free thought upon our stock notions and habits.—*Matthew Arnold.*

Some New Emphases in Public Health Nursing^{*}

ALMA C. HAUPT, R.N., F.A.P.H.A.

*Acting General Director, National Organization for Public Health Nursing,
New York, N. Y.*

TO appreciate what may be new in public health nursing, let us look back to the good old days of 1930 and through the ensuing years to the present. Our mirrors for reflecting the pictures of these years are various studies and reports of governmental health and welfare agencies and private national organizations concerned with health and with public health nursing.

Before we look at the picture, however, it may be well to consider what public health nursing had to offer as safeguards against the onslaughts of the depression. There were 20,000 public health nurses in 1931 as compared with at least 60,000 needed then and now. Of these, 52 per cent were employed by official agencies and 48 per cent by private organizations. We had also the following printed statements of standards in the public health nursing field, *Objectives in Public Health Nursing*, manuals of procedure for both nurses and board members, *Minimum Qualifications for Those Appointed to Positions in Public Health Nursing*, *Outline for Appraisal of Public Health Nursing*, a detailed report on the method of computing the cost of a visit, suggested records and report forms. During the very heat of the

fray in 1934, the *Survey of Public Health Nursing*¹ was published to show us how far we had put our standards into practice and how far we still had to go.

What, then, has happened to public health nursing? We have comparative figures on changes in personnel, salaries, the income and expenditures of private agencies, visits by public health nurses and visits by patients to clinics.

Figure I shows the changes in number of public health nurses employed and changes in salary. This is based on a comparison between the count of 15,915 public health nurses, exclusive of industry, as given in the National Organization for Public Health Nursing

FIGURE I

CHANGES IN NUMBER OF PUBLIC HEALTH NURSES AND IN SALARIES SINCE 1931

^{*} Read before the Public Health Nursing Section of the American Public Health Association, at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

Census of 1931,² the yearly review studies of the N.O.P.H.N.³ made in 1933, 1934, and 1935, and the annual salary studies of the N.O.P.H.N.⁴ In general, since 1931, there has been a loss of 5.4 per cent in total number of nurses employed which in actual numbers is 853.

Another glimpse of this same question of personnel is given in a comparison of the percentage of agencies reporting changes in size of staff. From 1932 on, more agencies reported decreases than increases until 1935 when for the period up to May 1 the percentage of reporting increases exceeds those reporting decreases.

Data on salaries paid to public health nurses are available for each year from 1932 through 1935⁴ as shown in Figure I. The median salary is recorded, meaning that the number of nurses receiving less than that salary is the same as the number receiving more. For Health Departments and Public Health Nursing Associations (the private agencies) the median in 1932 was \$135 a month. This dropped gradually to \$120 a month in 1934 and

in 1935 has been raised to \$125. The median salaries of school nurses employed by boards of education and health departments ranged from \$1,760 a year in 1932 to \$1,400 in 1934 with an increase to \$1,500 in 1935. We may therefore conclude that salaries reached their low level in 1934 and are on the upgrade but still 8 per cent below the 1932 level.

The total income and expenditure of agencies is an important index of the effects of the depression. Dr. Joseph W. Mountin shows the following picture of the average per capita expenditure by health departments⁵ on basis of figures reported in the Inter-Chamber Health Conservation Contests: 1931—appropriations maintained, 1932—some reduction, 1933—drastic cuts with budgets approaching those reported for 1923.

Another study⁶ indicates that the average per capita expenditure for public health in 1929 was \$1.00 per capita per year, that it sank in 1934 to \$.70. Contrast this with the \$2.00 per capita expenditure generally recognized as a minimum for adequate health protection and with the fact that up to one-half of this amount is needed for public health nursing!

Unfortunately, as Dr. W. Frank Walker has pointed out in his article, *Analysis of Public Health Expenditures by Geographic Subdivisions*,⁷ "it was not possible to isolate in health department budgets the cost of public health nursing." However, the N.O.P.H.N. has some valuable figures³ regarding income and expenditures of a representative group of private agencies for the years 1932, 1933, and 1934. Income changes are shown in Figure II. In 1933 there was a decrease in income of 10 per cent from that in 1932. In 1934 there was an increase over the previous year of 2.6 per cent. Analyzing this income for per cent derived from various sources

FIGURE II

PER CENT CHANGE IN TOTAL INCOME AND IN AMOUNTS RECEIVED FROM VARIOUS SOURCES OF INCOME BY PRIVATE PUBLIC HEALTH NURSING AGENCIES—1932-1934

in 1932 and in 1934, we find that the per cent from tax funds increased from 9 to 11 per cent, capital funds from 6 to 8 per cent, and contributions from 53 to 55 per cent. Earnings from patients' fees and contracts for service were the only source that declined and this went down from 31 per cent in 1932 to 26 per cent in 1934. The percentage of the earned income paid by insurance companies in 1932 was 83 and in 1934, 77. From recent figures of the Metropolitan Life Insurance Company we learn that the expense for its nursing service to policy holders has taken an upward turn, increasing from 1934 to the first 8 months in 1935 by 10 per cent. It is interesting and significant to know that the percentage of private agencies receiving some tax support has steadily increased from 60 in 1932 to 69 in 1934.

If the private agencies on the whole suffered a 10 per cent decrease in income in 1933, made up only by a 2.6 per cent increase in 1934, let us see how they "took it." The total decrease in expenditures in 1933 was 11 per cent and the increase in 1934 only 1 per cent. This would seem to indicate a conscientious program of budget balancing on the part of the private agencies. Salaries were 83 per cent of the total in 1932 and 82 per cent in 1934. Can we not say then that it was the nurses themselves who took the brunt of adjustment. Their salaries were the biggest budget items and the most vulnerable points of attack.

Briefly, we have the picture of 853 less nurses now than in 1931, a slight beginning at replacing that reduction; there was a considerable drop in amounts paid for salaries, with 1935 bringing a slight increase. Incomes in a group of private agencies fell 10 per cent in 1933 and were restored 2.6 per cent in 1934. The most important increase in budgets of the private agencies has come from additional tax

support; the largest decrease has been in earned income from patients and from insurance contracts. In adjusting to these changes, the private agencies tried to balance their budgets chiefly by reducing staff, reducing salaries, and making all possible economies.

At the same time that all this has been happening, the economic situation among American families has brought increased need and demand for public health nursing service. Space does not permit a review of studies made of health and the depression. Suffice it to mention the reports of the U. S. Public Health Service and the Milbank Memorial Fund showing that there is 50 per cent more illness among the "poor" than among those in "comfortable" circumstances.⁸ The Children's Bureau⁹ reports the total relief expenditures from public and private funds in 120 urban areas to have risen from January, 1929, to July, 1935, from 4 to well over 60 million dollars. The trend as indicated by Children's Bureau charts is still upward.

FIGURE III

PER CENT CHANGE IN NUMBER OF VISITS BY PUBLIC HEALTH NURSES IN 13 PUBLIC AND 24 PRIVATE AGENCIES, JAN.-JUNE, 1929 TO JAN.-JUNE, 1935, AS REPORTED TO CHILDREN'S BUREAU, U. S. DEPARTMENT OF LABOR

We are indebted to the Children's Bureau for the best figures available as to the effects of the depression on the number of visits made by public health nurses.¹⁰ Figure III shows the tremendous increase in number of home visits made by public health nurses. It is worthy of note that pay service has decreased and free service has greatly increased. An even more appalling increase is indicated in the number of visits by patients to clinics and health conferences where public health nursing service is involved. Changes in visits and cases are reported by the Metropolitan Life Insurance Company as follows:

VISITS AND CASES REPORTED BY VISITING NURSE ASSOCIATIONS TO THE METROPOLITAN DURING THE FIRST 8 MONTHS OF 1935, AND THE CORRESPONDING PERIOD OF 1934

	1934 Associations	1935 Associations	Per Cent Change
Cases (Incl. Mat. & H.S.)	253,519	274,997	+8%
Total Visits	1,442,952½	1,490,945½	+3%

The Metropolitan Life Insurance Company further emphasizes the situation which is making new demands on public health nursing. In its May 1934 *Bulletin*¹¹ the age distribution of the population was given as follows:

1,850 under 20 years	52.5%
over 65 years	2.6%
1,930 under 20 years	38.8%
over 65 years	5.4%

The June 1935 *Bulletin*¹² states that for the first time in 10 years the birth rate increased; in the previous 10 years this rate had dropped approximately 26 per cent, or an average of 2.6 per cent per year. Between 1933 and 1934 it rose 3 per cent, which may be just a temporary rise. Thus a changing age population and an increased birth rate raises for public health nursing agencies the problem of more nursing care for the aged and a greater volume of maternity and child welfare work.

These varying conditions make de-

mands on all forms of health activities and all types of public health organizations. Public health nursing is but a part of the whole machinery. As such it has made many adjustments in actual content and program which are not so easily recorded as the statistical data given above. However, the Adjustments Committee of the N.O.P.H.N. through a series of questionnaires has tried to keep its "finger on the pulse" of program changes. It is not too much to say that public health nursing agencies have attempted to preserve a service of high standard and to adjust to the most economic and effective administration. According to our reports, there has been little change in nursing under boards of education. Under health departments and in the private agencies, public health nurses have given more time to clinics and more to bedside care with corresponding reduction in time spent in purely "educational" activities. However, this new distribution of activities has led to a deepening appreciation of the idea that every contact the nurse has with the family, whether in the clinic, school or home, should be educational and productive. There seems to be a better appreciation today that the nurse teaches best by "doing." Also the increase of clinic contact has two positive advantages: (1) The family takes the initiative in seeking clinic service. Presumably the family wants the service enough to come and get it. Too often in the past, families have relied on nurses to bring the service to their very doors. (2) The clinic contact from the public health nursing standpoint also saves the nurse's travel time and hence expense. Certainly home visits are and always will be necessary, but clinics and conferences in nurses' offices can be made increasingly educational and valuable.

Another change has been less routinized service in terms of spacing

of visits and a greater attempt to understand the individual needs of each family. We have learned much (and still have much to learn) from the mental hygiene field about human relations and family problems. The very problems themselves have made us turn to coworkers in related fields for help. Public health nurses have seen more mental distress; increased want; more nutritional disturbances; greater need for bedside care in the homes, especially for mothers; communicable disease cases, and the aged sick.

Inevitably, public health nurses with depleted ranks and more demand for service have looked for help. That help has been chiefly the families themselves. The nurses have had a new impetus to teach members of the families to live hygienically, to use preventive measures for the control of communicable diseases, and to care for each other when sick. Thus a great coöperative enterprise has been going on between public health nurses and the families they serve.

Three major lessons we have learned from our struggles during the depression are pointed out in *The Survey of Public Health Nursing*¹:

First, to be better teachers of public health, nurses need better preparation in schools of nursing, in postgraduate courses, and through expert nursing supervision and teaching in the agencies employing them.

Second, our organization picture is confused and chaotic in many cities because too many agencies employ public health nurses. Our survey suggests that large cities experiment with but two agencies; one the health department whose nurses help in the control of communicable diseases, and the health education of all age groups; the other a private agency offering bedside nursing as a part of a family health service. One agency may be sufficient in small communities and rural areas.

Third, we increasingly need the help of laymen for interpretation and support of public health nursing service, whether that service be given by the public or the private agency.

Such is a sketchy picture of public health nursing since 1930. But this is not complete without turning on it the spotlight of the federal agencies that add new color. In 1933, the Federal Emergency Relief Administration through Rules and Regulations No. 7¹³ made it permissible for public relief agencies to provide bedside nursing to families on relief. Such nursing could be paid for by public relief funds and bought from whatever local agency offered the service. Thus nursing care in illness was formally recognized as a necessity along with food, clothing, shelter, and medical service. Also private agencies could be used. This may be one reason why the tax support of private agencies has increased. The N.O.P.H.N. was consulted by the F.E.R.A. in planning this program and was called into vigorous action by many states and communities in putting it into effect. Provision was made in Rules and Regulations No. 7 for the setting up of state advisory committees of the professions involved. As the federal plan was permissive rather than mandatory, there is much variation state by state, but the principles involved have been effectively carried out in many communities, and from the standpoint of public health nursing seem sound.

Entirely separate from Rules and Regulations No. 7, and quite different in purpose, are the three federal plans for putting the unemployed back to work. The Civil Works Program was launched in the fall of 1933. This was applied to nurses as well as to other types of the unemployed. Projects were set up and it is estimated that out of a total of 8,000 unemployed nurses in the country, 6,000 nurses were put to work. Of these some two-thirds

went into public health nursing although many had had no previous special preparation for this work.

Immediately the three national nursing organizations (the American Nurses' Association, the National League of Nursing Education, and the National Organization for Public Health Nursing) set up "safeguards" in which the F.E.R.A. cooperated. These were that

1. The qualifications of nurses be passed upon by a professional group of nurses.

2. Nurses be assigned where possible to existing agencies rather than setting up new agencies.

3. All nurses be under qualified nurse supervision.

4. Projects be selected in relation to community needs and the ability of the nurses to carry them out.

A dramatic picture could be drawn of overzealous ambitions, confusion, misunderstandings, etc. Suffice it to say, that on the whole much good has been accomplished. Tribute is due the advisory nurses of state health departments, the administrators, supervisors, field nurses, and board members of local agencies who plunged suddenly into the game of helping new and often raw recruits so effectively that harm was prevented, and much progress has been made.

C.W.A. and C.W.S. were shortly followed by nursing projects under state E.R.A.'s. I need only refer you to reports from 47 out of 48 states in *Public Health Nursing*¹⁴ for a graphic description of their struggles. And today these struggles are going on under the Works Progress Administration. Fortunately, the number of unemployed nurses is lessened; fortunately the nurses in projects proved themselves; and fortunately the "safeguards" are more respected today than ever before.

However, with the changing emphasis from direct relief by the federal gov-

ernment to state and local initiative and responsibility for all who are in distress, public health nursing groups and their lay friends, in states and localities, have a new opportunity to explain again the fundamental principles of public health nursing, and to make public health nursing fit into the work program. There are many hazards to standards at the present time and many "new alignments" to be faced.

Out of all of this emergency service comes the hope, even though long deferred, of the Social Security Program. We rejoiced when in 1934 the U. S. Public Health Service appointed Pearl McIver as Associate Public Health Nursing Analyst to assist state health departments in the development of state-wide public health nursing services. We look forward to the day when the Children's Bureau too will have a public health nursing consultant for its maternity, child health, and orthopedic programs.

One of the most gratifying signs of the times is that the U. S. Public Health Service, the Children's Bureau, and the Health Department of the District of Columbia all have cooperated in setting up new federal civil service classifications for public health nursing positions which will guarantee the best possible leadership and set a fine example for other groups to follow.

Things are stirring in public health nursing. We are facing "new alignments." Closer relationships are developing between public health nursing and the medical profession. We are seeing a new place for ourselves in relation to social workers. We appreciate that public health nursing is not an entity in itself but an integral part of the whole health machinery. We realize that today we are more dependent than ever on an interested, informed, and generous public.

Many a rural area is aware for the first time of its need for public health

nursing service. Many cities realize their insufficiency. Agencies want to give better service and nurses want to be better prepared. There is much that is new in public health nursing. The future of this service requires a fine balance between allegiance to accepted standards and "fundamental principles" and an experimental attitude to adapt them to the changing and new needs of our present and our future day. May we always be willing to experiment!

A Retrogressive Trend

SINCE the war, the annual matriculation at medical colleges has shown a progressive increase which threatens to undermine the important reforms accomplished by the Council on Medical Education of the A.M.A. From 18,200 in 1925, the number of medical students has grown to close to 23,000 in 1935. This figure is not far removed from the enormous enrollments of the early part of the century.

An increase on this scale, which is not justified by any public need, must inevitably entail an impairment of the

standards of medical education. Matriculates are chosen with less discrimination and the student body falls short of the scholastic and personal level achieved by more restricted admissions.

Fortunately, the number of schools has not kept pace with the growing matriculation and the colleges in existence are, on the whole, superior institutions; but their facilities are not equal to the sharp rise in enrollments.

Immunological Application of Placental Extracts*

ELLIOTT S. ROBINSON, M.D., F.A.P.H.A., AND CHARLES F. MCKHANN, M.D.

Director, Antitoxin and Vaccine Laboratory, Massachusetts Department of Public Health; and Assistant Professor of Pediatrics, Harvard Medical School, Boston, Mass.

MOST of our work with placental extract has been directed to the control of measles; so certain aspects of this disease should be discussed first in order to give an idea of the problems involved. The importance of measles is easily seen in the morbidity records of Massachusetts, for in 2 of the past 10 years there have been reported upward of 40,000 cases a year, and in none of the last 10 years has the number of cases fallen below 13,000. The actual number of cases of measles is undoubtedly larger than these figures indicate. It is true that the number of deaths from measles is by no means large, for the fatality rate has varied from 0.2 per 100 cases reported up to 1.2 per 100 cases reported, but there have been in Massachusetts about 1,500 deaths from this disease during the years 1925 to 1934.

The danger from measles lies in the complications, usually due to secondary infections, which may have a fatal outcome. Of these, by far the most important are bronchial pneumonia with its resultant empyema; and infections of the middle ear, either otitis or mastoiditis. Other dangerous but less

frequent complications are tuberculosis, enteritis, noma, and encephalitis.

It has been known for some time that measles is most dangerous in children between the ages of 1 and 4 years, particularly if malnourishment, tuberculosis, or other acute or chronic illnesses are also present. Children of these ages should be protected against measles if it is at all possible. Protection is sometimes desirable even in those above the age of 4. Infants under the age of 5 months seldom contract measles unless perchance the mother has not had the disease.

The control of measles by the ordinary public health measures of isolation, placarding, and quarantine is ineffective. The need of a practical method of active immunization is obvious, but so far no generally applicable active immunization method has been suggested, and until such a method is available, there is need of using such methods of passive immunization which are suitable and available.

The methods of passive immunization that have been suggested are the injection of convalescent serum, the serum or whole blood of immune adults, and finally, the one in which we are most interested at the moment, placental extract. Of these, adult immune

* Read before the Epidemiology Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 10, 1935.

FIGURE I

Usual Course of Measles

serum and adult immune whole blood are distinctly less to be favored than either convalescent serum or placental extract, largely because the potency of the adult serum or blood tends to vary widely and the doses required for effective passive immunization are large, usually 15 to 20 c.c. for serum, and 30 to 40 c.c. for whole blood. In contrast to this the dose of convalescent serum is usually about 4 to 6 c.c., and of placental extract about the same. The difficulty with convalescent serum is that the supply is limited, and as measles is a disease of childhood, the possible donors of convalescent serum are usually small, and only small amounts of blood may be safely taken from them.

Several factors influence the effective dosage in any of these products. First, there is the question of potency, and in this respect, convalescent serum and placental extract are usually preferable to either adult immune serum or adult whole blood. Perhaps next in importance is the time of ad-

ministration during the incubation period. Any of these products if given early in the incubation period will very often prevent measles, but they are less efficacious in this respect if given later in the incubation period. This difficulty can be offset to some extent by using larger doses of serum when administration is delayed. Another factor is the age and weight of the patient, for in general the older the child the larger it is, and the larger the child the larger the dose of serum necessary to give an adequate concentration of antibodies to afford reasonably efficient passive immunization. Possibly as important as any of these factors is the degree of exposure. This has been brought out definitely both in McKhann's previous work and also in the recent papers by Schick and Karelitz.¹ All of these authors agree that the exposure sustained in such institutions as hospitals or schools is less likely to cause infection than is that to another child in the same family at home. Schick and Karelitz have extended this

TABLE I

PATIENTS TREATED FOR PREVENTION OR MODIFICATION OF MEASLES WITH ADULT SERUM, CONVALESCENT SERUM, AND PLACENTAL EXTRACT

<i>Procedure</i>	<i>Number of Cases</i>	<i>Protected</i>		<i>Modified</i>		<i>Failed</i>	
Adult Serum	584	329	56.4%	139	23.8%	116	19.8%
Convalescent Serum	1,627	1,227	75.4%	273	16.8%	127	7.8%
Placental Extract	1,628	1,138	69.9%	417	25.6%	73	4.5%

Figures for adult serum and convalescent serum collected from the literature.

observation to show that the economic status of the home is also important, inasmuch as the exposure is more intimate and therefore more likely to give rise to an infection in the more crowded home.

By varying the factors of size of dose and time of administration, it is possible to prevent the disease entirely or to modify it. If the disease is prevented entirely, the immunity is purely passive and temporary, lasting from 3 to 6 weeks only. Such a method of administration is indicated for institutional outbreaks and for individual children temporarily exposed to the disease, who are debilitated, acutely or chronically ill, or tuberculous.

Of greater value from the standpoint of public health control of the disease is its modification by the use of serum. It is believed that an attack of modified measles will give an immunity which is usually permanent. The severity of the disease is reduced by modification to the point where it is no longer particularly serious. It is true that the incubation period may be somewhat prolonged, but this is generally not a matter of great moment. Complications and sequelae are few and usually trivial. Modification is indicated for exposed normal, healthy children. Figure I indicates the portions of the incubation period in which protection or modification of the disease may be expected to follow injection of serum or placental extract. Briefly, if serum is given in an adequate dose during the first 5 days of the incubation period,

one may expect that the child injected will not develop the disease. If, however, the administration of serum or of extract is delayed until the 5th to the 8th or 9th day, modification of the disease is more likely. If the serum or extract is given on the 9th day or later, it may have little or no effect. This carries us up through the pre-eruptive stage of measles. Serum or extract given as a therapeutic measure after the eruption appears has no pronounced effect.

Table I shows the effect of adult serum, of convalescent serum, and of placental extract when given for protection or modification. These figures include both hospital and home exposures. The important point of this table is that the adult serum failed either to protect or modify about 20 per cent of the cases, convalescent serum failed in about 8 per cent, and placental extract in about 4½ per cent.

Table II gives a more detailed picture of the effect of placental extract. In the first line across the table is seen the result of extract given during the first 4 days of exposure for the purpose of protecting the child entirely against the development of measles. Sixty-four per cent of the children were protected, and a further 31 per cent showed a definite modification of the disease. In only 5 per cent was there no protection and no modification. The administration of placental extract to produce modification of the disease is a somewhat more difficult problem inasmuch as it is quite possible to give too

TABLE II

PLACENTAL EXTRACT FOR PREVENTION OR MODIFICATION OF MEASLES
INTRAMUSCULAR INJECTION

<i>Intimate Exposure</i>	<i>Day of Exposure</i>		<i>Protected</i>	<i>Modified</i>	<i>Failed</i>	<i>Total</i>
Given to Protect	1- 4	{ No. 171	83	14	268	
		{ % 63.8	31.0	5.2		
Given to Modify	5-12	{ No. 264	283	42	589	
		{ % 44.8	48.1	7.1		
<i>All Exposures</i>	1-12	{ No. 1,138	417	73	1,628	
		{ % 69.9	25.6	4.5		

The figures for intimate exposure include children exposed at home to a brother or sister, or to a roommate in a boarding school, under which conditions 90 per cent of non-immune children may be expected to acquire the disease. In addition any child exposed at school who develops measles has been transferred to the intimate exposure group. This increases the entire number of failures in this group, but it seems to be fair in that it shows they actually were exposed to the disease.

much extract, or give it too early, and so get complete protection, as well as to give an insufficient amount or give it too late, and so fail to get any modification at all. In the present group of 589 children only 48.1 per cent showed a definite modification of the disease, but a further 45 per cent were completely protected. In 7 per cent there was no protection or modification. It should be remembered that the foregoing figures refer to children who were intimately exposed to the disease. If we include all children who received extract, 1,628, the proportion protected entirely is 70 per cent, a further 25 per cent showed modification of the disease, and 4.5 per cent showed neither protection nor modification. These figures are included here chiefly to show that the percentage of failures is less when all types of exposures are included.

The administration of placental extract intramuscularly is followed in

some instances by local and general reactions. Table III shows that somewhat more than 60 per cent of the children have no reactions of either type following the administration of extract; slightly less than one-third have a local reaction; about one-eighth have a febrile reaction of some sort or other; while only about 4 per cent suffer a local reaction great enough to be classified as moderately severe; and in only 2.5 per cent does the temperature go above 101°. Since some children had both types of reaction it seems safe to say that in only about 5 per cent was there a reaction that by any classification could be considered a moderately severe one.

The practice in certain parts of the world of feeding children dried placenta as a remedy for various ailments suggested the use of our placental extract by mouth. We have records of 109 children (Table IV) intimately exposed to measles to whom

placental extract was so administered. Of these, 33 were given the extract to prevent the disease, and in 14 this was accomplished. In 8 others, modification resulted, but in 11 no benefit was obtained. In a group of 76, to whom the extract had been given with the idea of modifying the disease, it was entirely prevented in 16, modified in 40, and failed either to modify or protect in 20. As might be expected, the results of oral administration were not so good as intramuscular injection, but, on the other hand, the figures indicate that a certain amount of measles antibody will pass from the gastrointestinal tract and bring about a definite passive immunity in some individuals.

Another evidence of the absorption of antibody from placental extract given by mouth is that 23 patients with a positive Dick test have been rendered Dick negative by placental extract so given. The duration of the negative stage has been variable but was as long as 18 days in 13 individuals. The importance of this procedure in the prevention of scarlet fever remains to be determined.

In addition to the evidence of antibodies shown by human experiments, there is also evidence from animal experiments that the extract contained diphtheria antitoxin, and an antibody against poliomyelitis. There is no need of discussing these antibodies here.

The method of preparing placental extract has not been sufficiently standardized to lead one to believe that the

most satisfactory method has been found. Various fractions have been made separating the placental extract into various globulins; but it does not appear as yet that these various fractions differ materially so far as their content of measles antibody is concerned. It has seemed that the nearer one stays to a whole extract, the more efficacious a given dose of the material will be for measles prophylaxis. On the other hand, the whole extracts are extremely difficult to filter. It is obviously desirable—if not essential—that the final product shall be passed through a Berkefeld filter to insure its sterility, and this process must be carried out even at the risk of losing a certain amount of antibody. It is much better to use a dose of 5 or 6 c.c. of material that has been filtered than to attempt to give unfiltered material in a dose of 2 or 3 c.c.

The only direct method of determining the potency of placental extract is to use each lot experimentally for its ability to prevent measles. Such indirect methods as the determination of diphtheria antitoxin content of the original material and of the fractions made are not satisfactory. The source of error here is that the diphtheria antitoxin is apparently segregated almost entirely in the pseudoglobulin fraction, but measles antibody is more generally distributed among all the globulins. There was an indication in the earlier part of the study that the nitrogen content of the extract was about as satisfactory as any other method. The figures for this have not been compiled on the later cases but it is known that the extracts with a higher nitrogen content are more effective than those that are too low. It is evident that a final satisfactory method of making the extract and of determining the proper dosages depends upon the solution of this fundamental problem of potency testing.

CONCLUSIONS

1. The use of placental extract in the prevention and modification of measles offers at the moment the best hope of giving us some control of this disease.

2. Placental extract appears to be more efficacious in these respects than convalescent serum; and convalescent

serum, in turn, is more efficacious than adult serum or whole blood.

NOTE: This study was supported in part by a grant from the Commonwealth Fund of New York.

Humanizing Knowledge

AT present so-called "serious" books, even when they pretend to be of a popular nature, are rarely written exclusively for the general reader. Scholars and men of science almost always write more or less unconsciously for one another. This is a natural outcome of their training. They must prove their preparation to deal with the subject in hand. They cannot forget their fellow workers in the field, and properly wish to enjoy the reputation of scientists and scholars and not that of mere popularizers. They are so accustomed to technical terms that they use them without

realizing how few of their readers can be expected to understand them. This is the result not of a love of pedantic display but an acceptance of the rules of the game as they have been taught it. . . . There is a heavy prejudice in learned circles against the popularizer. Those who are disinclined, or mayhap unable, to write plainly and pleasantly for the layman, are prone to denounce all attempts to popularize knowledge as vain or as mere expedients to keep the pot boiling.—James Harvey Robinson, *The Humanizing of Knowledge*, 1924.

Recent Experiences in Scarlet Fever Control*

JOHN P. KOEHLER, M.D., F.A.P.H.A.

Commissioner of Health, Milwaukee, Wis.

THIS paper is being presented not so much because the writer has any new scarlet fever control measures to offer, but rather for the purpose of reporting certain experiences following the extensive use of well known control measures during a scarlet fever epidemic in Milwaukee. Even most of the experiences recorded herein are not new, but very similar to those reported by others.

It is necessary for me to limit this report almost entirely to statistics, personal observations, and conclusions, without describing procedures in detail or presenting all reasons for conclusions.

The scarlet fever epidemic began in January, 1934; abated temporarily during the latter half of July; recrudesced rapidly in September; and reached its peak for the year in October with 1,041 new cases reported.

The 1935 peak was in January, when 1,407 new cases were reported, which number might have been exceeded in February if additional control measures had not been taken. During 1934 there were 5,964 cases of scarlet fever reported with 20 deaths. During the first 6 months of 1935 there were 4,541 cases and 24 deaths reported.

When it became apparent during the early months of 1934 that Milwaukee

was to be visited by one of its periodic scarlet fever epidemics, immediate and serious consideration was given to all the available scarlet fever control measures.

IMMUNIZATION

After a thorough discussion of immunization with various committees of the County Medical Society, the Health Department with the approval of the County Medical Society, decided to immunize children in highly infected schools.

Dick testing to discover the susceptibles was immediately started in 12 public and parochial schools with an enrollment of approximately 10,000. The positive reactors were started with the 5 doses of toxin recommended by the Dicks: 500, 2,000, 8,000, 25,000 and 80,000 skin test doses at weekly intervals. Immunization was also offered by many private physicians as well as by the various Health Department clinics. Dick tests only were given to children in 7 additional schools and all reactors were referred to the family physician or Health Department clinics. As the disease spread, immunization was started in 6 additional schools, with an enrollment of approximately 5,000.

The work was started in 12 schools in March, 1934. The 6 additional schools were Dick tested and immunized during May, 1934. In October, 1934, 3 additional schools with an en-

* Read before the Health Officers Section of the American Public Health Association at the Sixty-fourth Annual Meeting in Milwaukee, Wis., October 7, 1935.

rollment of 2,240 were immunized. Seventeen thousand, five hundred preliminary Dick tests were made in schools and Health Department clinics, of which approximately 66 per cent were positive and 34 per cent were negative. Approximately 6,000 out of 9,000 children who started immunization completed the 5 doses. Re-Dicks of approximately 5,700 children receiving 5 doses of Dick toxin, gave 93½ per cent negative and 6½ per cent positive reactions. A 6th injection was given to approximately 200 children who had shown a positive re-Dick.

Since immunization against scarlet fever on a large scale was a new procedure in Milwaukee, it was deemed advisable to take the following precautions:

1. Every child was given a medical inspection before it was given its first dose of scarlet fever toxin. Children with chorea, rheumatism, heart disease, asthma, eczema, and other allergic ailments, were not immunized.

2. Every child had its temperature taken before each dose of toxin in order to exclude those that might be ill. At first a temperature of 99.6° was the maximum permissible, but this temperature was so common among the children that the maximum was soon raised to 100° F.

3. Whenever possible, all immunization work in schools was done in the afternoon. Some children immunized during the forenoon vomited during the afternoon and upset the entire classroom.

4. When immunization treatments were given in the morning, the school nurse remained at the school during the afternoon.

5. A nurse and doctor were on duty in school on the day following immunization for the purpose of inspecting rashes and other signs of reactions.

6. Printed notices were given to parents at the time of the first injection advising them of some of the reactions that might occur and assuring them that there would be no cause for alarm.

7. Every child absent from school following an immunization treatment was visited by the school nurse.

8. Since all children, no matter how severe the reactions, made a complete recovery, it was finally decided not to have the nurse

follow up such cases in the homes. Whenever possible, school immunization clinics were conducted on a Friday afternoon to reduce school interference to a minimum.

REACTIONS

By interviewing pupils, teachers, and parents, nurses, obtained as much information concerning reactions as possible. Reactions were classified as: severe systemic, moderate systemic, mild systemic and local reactions. Children with a temperature of 102°, prostration, vomiting, and diarrhea were reported as having severe reactions; those with lassitude, a noticeable rise in temperature, some nausea and vomiting, rash, and muscular pains, as having moderate reactions; and those with a rash and a slight rise in temperature, as having mild reactions. Local reactions consisted of redness and swelling of the arm and some local pain.

According to this classification, the average percentage of reactions for the 5 doses is as follows: severe systemic 3 per cent, moderate 15 per cent, mild 16 per cent, local reactions 23 per cent, and no reactions 43 per cent. The 3rd and 4th injections were followed by the most severe reactions. Two or three children who received the larger doses of toxin by mistake, showed no unusual reactions. All children recovered completely from all reactions, and most of them within 24 hours. About 20 per cent of the children developed a rash after the 2nd, 3rd or 4th injections.

Parents as a rule did not worry about reactions when forewarned. Health departments and physicians who have not the confidence of parents, will find it more difficult to immunize children against scarlet fever on account of the many severe reactions.

RESULTS

The immunization of 6,000 children in a city of over 600,000 population

cannot be expected to check a city-wide scarlet fever epidemic, although such immunizations did not slow up the epidemic temporarily. The immunization work immediately controlled scarlet fever in those schools in which a large percentage of children accepted immunization. The immunized schools were almost completely free from scarlet fever during the year 1934, after the 2nd injection of toxin. During 1935, scarlet fever again occurred in these immunized schools among the kindergarten and 1st grade children who did not attend school in 1934 when immunization was done.

Schools with an attendance of 14,286 children in which immunization was done, had 1,102 cases of scarlet fever from January 1, 1934, to July 1, 1935. Similar unimmunized schools with the same attendance had 1,550 cases during the same period.

Twenty-four cases of scarlet fever occurred among 800 children who had only 1 dose of Dick toxin—14 within the first week after the injection. Nine children of 600 who had 2 doses; 12 of 900 who had 3 doses; 2 of 740 who had 4 doses; and 14 out of approximately 6,000 receiving 5 doses of toxin, contracted scarlet fever. Thirteen of the 14 came down with scarlet fever several months after they had been immunized. Nine of the 14 were verified by Health Department diagnosticians. All of them had had negative re-Dicks. Thirty-six children with negative Dick tests and without immunization treatments contracted scarlet fever. Twenty-four of these contracted the disease 3 months after having had a negative Dick. The scarlet fever rate for completely immunized children is about 2.3 per 1,000, while the rate for the elementary school population of 87,000 is approximately 60 per 1,000.

It should also be mentioned that 5 of the 14 cases, among completely im-

munized children, were secondary cases in families. Children who were immunized against scarlet fever had approximately the same percentage of hemolytic streptococci carriers among them as did the non-immunized children. This percentage was 20 in the immunized children and 18.5 in the non-immunized—all in the same school-rooms.

Scarlet fever in children's institutions in the city as well as in the county of Milwaukee was effectively controlled by means of the Dick test and scarlet fever toxin. If the immunization program started in March, 1934, had been continued until all schools had been immunized, there is every reason for believing that the epidemic would have been controlled much sooner than it was. A larger immunization program in schools was not conducted due to lack of funds and lack of support on the part of a large percentage of family physicians.

NOSE AND THROAT CULTURES

Another procedure which the Milwaukee Health Department adopted during its campaign, was the culturing of noses and throats for hemolytic streptococci. All children in rooms that had more than 2 cases of scarlet fever reported within 1 week, were cultured. Later on, kindergarten and 1st grade rooms were cultured whenever 1 case of scarlet fever occurred. Children who were absent from school 3 or more days were visited by the nurse and cultured. Such absentees were isolated at home for 10 days if found to be carriers. Homes of carriers were not placarded but the Police Department assisted the Health Department most successfully in keeping carriers at home.

Approximately 6,000 children of 25,000 cultured, were found to be positive for hemolytic streptococci. Absentees averaged about 25 per cent

positive, while room cultures averaged 22 per cent. It is not easy to determine the value of this tremendous amount of culture work. After culturing for several weeks during the spring of 1934, it was decided that the exclusion from school-rooms of hemolytic streptococci carriers was not of sufficient value as a control measure to justify its continuance.

This decision was based on the fact that the number of new cases reported did not show any decrease. Almost immediately, however, when the procedure of culturing infected rooms was discontinued, the number of cases increased very rapidly. Children who were excluded from school as carriers show a scarlet fever rate of 19 per 1,000 for the 10 day exclusion period; children not excluded because negative for hemolytic streptococci have a scarlet fever rate of 21 per 1,000 for the 10 day period after their cultures were taken. This, of course, would lead one to believe that children with positive throats were less apt to come down with scarlet fever during the 10 day exclusion period than those with negative throats remaining in school.

Families having scarlet fever carriers, had a scarlet fever disease rate of 11 per 1,000 for other members of the family during the 10 day exclusion period, compared to 5 per 1,000 in families where the school children had negative throat cultures. It would seem, therefore, that the advantage, if any, of excluding scarlet fever carriers from the classroom is not in having them out of school while they are coming down with the disease, but rather to eliminate them for a 10 day period as carriers.

The percentage of negative and positive cultures not only seems to vary according to classes and schools, but also according to the nurse taking cultures. In taking cultures of former scarlet fever patients, individual nurses

varied from 5 to 60 per cent in obtaining positive cultures. The carriers in various groups of former scarlet fever patients are as follows: in the 90 per cent apparently in good health, 40 per cent; in the 20 per cent that had their tonsils removed, 40 per cent; in the 30 per cent that had congested throats and diseased tonsils, 46 per cent; in the 2.5 per cent apparently in poor health, 55 per cent.

In spite of the questionable value of culture taking as a scarlet fever control measure, the Health Department decided to culture infected rooms again when the disease seemed to be beyond control, in January, 1935. After culturing rooms for several weeks and excluding all carriers, a very slow gradual decrease of cases was noticeable. However, the improvement was not sufficient to inspire much confidence in the procedure. My personal opinion is that a certain number of exposures are prevented through the isolation of hemolytic streptococci carriers, and during an epidemic such a procedure is justifiable even though it is very time consuming. Due to the tremendous number of hemolytic streptococci cultures examined, including the preparation of media and other necessary supplies, it was not possible with the available staff to determine the specificity of the hemolytic streptococci, by serologic, biochemical, or toxicogenic reactions.

QUARANTINE

The value of quarantine during a scarlet fever epidemic in a large community is becoming more questionable every year. I am wondering whether absolute quarantine of entire families for scarlet fever should not be put in a class with fumigation, in which the public and health officers had so much confidence a few years ago. No one will deny that quarantining of scarlet fever patients will prevent some ex-

posures, and at least delay some infections, but during an epidemic it is almost worthless, as far as tangible results go. The quarantining of entire families for several weeks is not only a great inconvenience, but also such a tremendous economic loss for health departments as well as the families, that I am beginning to wonder whether the results justify the effort and expense. The state law in Wisconsin requires that scarlet fever cases be quarantined at least 28 days from date of report. In November, 1934, the State Board of Health gave the Milwaukee Health Department permission to shorten this quarantine period to 21 days for mild cases having two consecutive negative nose and throat cultures. Since a large majority of the cases were very mild, it happened that approximately 70 per cent of all patients were eligible for 21 days release cultures; 32 per cent had negative cultures within 24 days, an additional 24 per cent in 28 days, 15 per cent were positive and 29 per cent were not cultured. This shortening of the quarantine period increased the capacity of the isolation hospital and in that way helped prevent additional cases in homes.

According to a special study, 56 secondary cases developed within 2 weeks after release from quarantine of 2,828 cases; 1,142 cases released in 3 weeks had 30 secondary cases, or 2.7 per cent; 1,457 cases released in 4 weeks had 19 secondary cases, or 1.3 per cent; 229 cases released in 5 weeks and over had 7 secondary cases, or 3 per cent. Quarantine regulations were enforced more rigidly than during normal times. Daily lists of quarantined families were sent to the Police Department who kept a very close watch on all such homes.

It is generally believed that quarantine during an epidemic is not so effective as it should be on account of there being too many undiagnosed and un-

reported cases that are responsible for the continuance of the epidemic. This is partly true, yet the undiscovered cases alone cannot account for many of the unusual experiences associated with scarlet fever. Scarlet fever is endemic in many communities and epidemic every few years. Such endemics and epidemics can only be explained on the basis that every large community has a high percentage of susceptibles as well as carriers. By means of the Dick test it is possible to determine the percentage of susceptibles in any community. By means of nose and throat cultures, we can, at least to some extent, determine the number of hemolytic streptococci carriers.

In culturing the noses and throats of former scarlet fever patients on 2 consecutive days, we found approximately 43 per cent positive for hemolytic streptococci. This percentage did not seem to vary much in patients who had been released from quarantine, 1, 2, 3, and 4 months previously. Forty-three per cent of carriers in former scarlet fever patients must be given some consideration regardless of whether we are dealing with a scarlet fever hemolytic streptococcus or some other strain.

It can readily be seen that very little is gained by quarantining a patient while acutely ill in bed for 3 or 4 weeks, and then releasing him when he is well enough again to mingle with the public, even though he may be just as infectious after his release as he was during quarantine. This high percentage of carriers among former scarlet fever patients accounts for many of the hitherto puzzling experiences. During the latter part of September, 1934, when scarlet fever started up like a conflagration, we were inclined to believe that many unreported cases during the summer months were responsible for this tremendous increase.

While we know that a few children

who had only recently had unreported scarlet fever probably did return to school, we also know that the number was not sufficient to account for the explosive outbreak soon after schools opened. The increase no doubt was due to the fact that there was still a large percentage of children susceptible, and hundreds who had had scarlet fever during the previous months were still carriers of virulent scarlet fever hemolytic streptococci.

This large percentage of carriers among former patients explains many secondary cases months after the original case occurred. This also accounts for the fact that health authorities find it difficult to agree upon the length of quarantine. It can readily be seen that if a large percentage of these patients are infectious for months after their acute illness, it does not make a great deal of difference whether they are released at the end of 2, 3, or 4 weeks. The only difference is that some exposures will be delayed a week or two longer, but not entirely prevented by quarantine. Releasing by cultures cannot be considered too satisfactory, although I believe that it is an aid in keeping in some carriers a week or two longer. Approximately 25 per cent of all patients who showed 2 consecutive negative cultures when released, again had positive cultures at least once during the following 5 months. Only 15 per cent of positive cultures changed to negative within 5 months after the patient was released from quarantine.

While I realize that most of the statistics based on cultures for scarlet fever hemolytic streptococci are of questionable value, nevertheless, when such statistics fit into our epidemiological experiences, we should not hesitate to give them consideration.

CLOSING OF SCHOOL-ROOMS
In spite of the Health Department's

efforts to control the epidemic with immunization, culturing, and quarantining, it became more threatening every day. The situation appeared so critical that only drastic action could prevent the loss of many lives. Scarlet fever cases were being reported at the rate of approximately 300 per week, and measles had reached 600 per week. Several children had died with a combination of scarlet fever and measles.

After a conference with representatives of schools, churches, theatres, the Association of Commerce, and the medical profession, it was decided to isolate all children under 7 years of age in their homes for 4 weeks. This was later extended to 6 weeks.

The reasons for isolating this age group are obvious, and I will not take time to mention them. The order of the Health Department excluding children under 7 years of age from schools, churches, theatres, Sunday schools, and all other public places, with the exception of stores when accompanied by parents, went into effect February 18, 1935. Some of the more important results obtained are as follows:

1. Scarlet fever, measles, German measles, and chicken pox continued to increase for the length of their incubation periods, namely, 1 week for scarlet fever and 2 weeks and slightly over for measles, German measles, and chicken pox. This proved that very few cases, if any, were unreported as soon as these children left school. Parents were scarlet fever minded and very few of them failed to call a doctor when the younger children showed signs of illness.

2. The percentage of scarlet fever in children under 7 years gradually dropped from 34 to 18 of the total cases reported. This low percentage continued several weeks after the children again returned to school, but gradually went up to its normal by the time schools closed in June. Forty per cent of scarlet fever in the isolated children could definitely be traced to other scarlet fever patients, over 7 years of age, in the home.

3. The total number of new scarlet fever cases reported began to decrease toward the

end of the first week of the ban and continued to decrease quite rapidly from 300 per week to 51 at the end of the school year.

4. Measles, like scarlet fever, showed a large total decrease at the end of the incubation period and also a large percentage decrease in children under 7 years of age. The decrease in rubella was not quite so spectacular as that in measles because this is a much more common disease among adults than is measles.

Chicken pox, which was very low when the ban went into effect, decreased to an insignificant number. The decrease in scarlet fever, measles, German measles, and chicken pox during this isolation period was not general throughout the state or in communities near Milwaukee. While these diseases decreased in Milwaukee, they were increasing throughout the state. Some of the smaller communities reported more measles and chicken pox in their weekly reports to the State Board of Health than did the City of Milwaukee.

5. At the end of 6 weeks, when approximately 20,000 children under 7 years of age returned to school, there was no significant increase in cases of the diseases mentioned before. Had some cases been covered up, the opening of schools would have uncovered them. Three weeks after the children returned to school, measles, German measles, and chicken pox began to show an increase. During February, 1,569 cases of measles were reported; 1,159 in March, 914 in April, 1,475 in May, and 2,046 in June. Ordinarily during an epidemic the peak in measles is in April. This year it occurred in June. By postponing measles in hundreds of children until warmer weather appeared, it is probable that some lives were saved.

During the first 3 months of the year, there were 3,500 cases of measles with 5 deaths. Since that time up to July 1, there have been reported over 4,400 cases with only 2 deaths. While the closing of an entire school system in a community may be neither practical nor effective, nevertheless, there is no doubt in my mind about the practicability and effectiveness of isolating children under 7 years of age during a serious epidemic. By taking almost 25 per cent of the elementary school population and almost 50 per cent of the total child population effec-

tively out of circulation, any community can at least temporarily check epidemics of childhood diseases.

Children under 7 years of age are the most susceptible and the most exposed to contagious disease. They are the foci of most epidemics. It must not be forgotten, however, that the isolation of children under 7 years of age must be carried out just as intelligently and scientifically as any other epidemiological procedure. To obtain satisfactory results, children must be isolated for at least 1 month and preferably 6 weeks to 2 months.

School and health authorities have so many times stated that schools with medical and nursing supervision are the safest places in the world for children, that they are apt to believe it regardless of what may happen to the children during an epidemic. There is nothing gained by assuming that nurses and doctors can pick out all scarlet fever cases and carriers by daily or weekly classroom inspections or home visits, when we know that this can only be done when children have perceptible signs or symptoms of the disease.

CONCLUSIONS

1. Immunization against scarlet fever with 5 doses of Dick scarlet fever toxin, is both effective and safe. Even children having only 2 doses had a case rate of 15 per 1,000 compared to 60 per 1,000 for the unimmunized school children. Fear of reactions no longer justifies the opposition of private physicians and health departments to scarlet fever immunization.

2. Nose and throat cultures for the control of scarlet fever carriers may prevent some exposures and infections, in spite of the many uncertainties of this procedure.

3. Strict quarantine of scarlet fever patients prevents neither epidemics nor epidemics, because too many patients remain carriers after release from quarantine. An absolute quarantine of entire families is probably responsible for more additional cases than the proper isolation and quarantine of only the patient. Scarlet fever quarantine is based more on tradition and expediency than on scientific facts.

4. The strict isolation of all children under 7 years of age for 6 weeks during a scarlet fever epidemic not only reduces the number of scarlet fever cases, but also aids in the control of other childhood contagious diseases. The permanency of this improvement depends upon the percentage of immunes produced by the epidemic and immunization.

Public health officials have reason to point with pride to achievements in typhoid fever,

smallpox, and diphtheria control, but when it comes to the control of scarlet fever, they have been too easily satisfied with large and attractive isolation hospitals and the annual imprisonment for a period of 3 to 6 weeks of thousands of our most law abiding families.

More money for immunization and less for contagious disease hospitals should be the slogan of all progressive health departments.

The Will Rogers Memorial Fund

THE press has carried the report that, among thousands of suggestions made by contributors to the Will Rogers Memorial Fund, more persons have suggested that a hospital be founded in his memory than any other plan. Among the suggestions sent to the trustees is that for a well rounded health center which might conceivably represent the fine human qualities of Will Rogers fully as well as any hospital. Through a health center people might be kept well enough to enjoy fully the wit and humor for which he was so noted.

Would it not be a desirable direction in which to attract public interest if health workers everywhere in making contributions to this fund would pass along the suggestion for some activity related to the health program, such as this health center?

DR. PARK IS AWARDED THE ROOSEVELT MEDAL

IT is not medals, or public episodes of recognition which give distinction to such persons as Dr. William H. Park, but the enduring appreciation they have won from their professional colleagues. And yet there is for all of us a glow of confidence in the essential rightness of matters in our contemporary life when such a physician is singled out from the many contributors to science for the honor of the Roosevelt award on October 27, the 77th anniversary of the birth of Theodore Roosevelt.

Embryo-laryngologist, microscopist, bacteriologist, sanitarian, medical educator, publicist, teacher of a long succession of health commissioners, crusader for child life, consulted by half the world, and held in affectionate regard by every physician so fortunate as to know him, Dr. Park has earned any and all distinctions which may come to him.

The medical literature of almost a half century contains the record of observations, experiment, lessons learned and taught, in the career of Dr. Park, and it would be a superfluous indulgence to select and name the steps in progress toward complete knowledge to be read in the titles of fundamental and supplementary contributions from his hand.

This gentleman of science, a very perfect knight of bacteriology, belongs to that choice company so ably conceived by the late Arthur Little as a "fifth estate, composed of those having the simplicity to wonder, the ability to question, the power to generalize, the capacity to apply; in short, the company of thinkers, workers, expounders and practitioners upon which the world is absolutely dependent for the preservation and advancement of that organized knowledge which we call science."

The simple directness of method, the clarity and utter frankness of report, the invariable readiness to listen to objections, to accept evidence, to be more

than generous to the work of others, to bring forth the creditable work of associates, all have combined in his scientific manner to make Dr. Park's presentation of a report or his participation in a discussion an occasion as refreshing as it is always enlightening, a true intellectual exhilaration, giving confidence in the continuing value of the professional platform as the tournament half of medical progress.

To those concerned in the social application of medical discoveries and the useful established facts of biological and medical knowledge through the instrument of civil government at tax payers' expense, Dr. Park's contribution in maintaining the first and most eminent municipal laboratory of diagnosis and research for 42 years free from the malign influences of political corruption and technical deterioration, is almost as stately a monument to his quality as citizen and director as have been his mastery of preventable diseases.

It has been not only through the good fortune of circumstances but as a result of the application of a consistent and sustained philosophy of study, controlled observation, experiment in test-tube, animal cage, institutions, and the homes of the city, that Dr. Park has found in his own hands and created to meet each probable need that entire and complete series of resources upon which progress from theory to practice, from hope of life saving to tangible proof of its successful accomplishment are based.

If it were not enough to have added generously to the extent and precision of human understanding of the specific causes and associated factors concerned with the prevalence of communicable diseases, and to have carried to unbelievable success the mass application of specific measures for their wholesale prevention and control, and to have built an enduring structure of precedence and procedure for the administrative officers of health in all lands to intimate and add to, his position as teacher, as trainer of other directors of laboratories or searchers in the border-line of knowledge, as demonstrator to practitioners in medicine in a thousand communities of the way to carry new skills of diagnosis and immunity into the homes of the nation, would still be eminent and of high degree.

If and when retirement from service to his city be demanded by the exigencies of municipal ordinance, Dr. Park will continue in his position as leader in the science and art of public health, held in admiration and affection by the entire membership of the American Public Health Association.

FIFTEEN YEARS OF ADMINISTRATIVE HEALTH PROGRESS

A MILESTONE in public health progress was the appointment by the American Public Health Association in 1920 of a Committee on Municipal Health Department Practice, since 1925 known as the Committee on Administrative Practice. This committee was charged with the "preparation, study, standardization, and presentation of scientific public health procedures, by the collection of information in regard to current administrative health practice, the analysis of the material obtained to derive standards of organization and achievement and the translation of these standards into terms of concrete achievement through an information and field service."

Fifteen years ago there was a striking lack of authentic information in regard to the practice of health departments. A health officer may now review his problems and program in the light of experience in other communities and apply

PUBLIC HEALTH EDUCATION*

Why Not in November Issue?—This section failed to appear in the November, 1935, issue because no copy had been prepared during the week preceding the Milwaukee meeting.

Health Education Fared Well at Milwaukee—We had space for Health Education Headquarters such as we have had only at Pasadena. . . . Section meetings were well attended . . . with some good material presented for publication in the *Journal*. The Institute drew another new group many of whom were new to the Annual Meeting. The annual session of the Section gave thoughtful consideration to several important matters. Several staff members of Milwaukee Health Department rendered much faithful and effective service in connection with Health Education Headquarters. . . . Everything was lovely except the meeting rooms in the Auditorium which distorted voices and made much of the talk practically unintelligible.

Headquarters Program at Milwaukee—An experiment this year was a program of demonstrations. Included were electrical transcriptions of radio plays, presented by T. C. Stowell, of New York State Dept. of Health.

Scientific and popular 16 mm. motion pictures received from various sources were projected by Eastman Kodak Stores of Milwaukee. "Contacts," a talkie from Hennepin County Tuberculosis Assn., Minneapolis, was put on one day.

The new A.M.A. dramatic broadcast was received on Tuesday afternoon.

Slidefilms from the Society for Visual Education were shown daily.

However, the program was not a success because the attendance at Health Education Headquarters was scattered too widely throughout the day to secure satisfactory audiences for program events.

Education Headquarters at Milwaukee—The collection of classified portfolios was supplied by Social Work Publicity Council, 130 East 22d St., New York, N. Y.

In response to the invitation mailed to A.P.H.A. members a variety of additional material was received for display. Among those represented:

Health Service of Canadian Medical Assn. New York State Dept. of Health. International Society for Crippled Children. Bureau of Dental Hygiene of University of Iowa. Milbank Memorial Fund. Baltimore Health Dept. Milwaukee Health Dept. American Social Hygiene Assn. National Health Council. American Physical Education Assn. Buffalo Museum of Science. American Medical Assn. Massachusetts Dept. of Public Health. National Organization for Public Health Nursing. New Mexico Bureau of Public Health. Foreign Policy Assn. Cattaraugus County School Health Service. Nassau County Tuberculosis and Public Health Dept. Brookline Health Dept. Physical Education Health and Recreation Digest. Good Teeth for Children Council. *National Parent Teacher Magazine*. Wisconsin Anti-Tuberculosis Assn. Westinghouse Electric and Mfg. Co. Evaporated Milk Institute. Dairymen's League. Pictorial Statistics, Inc.

Scientific Exhibits at Milwaukee—The *News Letter* has taken the

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

story to all A.P.H.A. members, but these paragraphs are added to complete the record.

Due to the faithful persistence of Chairman Homer N. Calver, the Scientific Exhibits have grown in number, variety, and significance.

This year judges Hiscock, Connolly, and Norton gave citations of merit to certain displays for specified features which seemed to call for special mention.

Again Too Many for True Teaching—With an average session attendance of 125 to 140, the Health Education Institute was too large for effective teaching purposes. But there was one splendid gain. Announced as being for rural and small city workers it was the most homogeneous group yet gathered for the Health Education Institute.

Why not in 1936 experiment in having two or more institutes for specialized groups? Various state conferences of social work conduct from six to a dozen or more institutes. In most states only 25 may be enrolled. If more wish to enter a certain institute an additional leader is secured and another group of 25 is provided for.

How Do They Get That Way?—Again at Milwaukee half of those who turned up for the Health Education Institute had not registered in advance.

And, of course, every one suffered. Adequate planning was impossible.

Shall We Call It That Way?—Under "What Shall We Call It?" we submitted to our readers some of the "Definitions of Terms in Health Education" then under consideration by American Physical Education Association. (See *Journal*, for April, 1935, pp. 491-492.) Since then the report has been approved by A.P.E.A.

The committee of A.P.E.A. did an excellent piece of work. Probably after

careful examination we will find that the definitions and the accompanying interpretations and applications will fully serve the purposes of the Public Health Education Section.

The terms defined: health education, school health education, public health education, hygiene, sanitation, health, health instruction, health service, healthful school living, health examination.

Terms which have outgrown their usefulness: health supervision of school plant, health supervision of school processes, school hygiene, medical inspection, school health program, etc.

For a reprint of the full report address American Physical Education Association, 311 Maynard St., Ann Arbor, Mich. 5 cents.

Cutting House Organ Costs—*Alabama's Health* is published by Alabama Tuberculosis Association, Birmingham, Ala. It is sent to 200 Christmas Seal sale workers, health officers, local tuberculosis association presidents, etc.

The little magazine is reproduced by planography, one of the names given to offset printing, as explained under "Many Names for a Single Process," in the *Journal*, Sept., 1935, page 1045.

Acting Executive Secretary K. W. Grimley sends the following statement and will be glad to answer questions:

Copy is carefully typewritten with a heavy ribbon on sheets of paper slightly larger than the final size. (Any size original may be employed and the typewriting reduced to any desired extent.) Headings are typewritten with the same typewriter employed for the body type. These heads are then enlarged by photostat to an appropriate size, cut and pasted in place on the final typewritten draft sent to the publisher. Likewise illustrations are cut and pasted on the final copy. This final copy when completed is sent to the publisher and photographed, the photograph being the basis of the reproduction process. Pages are delivered to us flat and are hand folded and gathered by us.

The total cost of each of our issues is about \$15; approximately one-quarter the equivalent cost of printing. Any typewritten or printed material may be used in the process. Original photographs however must be screened before use; an operation which entails an expenditure of about one-half the cost of equivalent engraving. All our illustrations are clipped from magazines and circulars and are reproduced without any additional charge.

Municipal Broadcasting Station Not Afraid—The National Society for the Prevention of Blindness, 50 W. 50th St., New York, N. Y., reports a radio talk on "Foresight Saves Eyesight" in which syphilis was discussed.

Speaking over Station WNYC, New York municipally owned station, C. Edith Kerby of the National Society staff said:

Probably the most serious of all infectious diseases which may result in blindness is syphilis. This disease can affect the eyes in ways too numerous to be described here, except to say that every one of them is serious. Unlike any of the other infectious diseases, it can even be passed on to a baby before it is born, so that the child may come into the world with seriously defective or blind eyes, or it may apparently be healthy but carry in its system the germs which will attack its eyes several years later.

The method of diagnosing this disease by means of a blood test should be more generally used by physicians, since many of its victims may not be aware that they have syphilis or have been exposed to it. For the prevention of much unnecessary blindness and other defects in children, the National Society for the Prevention of Blindness urges the use of a routine blood test for all pregnant women to discover and treat mothers who need treatment.

How New Ideas Grow—Without benefit of psychological terms a business man outlines the process of growing ideas. Here are the five steps:

1. Formulate your objective.
2. Think in simple terms.
3. Be intelligently ignorant.
4. Discipline imagination.
5. Stop thinking.

The very first one is not as simple

as it reads. Much health education may be undertaken without an objective, much less one that is clear-cut and shaped to the plans under way.

Says the author:

The next step is the hardest. If you don't believe it, try to speak in clear, concise, simple words. Listen to others. Successful men have learned to think in fundamentals. It is at least a partial explanation of their success. It should be possible to reduce the most complex problem to simple terms. If it isn't, facts are lacking.

The third step implies a willingness, or better, an eagerness to learn. It is not difficult to feel that one "knows all about" one's organization, the people to be reached, the technics of the job, and so on. Eagerness to learn goes hand in hand with skill in learning. The writer says:

. . . intelligent ignorance confines questions to the problem at hand. At the same time it includes the simple "what, why, and when," for nothing is taken for granted.

To discipline the imagination is to avoid "danger ahead."

As one learns to think in terms of fundamentals, and as intelligence is used in satisfying curiosity, imagination begins to work. Immature or false conclusions are the dangers to be avoided at this point. Beware of flying too far from an earthy sense of values. . . . A new way of reaching a goal is not necessarily important. Neither is an old method necessarily sound. Imagination must not be allowed to lose sight of facts or fundamentals.

And now, most difficult of all is the stop thinking step. Give your mind a chance to work for you. Drop the subject. Lay aside the manuscript. Do other work, or read or play. When you get back to your problem the idea is likely to come, and it is likely to be a sounder proposition than if there had been no interval. In "New Ideas and How They Grow," by C. S. Kauffman. *Advertising and Selling*, 9 East 38th St., New York, N. Y. Nov. 7, 1935. 15 cents.

Lay Education against Cancer—

A large part of the annual report of the American Society for the Control of Cancer is devoted to professional and lay education. The Society has been making wide use of wax models, charts, and film strips. As many as 90 copies of film strip have been made.

Lay education, both direct and through numerous coöperating groups, has been widespread. The society supplies newspaper material and radio talks for local use.

An important development is the addition to the staff of Mrs. Carl B. Illig, Jr., for field work. Mrs. Illig has served as chairman of the Committee on Hygiene and Public Health of the General Federation of Women's Clubs.

In *Bulletin*, American Society for the Control of Cancer, 1250 6th Ave., New York, N. Y., Oct., 1935.

What Should an Assistant in Health Education Know?—A precedent has been set (at least, so far as we know it is a precedent) in a recent civil service examination in New York City, for an assistant in health education (publicity worker). The examination sheet brackets "publicity worker" in just this way.

We print below the 4 questions which the applicants were asked in the written examination. Question 3 relates to a one-page article on rickets which was supplied.

1. Choose one of the following health problems—

- (1) Prevention of cancer
- (2) Prevention of tuberculosis
- (3) Prevention of malnutrition

which you believe to be of importance in one of the following districts in New York City which you select and locate

- (1) A district populated largely by colored people
- (2) A district populated largely by people of foreign birth
- (3) A district populated largely by the "white collar" class

(a) Tell why you believe the people in the district selected should be informed concerning the problem chosen.

(b) What agencies and associations (national and local), because of their special knowledge or interest in the problem, might be helpful to the department in planning an educational campaign in the district?

(c) Mention some local agencies or organized groups in the district through which the health department might wish to work in order to reach the people with educational materials and ideas. (Exact legal titles are not required.)

(d) List and number the important basic facts about the problem you would wish to convey to the people of the district.

(e) What action would you wish the people to take with regard to the problem?

(f) What incentives or persuasive suggestions would you employ to get people to take the desired action?

(g) What publicity and educational media or other channels of reaching people would you use, assuming that the budget for this purpose is limited but not stinted?

2. To carry out certain health protective procedures for children, it is necessary to secure the consent of the parents. Among these are

- (1) Consent to remove child's clothing to make a physical examination in school
- (2) Consent to make a tuberculin test
- (3) Consent to administer toxin-anti-toxin or toxoid

Select one of these consents for consideration.

(a) Mention the objections to it commonly raised by parents.

(b) Frame answers to these objections.

(c) In a community where the procedure you selected is to be introduced, what would you suggest be done in advance to secure a high percentage of consents?

(d) A mother has written the health department that her medical advisor, who is an osteopath, has advised against the procedure. She is foreign born, but understands simple English. Write a short letter in answer to hers.

3. Using the article on Rickets as a basis and supplementing it by your own knowledge, write a 500 word first-draft manuscript entitled "Rickets. What It Is and How to Prevent It."

The article should be suitable for publication in booklet form and is intended for distribution to mothers of medium intelligence.

4. Assume that a rumor that poliomyelitis threatens the city is disturbing people, that

THE MACHINE AGE IN MAN

it is true that a few more cases than usual have been reported in the past month, but that, to the best knowledge of the health commissioner, there is no immediate threat of an epidemic. Assume also that the early symptoms of poliomyelitis are often vague or resemble those of some relatively harmless condition, that early diagnosis is advantageous both to patients and to the public, and that people have heard much about a certain curative serum the value of which has not yet been proved.

Write a 3 minute radio talk designed to allay needless fear and also telling people what precautions to take.

Syndicated Health Articles—"The Annual Directory of Features" appears in *Editor and Publisher*, Times Building, New York, N. Y., Sept. 28, 1935. 10 cents.

Health material appears under "The Debunker," "Family Doctor," "Health and Beauty," "Health Article," "Health Column" (Clendening), "Health" (Fishbein), "How's Your Health?" (Galdston), "Medical News" (Science Service), "Personal Health Service," "Secrets of Health and Success," "That Body of Yours," "Your Child's Health," "Your Good Health," "Your Health" (Copeland), "Your Weight and Your Height."

In addition to the above there are features on mental hygiene, child care, beauty, food, and psychiatry.

The Machine Age in Man—In Cabana Hall of Man, Buffalo Museum of Science, has been installed the "Human Factory," a three-dimension exhibit reproducing the well known diagram which came to us from Germany some years ago. The model is animated. Cogs move, wheels revolve, pumps operate, red and blue lights show the course of air.

This model represents, in terms of ordinary factory practice, the various operations essential to maintain life in a human being. The normal functions of the human body are directly comparable to the operations of a manufacturing plant. Certain raw materials

(food and air) are taken in, treated in order to serve a definite purpose. The only difference between the Human Factory and man-made factories is that the former uses all its products within the four walls of the body; a man-made factory ships its products for use elsewhere. In the cranium is located the office of the Human Factory. Here are the centers of judgment, intelligence, hearing, seeing, will power, motion, and feeling, corresponding to a factory's conferences to determine policies, telegraph department, mailing room where orders are received, department of production control, telephone switchboard which ties organization together. Processes in torso show what happens to raw material. This model was made in the Division of Preparation, Buffalo Museum of Science, under the direction of Dr. Carols E. Cummings, director.

Extent of Rural Health Service—A lot of state and local health workers should be able to make good promotional use of "Extent of Rural Health Service in the United States, Dec. 31, 1930-Dec. 31, 1934," in the *Public Health Reports*, Washington, D. C., Nov. 1, 1935.

Here are listed counties, townships and other districts directed by whole-time local health officers and maintained by local or state funds. A map and a diagram reinforce the lists.

What Actually Is Being Done?—We have heard rumors of federal funds being spent on health education. We have seen one very preliminary memorandum. But nothing more. Will any one in Washington or in any of the states help us to an intelligible statement for the readers of the *Journal*? Or suggest who can supply the necessary information?

Health Education in September, 1935, Journal—In "Sanitation in the Holy Land," by Mendelsohn (pages 997-998): descriptions of the first Palestine Health Week, and a Health Exhibition in 1924.

In "Sanitary Survey of Beverage

Establishments," by Mallmann and Devereux (top of page 1014): education of proprietors.

In "Books and Reports" see pages 1055, 1057, 1058, 1059, 1060.

"A Word to the Thrifty" (page 1067), plus diagram on the opposite page should interest many of our readers.

Health Education in October, 1935, Journal—"Health Information on the Air," by Blanchard (pages 1031-1088), reports a study of health education by radio, around San Francisco Bay. May suggest a project for other districts, for health councils or other groups.

"New Germany Teaches Her People," by Kleinschmidt (pages 1108-1113) (illustrated): tells of hygiene exposition; records some impressions; and raises some important questions.

"What Is Public Health?" by Hill (page 1134).

In "Books and Reports" (pages 1154-1162) are several reviews of interest.

Hygeia, October, 1935—Published by American Medical Association, 535 N. Dearborn St., Chicago, Ill. Here are selected items appearing in Oct., 1935, issue:

Prevention and treatment of goiter (first of three reproductions of radio talks). Caffeine and health (part 1). Care of contagious disease in the home. The physician in literature (books by and about physicians). Speech problems and speech care. Health of our navy at sea. The case of the man who exploded (a doctor's mystery). Health education through models (illustrations from Buffalo Museum of Science). Sir David Bruce (a pioneer scientist). Child guidance clinic. Some diabetes "cures" and "treatments." Surgical conditions in children (radio talk). This thing called dentistry. What about your child's feet? A modern Aladdin's lamp: how germs travel. Health news pictures. Books on health. Questions and answers.

In "School and Health":

Opportunities for health teaching in the curriculum. Health teaching in October. Solving health educational problems. Safety problems through the years in Boston public schools. Rest and nutrition class (Boston). Training for good posture. New health books for teachers and pupils.

BOOKS AND REPORTS

Preventive Medicine and Hygiene—
By Milton J. Rosnan. (6th ed.)
New York: Appleton-Century, 1935.
Price, \$10.00. 1,481 pages.

The 6th edition of this standard work has come to us with the statement that it is "extensively rewritten and entirely reset, much new material has been added and much dead wood deleted."

One misses familiar landmarks. In the Table of Contents we look in vain for Malta Fever, though fortunately it is still found in the index. The term Undulant Fever covers the many names under which the disease has been known.

Diseases are arranged in groups according to their general method of spread. This is good as far as it goes, but there is still a group of some 18 diseases (if snake poisoning can be considered a disease, as the author considers it) which are classified as "miscellaneous." Section II begins with venereal diseases and devotes chapters to sex hygiene, contraceptives, heredity, drug addiction and mental hygiene—certainly a mixture.

It is not until we reach the middle of the book that we come to Section V, which considers Public Health Principles and Practice, and the rest of the text is devoted largely to what is generally considered public hygiene—food, air, soil, water, etc.

Another change, which can hardly be considered an improvement from the reader's standpoint, is the moving of references to the end of sections instead of giving them at the foot of the page, as in the 5th edition.

We wish that the rewriting and deletion of dead wood had gone far

enough to remove the statement on page 16 that young bovine animals used for the production of vaccine must be examined to determine the absence of glanders. This blunder has appeared in edition after edition. On page 380, under the head of Glanders, the correct statement is made that cattle are immune to this disease.

The section on Tuberculosis is one of those mentioned as having been "largely reorganized." The discussion of the human and bovine varieties of the tubercle bacillus leaves much to be desired, and on page 31, the statement in regard to the comparative virulence of the two makes one wonder just what is meant.

On the whole, the book maintains the high standard set by former editions. It has grown almost too large to be used as an ordinary text, considering the time allotted in most medical schools to the teaching of hygiene. The book contains a wealth of information and will unquestionably maintain the position it has held through some 22 years as a standard reference. The printing and binding are excellent. MAZÏCK P. RAVENEL

Diet and Physical Efficiency—*By Howard W. Haggard, M.D., and Leon A. Greenberg, Ph.D. New Haven: Yale University Press, 1935.*
180 pp. Price, \$3.00.

This monograph attacks the fatigue question with strong emphasis upon a neglected viewpoint—nutrition. Quoting from the descriptive cover we read:

Howard W. Haggard and Leon A. Greenberg believe that the quantity and the quality of food have received a great deal of attention in recent years, but that the dis-

tribution of diet in time has not received the attention it deserves. This volume, therefore, is a study of the influence of the frequency of meals upon physical efficiency and industrial productivity. The attempt is made to discover and formulate the principle of the best mealtime interval, and the importance of this principle is emphasized by the fact that on the same amount of food the industrial output of factory operatives may be as much as 10 per cent greater under one mealtime arrangement than under another.

From studies first worked out in the laboratory, careful observations were made on 213 persons—children, students, clerks, and employees in a rubber factory. The contribution therefore is one of practical importance in everyday life as well as to industry and public welfare.

In addition to the theme of meal-times, diet and productivity, the 9 chapters take up nutrition, muscular efficiency, blood sugar, the respiratory quotient and its determination (as an index of efficiency), following which is a short appendix on the problem of industrial fatigue, and a bibliography of some length, also an index. The 35 tables and 31 figures have great instructional value and practically tell the tale in themselves.

Adapted as well to those not trained in physiology as to experts in nutrition, and indeed to general readers, the context is unusually clearly presented. Frequent repetitions have not detracted from the easily followed story, but, like the movie which shows up the hero, now from this point of view and now from that, the reader is charmed from cover to cover. Every possible question appears to have been foreseen and logically answered. For example, Why should we not eat candy or ice cream or take a soft drink for a "bracer" between meals? Like a novel, new characters appear as the chapters unfold, to be woven together with fine justice to each and all. It is indeed a romance in practical nutrition.

Naturally, diabetes and insulin come in for special attention. The most disturbing "villain" is the emotional factor. One "villain" seems to have been overlooked—stimulants substituted for food. Several other "intrinsic" ones such as physical impairment, degree of experience and skill, frequency of rest (or relaxation) and sleep, were probably connoted and ruled through controls, during the investigation. In a theoretical analysis of the possible elimination of fatigue made by the reviewer some years ago (Craig's *Diseases of Middle Life*, Vol. 1:88, 1923) he arrived at the conclusion that "if all the factors listed for the intrinsic causes of fatigue are properly supervised, it is only exceptionally possible to fatigue the human body by the extrinsic factors."

A reference oversight is that to the citation from "R" (C) P. McCord on pages 158-9 (including discussion), but the original may be found in McCord and Allen's *Industrial Hygiene for Engineers and Managers* (Harper's, 1931, p. 160). We note another omission from the Bibliography, viz., Amar's *Physiology of Industrial Organization*, 1919, and *The Human Motor*, 1921. Works on industrial efficiency and health have quite generally overlooked this undoubtedly important factor of *spacing meals*—even the late extensive 2 volume work, *Occupation and Health*, by the International Labour Office, while the old *Taylor Scientific Management* missed it completely, so that now one wonders whether the famous Schmidt in Taylor's experiment who increased his capacity of loading pig-iron from 12 to 47 tons per day did not do it more by piece-mealing than by "scientific management." Perhaps, too, the authors have explained the British supremacy—"three squares and two snacks each day"!

Finally, one is tempted to ask the

persistent question again: Is there a test for fatigue? Is not the answer, *the respiratory quotient*, as worked out by Haggard and Greenberg?

EMERY R. HAYHURST

Agents of Disease and Host Resistance, Including the Principles of Immunology, Bacteriology, Mycology, Protozoölogy, Parasitology and Virus Diseases—By Fredrick P. Gay and Associates. Springfield, Ill., and Baltimore, Md.: Charles C. Thomas, 1935. 1582 pp. Price, \$10.00.

The value of a comprehensive presentation of subject matter by one experienced student is admitted but it is felt that the rapid growth of Bacteriology makes it impossible for one individual to have first hand information regarding bacterial and other types of diseases. As the preface states, it is hoped that this book affords "a balance between the one-man text and the collected monographs of multiple authorities." It is believed that the close association and centralized interests of the participants have given the book a homogenous character which could not have been achieved by a widely separated group of writers.

The subject matter covers a much larger field than the usual text or reference book in Bacteriology. The chief author writes, "The 'Etiology of Disease' might be suggested as a simpler alternative title for this book." The varied contents reflect his conviction that the medical student should have presented to him "a larger background of disease causation, as well as a somewhat detailed consideration of the pathogenic bacteria, which although important, are by no means the only agents of disease," and he feels that the student will profit by viewing a "larger canvas depicting the entire range of disease causation,"—therefore the inclusion of material on disease producing

helminths, diseases of obscure etiology such as endocrine disturbances, epilepsy, etc.

The subject matter is divided into 12 parts. Part I serves as an introduction and presents the General Aspects of the Causation, Classification and Nature of Disease in an historical and philosophical fashion. Then follows a discussion of Inanimate Disease Agents and Tolerance. Chapters on Anaphylaxis and Allergy are given here instead of in the part dealing with Immunity, as is usual. Morphology and Physiology of the Living Disease Agents, ushered in by a chapter on the History of Bacteriology makes up Part III. Part IV deals with Infection in General, and Epidemiology. Part V is entitled "Resistance and Immunity" with a final chapter on Tissue Immunity.

Approximately one-third of the book is given over to the next part with the twenty chapters on "Pathogenic Bacteria and Diseases Produced by Them." The chapters on Streptococci and the Enteric Group of Bacteria, written by Dr. Gay, are especially complete. The remaining six parts discuss Spirochetes, Fungi, Viruses, Animal Pathogens, Diseases of Obscure Etiology, with a final group of chapters on "Practical Results in the Diagnosis, Prevention, and Cure of Infectious Diseases."

This final part discusses and appraises the various methods of disease diagnosis. No details of laboratory procedure are given,—the book is one "of principle rather than practice." The value of bacteriological and immunological tests used in diagnosis of infectious diseases is summarized in table form. This is one of many tables and charts given in the book. Some are reproduced from other texts; many are new. All add to the usefulness of the book.

Dr. Gay has entirely or partially written 23 of the 65 chapters, and Dr.

Jungleblut 10. Dr. McKinley is responsible for the entire section on Virus and Rickettsia Diseases.

The material is presented in a most interesting way and in an organized fashion which the experienced student will appreciate. The great number of contributions to the book do not interfere with the continuity of the material. In many cases, it is not necessary to see the signatures at the ends of the chapters to know the authors, but this adds interest.

It is printed on good paper and attractively gotten up, though its large size makes it a trifle unwieldy. The experienced student will be rewarded upon careful use of the vast amount of material with extensive references. One wonders if the undergraduate could make practical use of the book.

ANNA DEAN DULANEY

The Story of Medicine in the Middle Ages—By David Riesman, M.D. New York: Hoeber, 1935. 402 pp. Price, \$5.00.

The author has given us a most readable, interesting and scholarly history of medicine in the Middle Ages. He discusses the question of when the Middle Ages began and when they ended, and suggests that posterity may include us as having lived in the Middle Ages. This period is also spoken of as the Dark Ages. Singer says of it, "All theoretical knowledge was permitted to lapse; anatomy and physiology perished, prognosis was reduced to an absurd rule of thumb, medicine deteriorated into a collection of formulae punctuated by incantations; the scientific stream, its life-blood, was dried up at the source." The writer shows that from the period beginning with Gregory VII (1020-1085) there was definite progress in medical and surgical practice, and quotes Crump: "We need not praise, nor need we blame overmuch, but certainly we must under-

stand." In his Preface he says "The people who produced the Great Cathedrals, the French Chansons, the German Minnelieder, the Magna Charta, Parliamentary Government and above everything, the Universities, deserve our gratitude and admiration."

He sums up the advantages of the Middle Ages as being one dominant religion, one social system and one universal language. As there were comparatively few centers of learning, students centered at the points where learning was in evidence, first in the monastic schools, then the Cathedral schools, and finally in the great universities. The scholar in the Middle Ages was a distinguished man and learning was a mark of distinction. The doctor of medicine had a degree almost equal to a patent of nobility.

One of the things which we must be especially grateful to the Middle Ages is the preservation of literature due to the invention of printing. For 50 or 75 years after the invention of this art, printers were men of learning and spent their time in reproducing old texts, since there were few writers at the time. This resulted in the preservation of classical works which might otherwise have been lost. Many of the early medical books were textbooks for students and physicians written 200 or 300 years earlier. We owe then to the Middle Ages the preservation of the writings of the Greeks, Arabs, Romans and Jews, without which the progress of medicine and of culture would have been even slower than it was.

The chapters describing the rise of the universities in general and descriptions of special universities which follow are among the most interesting features of the book. These have been called "the greatest element in the emancipation of the human spirit," and if for no other reason than the founding of the universities, the Middle Ages are entitled to respect and gratitude. Rash-

dall is quoted as saying that they are "of greater and more imperishable value than its cathedrals." By the end of the Middle Ages some 80 universities had been founded in various parts of Europe. While many of these were short-lived, those of Paris, Montpellier, Bologna, Padua, Oxford, Cambridge, Vienna, Prague, Leipzig, Coimbra, Salamanca, Cracow and Louvain have existed down to the present day.

Even the confirmed student of history will lay this book aside with a warmer feeling toward the Dark Ages and a greater appreciation of what they did, in spite of their many failures and shortcomings. We cannot but feel that it is a distinct addition to our histories and written in a spirit of appreciation which will change the ideas of many concerning this period which has been almost damned by the title Dark Ages.

The book is excellently printed with few typographical errors, and is well indexed. The illustrations are fairly abundant and good.

MAZÏCK P. RAVENEL

Nutrition of Mother and Child—*By C. Ulysses Moore, M.D., M.Sc., (Ped.) Philadelphia: Lippincott, 1935. 258 pp. Price, \$2.00.*

The popularity of this attractive volume is attested by the 4th edition, which has been completely revised and rewritten. Considerable new material has been added on allergy, vitamins, the acid-base balance, mineral metabolism, and protein requirements. The book is written in non-technical style and is designed especially for mothers, nurses, and social workers.

Dr. Moore has been one of those most insistent upon the value of breast feeding in the face of refined methods of artificial feeding. His technic, *how to increase breast milk*, may be taken to be a standard method. It is described and illustrated thoroughly in this book. One wishes that Dr. Moore

had not insisted upon illustrating his breast-feeder tube, which is difficult to keep clean and of questionable value. It took years to get away from the old type of nursing bottle with a long rubber tube. Aside from this, mothers will find his clear-cut, understandable directions very helpful in supplementing directions given by a pediatrician or physician skilled in children's diseases.

RICHARD A. BOLT

Economic Problems of Medicine—

By A. C. Christie, M.S., M.D. New York: Macmillan, 1935. 242 pp. Price, \$2.00.

This is a very readable volume which discusses the subjects of medical ethics in relation to medical economics; medical education; private practice; the physician and the hospital; the physician in relation to medical organization and the community; workmen's compensation; health insurance; industrial medicine; the new methods of medical care now under trial or recommended by medical organizations; health insurance as a solution to the problem; and the essential elements in a comprehensive plan for medical care.

Deriving much from the reports of the Committee on the Costs of Medical Care, of which the author was a member and one of the signatories of the minority report, the endeavor is made to present the problem from the viewpoint of the private physician. To this source of material the author has added much new matter from foreign and American sources, the latter pertaining particularly to the Alameda County, Calif., Detroit, and Canadian plans, an approved industrial telephone company plan, and similar sources, as well as recent articles in the *Journal of the A.M.A.*

Undoubtedly the view presented is correct in that if the physician is to fulfil his whole duty to the community he must maintain a position of leader-

ship in all medical and health matters. He should not be blamed for the defective medical service so universally present today in America, which is an economic problem considerably beyond his control, but he should be treated fairly in any solution of the problem, including a wholesome recognition of the costs under which he performs his services. Things have gravitated to the present situation for many reasons, but a chief one is the bare subsistence level of a large proportion of the population.

For a reviewer, who is frank to acknowledge that he has a deeply social viewpoint, the subject seems very fairly presented and is a fine summary of facts, theories, and plausible solutions currently offered. Until, however, some means can be found to separate money from misery, as two distinct entities, and to consider the physician as essentially a disciple of humanitarianism, who, nevertheless, must find some adequate means of support and subvention in relation to the importance of the position which he plays in community and national welfare, the problem will continue to be mooted. The author holds that organized medicine can and must insure quality of service so that free choice of physician and confidential relationships may safely obtain, but, if so, it will have to be delegated much more authority than at present, both over its members and non-members, and here the responsibilities of the local medical society are duly stressed. The great problem of the patient's free choice of medical care or some other kind of care was probably not considered within the scope of the present volume.

Even the casual reader will be interested in the discussion on Health Insurance, and the final chapter, Essential Elements in a Comprehensive Plan for Medical Care. He will also be impressed with the great advantage we have in drawing upon the experiences

and mishaps of European schemes as well as the leadership in the solution of the economic problems of medicine which is appearing in various sections of our own country. The volume ends with quite an extensive bibliography and a brief index. It is the most convenient and recent assembly of the essential factors now at hand.

EMERY R. HAYHURST

Pediatric Treatment—By Philip S. Potter, A.B., M.D., F.A.A.P. New York: Macmillan, 1935. 578 pp. Price, \$5.00.

This book is just what its title indicates, a manual of pediatric treatment designed especially as a reference work for general practitioners. It is not written for specialists in children's diseases or in child hygiene. Very little space is given to etiology and pathology. The bulk of the book is composed of clear statements for treatment of the various diseases of infancy and childhood.

Dr. Potter has drawn largely from his own experience; but where standard procedures have been worked out by others, he has incorporated these and given exact references at the end of each chapter. The practical suggestions in the chapters on nutrition and infant feeding will be appreciated by the physicians struggling with difficult feeding cases.

The excellent arrangement of subject matter and typography of this manual, together with the complete index of authors and subjects, makes it a valuable volume for ready reference.

RICHARD A. BOLT

Work Relief in Germany — By Hertha Kraus, Ph.D. New York: Russell Sage Foundation, 1934. 93 pp. Price, \$.50.

This book presents a description of work relief in Germany prior to the recent political upheaval. The entire

work relief program was geared to meet the special and individual needs of the unemployed. Projects were developed and workers assigned to them for the primary purpose of preserving or restoring working capacity. The description of the special projects managed by the Work Relief Bureau clearly reveals this objective.

The work for wages plan in Germany was similar to that developed in the United States, except pay was based upon "the normal tariffs and wage agreements of the community" less 10 per cent, and the workers contributed to and were protected by state insurance for health, invalidity, unemployment, old age, and accident. Workers employed on work for relief basis, although ineligible for other forms of state insurance, were protected in case of accident.

"Shared work" was the term applied to the joint effort of government and industry to put men back to work. Selected private industries, taking workers from relief rolls, were subsidized upon their agreement to continue the employment of these workers for a specified time after the subsidy had expired.

Wages for all forms of work relief were paid in cash. The description of the function, organization, and procedure of the Work Relief Bureau is clear and concise. In view of the need for the development in the United States of a permanent public welfare program in which federal, state, and local governmental units will participate, Miss Kraus's discussion of the relation of the Work Relief Bureau to other public authorities is illuminating.

Although statistical and other supporting data are not presented, Miss Kraus, who for several years was the Director of Public Welfare in Cologne, Germany, writes with authority based upon intimate knowledge of the facts.

STOCKTON RAYMOND

Health Protection in the U.S.S.R.—

By N. A. Semashko. New York: Putnam, 1935. 172 pp. Price, \$1.75.

The author of this book was the first People's Commissar of Health, a post which he held for 12 years. He is therefore eminently fitted to write his side of the question. The book is frankly propaganda and belongs to the series called The New Soviet Library, being written by request.

The book outlines a more or less ideal administration of health, if one can believe in the method of operation now in vogue in Russia. Everything is under the Commissariat of Health, and the people are made to be good whether or not.

The book begins with a slap at the Tsarist régime and gives statistics of the deaths, child mortality, various epidemics, syphilis, etc., in that period. A glance at the Table of Contents shows that practically every subject pertaining to health and physical welfare is given consideration. The author says, "Thus unity in the organisation of the health service is the first distinguishing feature of Soviet medicine."

Among the striking features discussed is communal feeding. In 1931, 5 million workers and 3½ million office employees and peasants took their meals in public dining rooms, while 3 million school children were served hot lunches in school. The public dining rooms numbered 13,400, including 44 kitchen factories, which are described as "completely mechanised kitchens," each of which serves from 30,000 to 35,000 meals a day.

The book is interestingly written, but it is hard for us in this country to judge of its value, and we believe it will be a number of years before we can adequately judge of the success of the health program which the new government has inaugurated.

MAZÛCK P. RAVENEL

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

More on the Moot Subject of Poliomyelitis Vaccination—Infected monkey cord inactivated with formaldehyde was found to develop antibodies in experimental animals; then it was found safe for human administration. Large groups of children are being immunized and are being followed by controls.

BRODIE, M., and PARK, W. H. Active Immunization against Poliomyelitis. *J.A.M.A.* 105, 14:1089 (Oct. 5), 1935.

Kansas Dust and Health—Last summer's Mid-west dust storms which lasted for nearly 3 months increased morbidity and mortality from respiratory infections. There was no evidence that pathogenic microorganisms were carried by the dust.

BROWN, E. G., *et al.* Dust Storms and Their Possible Effect on Health. *Pub. Health Rep.* 50, 40:1369 (Oct. 4), 1935.

Emergency Training of Social Workers—Last year's training program of the Federal Emergency Relief Administration made it possible for states to secure for staff members training at accredited schools of social work. Suggestions for future programs were for longer study, better selection of students and need for choosing members for training on the basis of leadership ability.

BROWN, J. C. What We Have Learned about Emergency Training for Public Relief Administration. *The Family* 16, 6:172 (Oct.), 1935.

What Old and Young Sicken and Die of—Major causes of death are not

the most frequent causes of illness. The degenerative diseases top the former and the respiratory diseases the latter. Illness is most frequent under 5, least from 15 to 19. There are many other conclusions to be gleaned from this analysis of studies that have been reported in detail in earlier papers, another of which appears in *Public Health Reports* 50, 41:1404 (Oct. 11), 1935.

COLLINS, S. D. The Incidence and Causes of Illness at Specific Ages. *Milbank Quart.* 13, 4:320 (Oct.), 1935.

Tuberculosis and Climate—Factors which seem to influence tuberculosis death rates are: standard of education; risk of infection from negroes; life in dry, sunny, high climate. These are of more influence than per capita income and population density, according to a study of 150,000 deaths from 42 states.

COWLES, A., and CHAPMAN, E. N. A Statistical Study of Climate in Relation to Pulmonary Tuberculosis. *J. Am. Stat. Assn.* 30, 9:517 (Sept.), 1935.

All from a Sick Pig—Maine's first trichinosis epidemic enjoyed the distinction of being the largest reported. Of 71 persons known to have eaten the insufficiently cooked pork, 56 had symptoms. Twelve of those who escaped reacted positively to a skin test; all 25 showed eosinophilia.

DRAKE, E. H., *et al.* An Epidemic of Trichinosis in Maine. *J.A.M.A.* 105, 17:1340 (Oct. 26), 1935.

British Slum Clearance—In England it is usually the health officer who

instigates slum clearance schemes. What preparation he must have and how he should do the job are considered in this most interesting paper. One wonders how long it will be, if ever, before American health officials will be given similar powers and duties.

FAWCETT, H. A. *The Medical Officer's Practice of Housing.* Pub. Health 49, 1:6 (Oct.), 1935.

Mental Hygiene and Accident Prevention—Of all industrial accidents 85-90 per cent are said to have as their proximate causes the mental conditions of workers. This points to need for increased use of mental hygiene programs in industry. An analysis of what this involves by way of personnel and organization is given in detail.

GRANNIS, E. R. *Mental Hygiene as Applied to Industrial Accident Prevention.* Ment. Hyg. 19, 3:398 (July), 1935.

State Supervision of Industrial Health—Showing the need for industrial hygiene as a state health agency activity, the author points to the safeguards that should be thrown about this project.

GRAY, A. S. *Importance of Industrial Hygiene.* J.A.M.A. 105, 15:1158 (Oct. 12), 1935.

Professional Education of Nurses—Serious problems which confront nurses today are those of overproduction and under-education. Their direct cause is the apprenticeship system of education found in most schools of nursing. Responsibility for reform should be assumed by hospital authorities, officers of universities, the community, and the nursing profession.

HAWKINSON, N. X. *A Nurse's View of Nursing Education.* Mod. Hosp. 45, 3:67 (Sept.), 1935.

Thirty Dietary Substances—Very brief but inclusive is this summary of

the high lights of our knowledge in the field of nutrition.

McCOLLUM, E. V. *Food, Nutrition and Health.* Health & Phys. Ed. 6, 7:6 (Sept.), 1935.

Diphtheria Prophylaxis Experience—Observations covering 46,000 immunized school children indicate reduction of the expected incidence of diphtheria cases by more than 90 per cent. Immunity is greatest the year following treatment. Immunization of the majority reduces the rate among the non-immunized.

McKINNON, N. E., and Ross, M. A. *The Reduction of Diphtheria Following Three Doses of Toxoid.* J.A.M.A. 105, 17:1325 (Oct. 26), 1935.

Child Hygienists, Attention!—If regular hours of rest and conditions conducive to sleep are maintained, Nature can be trusted to see that the child gets enough rest. Experience in this nursery school belies the teaching of "authorities" who have insisted that, if a child does not fall asleep within a given time and sleep for a set period, someone is at fault. The findings should give relief to harassed parents.

REYNOLDS, M. M. *The Sleep of Young Children in a Twenty-four-Hour Nursery School.* Ment. Hyg. 19, 4:602 (Oct.), 1935.

About Abortions—In the group of women questioned, one-fifth of all pregnancies were terminated by illegal abortions, the per cent increasing as marriage lengthened. The practice has increased in recent years. Because abortion causes so many maternal deaths, this is a public health problem which cannot be ignored.

STIX, R. K. *A Study of Pregnancy Wastage.* Milbank Quart. 13, 4:347 (Oct.), 1935.

Every Community Needs a Mental Hygiene Program—That the mental hygiene clinic can develop a

community-wide program is well illustrated by description of the work done in Manchester, N. H.

STONE, S. What Mental Hygiene Means to a Community. *Ment. Hyg.* 19, 3:416 (July), 1935.

Bigger and Better Public Health—Public health as a concept needs broadening to include more than sanitation, epidemiology, and hygiene. The author visualizes a program covering economic security, housing, and medical care as well.

SYDENSTRICKER, E. The Changing Concept of Public Health. *Milbank Quart.* 13, 4:301 (Oct.), 1935.

Supreme Court Decisions about Milk—Reasonable licensing of milk producers and distributors, standards for dairy products, prevention of shipment of diseased cattle, and regulation of milk prices, all have been thoroughly established by a number of decisions of the U. S. Supreme Court.

TOBEY, J. A. Milk Control and the United States Supreme Court. *Pub. Health Rep.* 59, 40:1384 (Oct. 4), 1935.

ASSOCIATION NEWS

SCIENTIFIC EXHIBITS AT MILWAUKEE

IN the first few years of its existence, the Committee on Scientific Exhibits has avoided setting standards for exhibitions or requirements for participation beyond those necessary for expedient management. Although scientific exhibits for medical and other professional groups and public health exhibits for popular audiences have been common for many years, there was little experience to determine which types of exhibits were best suited to the particular type of professional audience found at American Public Health Association meetings. The policy of the committee therefore has been to accept nearly everything available from reputable sources within space limitations, and even to make an effort to get exhibits which were of general interest for any reason.

Its most outstanding contribution in this respect was the exhibit from the German Hygiene Museum, shown at the Pasadena meeting, for which credit is especially if not wholly due to Dr. W. W. Peter, who in behalf of the committee successfully concluded the preliminary negotiations with the German authorities, which made this showing possible.

Such remarkable contributions, however, can be expected only rarely. In the meantime it is evident that scientific exhibits are classifiable into two groups—those which are strictly scientific, that is, designed for the information and interest of professional people alone; and those which are examples of popular health education as used by official and unofficial health agencies. In addition, the exhibits in recent years

have included displays which were pictorial reports of work done, methods of organization, etc., of various types of health organizations, particularly health departments of hostess cities, counties, and states.

The scientific exhibit at Milwaukee exceeded all expectations, both as to size and number of exhibitors. There were 41 separate exhibits covering 10,000 square feet of floor space. Many of the exhibits related to laboratory interests due largely to the splendid efforts of the Laboratory Section Scientific Exhibits Committee, under the chairmanship of Dr. Fred O. Tonney. Milwaukee and the State of Wisconsin provided many valuable exhibits, assembled by Dr. W. J. Egan, chairman of the sub-committee on local exhibits. For the first time, citations of merit were awarded to certain exhibitors for excellence of one kind or another. The committee of judges in making these citations commented on these meritorious exhibits as follows:

Dr. M. Fernan-Nunez, Department of Pathology, Marquette University School of Medicine. *Title: Tropical Diseases in Milwaukee*—Unique and striking method of display, which stimulates interest and illustrates in a simple manner, the methods used to detect the diseases.

Department of Clinical Pathology, University of Wisconsin and State Board of Health of Wisconsin, Laboratory of Hygiene. Dr. W. D. Stovall, Dr. S. B. Pessin and Dr. Lois Almon. *Title: Monilias—Classification and Pathogenicity*—A complete presentation of the subject from the standpoint of the pathologist and mycologist, arranged in an attractive and interesting display in such a way as to give the non-technical observer an idea of the subject and to stimulate his interest.

Public Health Records—The Commonwealth Fund—Dr. W. F. Walker. Demonstrating a unit of public health service records—practical, simple—especially designed for health officers.

Traveling Health Exhibit—Wisconsin Anti-Tuberculosis Association. Dr. Hoyt Dearholt, Director. Effective Visual Exhibit, in drawing and holding attention—teaches that tuberculosis is a community health problem, and what may be done about it.

American Red Cross—Milwaukee County Chapter. Insignia of organization displayed so as to leave no doubt of its sponsor. Arresting figure of nurse who does the work with simple explanation of the two fields of endeavor covered, make up the body of the exhibit. Clear, forceful and simple.

American Medical Association, Chicago, Ill.
Title: What the Public Is Thinking About

Health and What the Medical Profession Is Doing About It—Exhibit aims to show questions asked by the public, and physicians' answers to them. Illuminated chart draws attention to question, and carefully displayed literature the answers. Fairly inexpensive, simple, arresting and convincing.

The increasing interest in scientific exhibits as an important part of the A.P.H.A. Annual Meetings promises well for the success of the scientific exhibits at New Orleans. Information concerning scientific exhibits at the next meeting in that city in the fall of 1936 may be secured by addressing the Committee of Scientific Exhibits, at the headquarters office of the Association.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

L. I. Burrows, M.D., East Central State Teachers College, Ada, Okla., College Physician
C. R. Fargher, M.D., Wenatchee, Wash., Health Officer
M. Flint Haralson, M.D., 424 State Office Bldg., Denver, Colo., Acting Secretary and Executive Officer, State Board of Health
Arthur E. Lien, M.D., Court House, Spokane, Wash., County Health Officer and Physician
William F. Lippitt, M.D., Box 362, San Juan, P. R., Chief, Bureau of General Inspection, Dept. of Health
Ezequiel Martinez Rivera, M.D., Box 128, Hato Rey, P. R., Chief of Public Health Unit
Joseph A. Yuskanish, 121 Allen St., Nesquehoning, Pa., County Health Officer

Laboratory Section

NEWS FROM THE FIELD

OCCUPATIONAL MORBIDITY AND MORTALITY STUDY

THE U. S. Public Health Service, in coöperation with the Works Progress Administration, has included in the national "health inventory" project (see editorial page 1370), a study, the object of which is the attainment of sickness and mortality rates in relation to occupation.

There is no doubt as to the need of this information for effective direction of national, state, and local programs of industrial hygiene and disease prevention in the adult population. From Census data it is estimated that the health of approximately 40 per cent of the total population is affected in varying degrees by their working environment. Thus among the 14 million persons employed in manufacturing and mechanical industries in 1930, more than 900 different occupational exposures to hazardous materials and conditions have been found. Many of these exposures undoubtedly affect health adversely. This supposition is substantiated by the finding of life insurance companies that the life expectancy of industrial workers is 6 to 7 years shorter than that of non-industrial workers. . . . It is the purpose of the Occupational Morbidity and Mortality Study to obtain sickness and death rates for each numerically important disease or disease group according to occupation. Sources of this information are the records of sick benefit associations and the records of personnel departments of companies having sick benefit societies. Information also is being obtained as to raw materials handled, the nature of the

end product of each process, and the working conditions surrounding each occupation. The schedule is so arranged that sickness and death rates can be computed for groups exposed to such specific potential health hazards as arsenic, lead, quartz dust, mercury, chromium, extreme temperature changes, dampness, etc. Thus, from a statistical analysis of the schedule, the effects of industrial exposures are measured in terms of occupational morbidity and mortality rates. It is expected that several hundred thousand of these schedules will be obtained by May 1, 1936.

It is anticipated that a number of interesting by-products will arise from this study: as, for example, the measurement of effects of marital status on health and longevity. The relatively high death rate usually recorded for single persons as compared with married persons frequently is ascribed to the factor of selection. Among persons physically able to engage in gainful pursuits, the selective factor may be expected to exert a relatively small influence, since invalids and persons having serious physical impairments would not be found in the population under consideration. Hence from this study the real effect, if any, of marital status upon health may be evaluated.

Information relating to the health of several hundred thousand persons engaged in a wide variety of occupations in about 35 basic industries will be accumulated and analyzed. Thus, from any viewpoint, the potential value of this survey to public health and general well-being in terms of dollars, health, and happiness is incalculable.

LAKE COUNTY, IND.

THE 1935 General Assembly of Indiana passed a law permitting the establishment of full-time county health units. The Lake County Commissioners on August 28, 1935, by resolution, set up the first full-time county health department in the state. The Commissioner of Health is Dr. William D. Weis, member A.P.H.A. In addition, provision was made for 1 sanitary inspector, 1 stenographer and clerk, and 4 public health nurses, all of whom will be employed as full-time workers after January 1, 1936.

NOBEL AWARD IN MEDICINE

THE Nobel prize in medicine was awarded to a German professor, Dr. Hans Speemann Frieburg of Breslau, October 24. The award carries with it about \$42,000.

N.O.P.H.N. APPOINTS DIRECTOR

DOROTHY DEMING, R.N., is the new General Director of the National Organization for Public Health Nursing. The Executive Committee made this appointment at the regular meeting on October 30.

Miss Deming has been a member of the N.O.P.H.N. staff since 1927 in the dual capacity of Assistant Director and editor of *Public Health Nursing*. She is familiar with every administrative detail and policy. This, added to her broad previous experience and her personal qualifications, assures unbroken continuance of the organization activities at a very important time in public health nursing development. Miss Deming will assume her new duties early in December.

NEW YORK HEART ASSOCIATION

A SCIENTIFIC Meeting of the New York Heart Association (Heart Committee of the New York Tuberculosis and Health Association) will be held at the New York Academy

of Medicine, December 3. Dr. Ernst P. Boas, Chairman of the Executive Committee, will preside over the meeting. Papers will be presented by Dr. Harold J. Stewart, Associate Professor of Medicine at Cornell University Medical College; and Dr. Archibald G. MacLeod, Associate, Hospital of the Rockefeller Institute.

RUSHWICK HEALTH CENTER OPENED

ON October 31, Mayor Fiorello H. LaGuardia of the City of New York dedicated the Bushwick District Health Center in Brooklyn. This Center is one of a series now operated by the Department of Health of the City of New York and is part of a project for new health centers being developed under Dr. John L. Rice, Commissioner of Health.

HEALTH OFFICERS FROM ABROAD

A STUDY tour of foreign medical officers of health, arranged by the Health Section of the League of Nations, began October 31 with the arrival in this country of seven health officers from foreign countries. Those who are participating in this interchange are:

Dr. L. S. Fridericia, Professor of Hygiene, University of Copenhagen

Dr. J. Parisot, Professor of Hygiene, University of Nancy

Prof. R. M. F. Picken, Welsh National School of Medicine, Cardiff

Dr. E. Rietz, Chief Medical Officer of Health, Stockholm

Dr. H. van der Kaa, Chief Health Inspector of the Netherlands, The Hague

Dr. B. Borcic, Chief of Health Service of Yugoslavia

Dr. Dela Johan, Secretary of State, Director of State Institute of Hungary, Budapest

The group was accompanied for a part of their itinerary by Dr. Frank C. Boudreau, Assistant Director of the Health Section of the League of Nations, Geneva. Dr. Boudreau has been the representative of the League

in making the arrangements for the study tour. The itinerary of this group included several days in Washington, a visit to Baltimore where the state and city health departments, as well as Johns Hopkins School of Hygiene were visited; thence the group went to Knoxville, Tenn., to see something of the medical and public health side of the work of the Tennessee Valley Authority. They will go to Chicago to study the work of the Chicago City Health Department. The remainder of their itinerary will include Detroit, Mich., Albany, N. Y., in connection with the work of State Health Department of New York; Boston, Mass., New Haven, Conn., and New York City.

JACKSON COUNTY, FLORIDA

JACKSON County Health Unit was organized September 1, 1935, at Marianna, Fla.—a 6 piece organization consisting of health officer, 3 public health nurses, sanitary inspector, and secretary clerk. Director of the department is Dr. Paul G. Shell, University of Tennessee, 1931. Dr. Shell received training in public health, School of Public Health, Johns Hopkins University, under provision for medical trainees for the Florida State Board of Health by the U. S. Public Health Service, completing that training on June 30.

The department's budget, \$13,000.00, is provided jointly, fifty-fifty, by the County and State Board of Health. Activities are rendered in coöperation with and under the supervision of the State Board of Health, Dr. Henry Hanson, F.A.P.H.A. State Health Officer.

WEST VIRGINIA MEETING

THE West Virginia Public Health Association held its annual program in connection with the sessions of the State Health Officers Conference at

Huntington, October 28 to 30. A program with both information and inspiration was provided which included speakers from outside West Virginia, such as Dr. Iago Galdston of the New York Academy of Medicine; Dr. Paul Padget of Johns Hopkins Medical School; Dr. Kennon Dunham of the University of Cincinnati; Dr. Allen W. Freeman, Dean of the School of Hygiene and Public Health, Johns Hopkins University; Dr. M. V. Ziegler of the U. S. Public Health Service, and Dr. Reginald M. Atwater, Executive Secretary, A.P.H.A.

Separate sessions were held for the health officers, the public health nurses, and the sanitary engineers, and these were followed by a session in which the findings of each group were brought to the attention of the whole conference.

The following officers were elected for the ensuing year:

President, Dr. A. J. Kemper, Clarksburg
1st Vice President, Dr. W. G. C. Hill, Moundsville

2nd Vice President, Dr. R. M. Pedicord, Wheeling

Secretary-Treasurer, Dr. John Thames, Charleston

Representative to the Governing Council, A.P.H.A., Dr. John Thames, Charleston

TEXAS PUBLIC HEALTH ASSOCIATION

THE Texas Public Health Association held its thirteenth annual meeting in Waco, Texas, October 16 to 18. Over two hundred attended the sessions. The first day was devoted to laboratory workers and nurses. The last two days were general sessions. Outstanding speakers were Dr. W. K. Sharpe, Jr., U. S. Public Health Service and William McCraw, Attorney General of Texas.

The next meeting will be held in October, 1936, at Kilgore, Texas. Officers for the ensuing year are: Dr. F. R. Tucker, Nacogdoches, President; Dr. Burke Brewster, Fort Worth, First Vice-President; Edward Robinson, Dal-

las, 2nd Vice-President; Mrs. Ida Levinson, Houston, 3rd Vice-President; H. E. Hargis, 4th Vice-President, and L. E. Bracy, Austin, Secretary-Treasurer.

SOUTHERN BRANCH ELECTS

AT its Fourth Annual Meeting, held November 19-20 in St. Louis, Mo., the Southern Branch elected the following officers for the forthcoming year:

President: I. C. Riggin, M.D., Richmond, Va.

First Vice-President: C. J. Vaughn, M.D., Lexington, Miss.

Second Vice-President: Frances Montgomery, R.N., Montgomery, Ala.

Third Vice-President: M. Z. Bair, Little Rock, Ark.

Secretary-Treasurer: G. Foard McGinnes, M.D., Richmond, Va.

MICHIGAN PUBLIC HEALTH ASSOCIATION

NEWLY elected officers of the Michigan Public Health Association are as follows:

President: Garner M. Byington, M.D., Battle Creek.

Vice-President: J. D. Brook, M.D., Grand Rapids.

Directors (re-elected): Fred M. Meader, M.D., Detroit; C. D. Barrett, M.D., Lansing; John L. Lavan, M.D., Kalamazoo.

New Director added: Dr. David Littlejohn, Midland.

These four directors are in addition to the three directors—Dr. V. K. Volk, of Pontiac, William R. Davis, D.D.S., of Lansing, and Mrs. Hugh Gaston, R.N., of Sault Ste Marie, whose terms end next year.

PERSONALS

DR. FRANK V. CHAPPELL, University of Tennessee—1903, was appointed and has begun his duties as District Health Officer, Jacksonville District, with the Florida State Board of Health, September 1.

Dr. Chappell received training in

public health recently in the School of Public Health, Johns Hopkins University, under provision for medical trainees made available to the Florida State Board of Health by the U. S. Public Health Service. He relieves Dr. Thomas E. Morgan, who, through a fellowship in public health granted by the Rockefeller Foundation, is attending the School of Public Health, regular course, Harvard University.

THOMAS M. RIVERS, M.D., member A.P.H.A., of the Rockefeller Institute for Medical Research, New York, delivered the annual Lilly Heard Anderson Lecture in Pediatrics at the Academy of Medicine in Atlanta, Ga., November 14. His subject was "Virus Diseases of the Central Nervous System."

DR. DAVID L. EDSELL, member A.P.H.A., was given an honorary dinner by the Harvard Medical School Alumni Association, at the Harvard Club of Boston, October 23, on the occasion of his retiring as Dean of the Harvard Medical School and School of Public Health. James B. Conant, LL.D., President of Harvard University, presided, and speakers included A. Lawrence Lowell, LL.D., President Emeritus of Harvard, and Dr. Charles S. Burwell, Dean of the Medical School.

DEATHS

DR. CHARLES E. BANKER, former Chief of the Division of Epidemiology of the New York City Health Department, died November 25. He retired in June, 1935, after 37 years' service with the Department.

HENRY FAIRFIELD OSBORN, Sc.D., President of the American Museum of Natural History, New York, died November 6, at the age of 78.

CONFERENCES

- Dec. 5-7, Annual Conference of the National Society for the Prevention of Blindness, New York, N. Y.
- Dec. 27, American Water Works Association—New York Section, New York, N. Y.
- Dec. 27, 28, Sixteenth Annual Meeting, American Student Health Association; Hotel Pennsylvania, New York, N. Y.
- Dec. 30-31, Fourth Annual Christmas Meeting of the Laboratory Section, Canadian Public Health Association, Toronto, Ont.
- Dec. 30-Jan. 4, 1936, Winter Meeting of the American Association for the Advancement of Science and Associated Societies, St. Louis, Mo.
- Jan. 27-31, 1936, Fourth International Heating and Ventilating Exposition, Chicago, Ill.

- Apr. 1-3, 1936, American Water Works Association—Canadian Section, Hamilton, Ont.
- Apr. 22-25, 1936, National Tuberculosis Association, New Orleans, La.
- May 11-15, 1936, American Medical Association Convention, Kansas City, Mo.
- May 14-16, 1936, American Water Works Association—Pacific Northwest Section, Aberdeen, Washington.
- June, 1936, Seventh Annual Meeting. Western Branch, A.P.H.A., Vancouver and Victoria, B. C.
- June 8-12, 1936, 56th Annual Convention, American Water Works Association, Los Angeles, Calif.
- July 27-31, 1936, Second International Congress on Mental Hygiene, Paris.
- Sept. 8-10, 1936, International Union Against Tuberculosis, Lisbon, Portugal.

Application for Membership

I wish to apply for membership in the American Public Health Association.

Name
Print name in full and give degree

Street and City..... State.....
For correspondence and the Journal

Present public health occupation.....

REQUIREMENTS: Persons professionally engaged or interested in public health work are eligible for election as Members of the Association.

DUES: Dues of Members are \$5.00 per year, which includes an annual subscription to the American Journal of Public Health. Persons joining the Association after July 1 are requested to pay \$7.50, covering a year and one half from July, 1935, to December, 1936.
